chloroform and then allowed to stand, if there be the least proportion of alcohol, will produce a brown tint, deeper in proportion to the quantity, while the chloroform if pure will remain unchanged. To obtain this compound it is sufficient to mix nitrate of potassa and hydrosulphate of ammonia in solution, and to add a solution of protosulphate of iron, stirring constantly, until the liquid has but a slightly alkaline reaction, then evaporating to dryness, treating the residue with etherized alcohol on a filter, and evaporating the liquor so that it may crystallize. (*Journ. de Pharm.*, Sept. 1858, p. 208.) The most injurious impurities are the chlorinated pyrogenous oils, already alluded to. These are different as obtained from methylic or normal chloroform. The oil, obtained by Soubeiran and Mialhe from methylic chloroform, is an oleaginous, yellow liquid, lighter than water, and of a peculiar nauseous empyreumatic odour, perceptible in the methylic chloroform itself. In commercial chloroform it is sometimes present to the amount of 6 per cent. It is easily set on fire, and burns with a smoky flame, chlorine being among the products of its combustion. The oil procured from normal chloroform, which contains it in the amount of about one-fifth of 1 per cent. only, is essentially different from the methylic chloroform oil. It is heavier than water, and has an acrid, penetrating odour, unlike that of the other oil. When the vapour of these oils is inspired or even smelt, it causes, according to Dr. Gregory, distressing sickness and headache. These pyrogenous oils are detected and removed by *pure* and *strong* sulphuric acid. Chloroform, when pure, upon being mixed with an equal volume of this acid, does not colour it; but, when contaminated with these oils, gives the acid a colour, varying from yellow to reddish-brown, according to the amount of impurity. Alcohol also is detected and removed by sulphuric acid. In applying this test, several fluidounces of chloroform should be used; as a slight change of colour cannot be easily seen in a test tube. A still more delicate test of the oily impurities, according to Dr. Gregory, is the smell which they leave. If chloroform, thus contaminated, be poured upon the hand, it quickly evaporates, leaving the oily impurities, recognisable by their offensive odour, now no longer covered by that of the chloroform. The pure substance, rubbed on the skin, quickly evaporates, and scarcely leaves any smell. Chloroform sometimes contains Dutch liquid, which may be discovered by adding an alcoholic solution of potassa; when the mixture, if this impurity be present, will heat, and give off a permanent gas, which is chloride of acetyl, C_4H_3Cl. (*Geuther.*)*

Officinal Tests. The U. S. Pharmacopœia directs that purified chloroform should have a sp. gr. not less than 1·490 nor exceeding 1·494; should boil at 140°; when dropped into water should sink in the form of transparent globules without milkiness; should produce no warmth, sensible to the hand at the moment when mixed, in a bottle closed by a glass stopper, with an equal measure of officinal sulphuric acid, and that, when the liquids have separated on standing, and have been allowed to remain in contact for 24 hours, no colour should be imparted to either, or but a faint yellowish tinge to the acid, forming the lower layer. The Pharmacopœia directs, moreover, that when 3 or 4 fluidrachms are evaporated from a porcelain plate, by causing them to flow to and fro over the surface, the last portions should have a slightly aromatic odour, without pungency or empyreuma, while the plate is covered with a film of moisture, without odour or taste. These tests imply the presence of but a minute proportion of alcohol, and the total absence of chlorine and those volatile and empyreumatic substances which constitute the most injurious impurities of chloroform. A heat that would be felt through the bottle, on the admixture of sulphuric acid with chloroform, would evince the presence of too much alcohol or water. The want

* In relation to chloroform, see the paper of Soubeiran and Mialhe, *Journ. de Pharm.*, July, 1849, copied into the *Am. Journ. of Pharm.*, xxi. 313; also the paper of Dr. Gregory, *Chem. Gaz.*, May 15, 1850.

of discoloration from the contact of the two liquids shows the absence of empyreumatic oily matter; but a very slight discoloration might proceed from the alcohol present, and would not, therefore, be a material objection. A colour bordering on that of madeira wine would imply an objectionable amount of impurities. The volatile impurities are less volatile than chloroform, and would therefore be the last to escape on the evaporation of the liquid. Chloroform, therefore, leaves a foreign odour behind it when allowed to evaporate from the hand, and especially when from a porcelain plate, in the amount and manner indicated; and if it stand this test well, it may be considered as free from any noxious volatile impurity. The slight foreign aroma without pungency, which is given out under these circumstances, is of no injurious significance.*

Medical Properties, &c. When taken *internally*, chloroform acts as a sedative narcotic, probably operating through the nervous system, independently of vascular action or congestion. It has been detected by Ragsky in the blood, and by Dr. Snow, of London, in different parts of the body after death.† In 1848 Dr. H. Hartshorne tried its physiological effects in the dose of seventy-five drops on himself, and found it to produce drowsiness and a general diminution of sensorial power, without exhilaration, or acceleration of the pulse. Since then he has used it internally in a number of cases, and finds it a safe anodyne and soporific, altogether free from the dangerous effects which sometimes follow the inhalation of its vapour. In the dose of a fluidrachm, its soporific effect is about equal to that of thirty-five drops of laudanum. Dr. Hartshorne has given it in doses of from fifty to seventy-five drops every half hour for several hours together. The vehicle used by him is orgeat syrup, in the proportion of two fluidounces to each fluidrachm of the chloroform. When mixed with mucilage of gum arabic, the mixture requires agitation immediately before swallowing each dose.‡

Chloroform, as prepared by Mr. Guthrie, was used internally as early as 1832 by Professor Ives and Dr. Nathan B. Ives, of New Haven, in asthma, spasmodic cough, scarlet fever, and atonic quinsy, with favourable results. (*Silliman's Journ.*, xxi. 406, 407.) It was employed by Dr. Formby, of Liverpool, in hysteria, in 1838; by Mr. Tuson, of London, in cancer and neuralgic affections, in 1843; and by M. Guillot, of Paris, in asthma, in 1844. Dr. L. Dalton, of Logan, Ohio, has found it to possess antiperiodic powers, and employed it successfully in intermittent diseases. Dr. Delioux, of Rochefort, has also proposed it as a remedy in intermittents, given, during the apyrexia, in cases in which the bark and quinia fail to effect a cure. Dr. Aran has employed it for four years with success in lead colic, administered by the mouth and rectum, and applied to the abdomen. In these cases it probably acts by relaxing the intestinal spasm. One of the authors of this work has frequently used it with advantage for the relief of neuralgic and other painful affections, in the dose of from forty to eighty drops, suspended in water by means of gum arabic or yolk of egg. This dose may be repeated, if necessary, at intervals of one or two hours, until some effect on the system is produced. Chloroform has been used internally, with benefit, by Dr. Osburn, of Dublin, in hypochondriasis, and by Dr. Gordon, physician to the Hardwicke Fever Hospital, to allay nervous irritation and procure sleep.

* Much is due to Dr. Squibb for the precision given to the tests for chloroform: and the reader may profitably consult his remarks on the subject in a paper in the *Proceedings of the Pharmaceutical Association*, A. D. 1858, p. 402.

† In relation to the detection of chloroform in the body after death, see the paper of M. Duroy, of Paris, in the *Journ. de Pharm.*, Avril, 1851.

‡ The Society of Pharmacy, of Paris, has given its sanction to the following formula; the French weights being turned into the nearest English weights and measures Take of chloroform ℥ss to ℥j; sugar ℥iij; gum arabic ℥j to ℥ij; water f℥iijss. Rub the chloroform with the sugar in a mortar, then add the gum, and, lastly, by degrees, the water. In this recipe alcohol, which is often inadmissible, is avoided.

A disadvantage connected with the internal use of chloroform is its liability to sicken the stomach, an effect which may sometimes arise from the presence of pyrogenous oil. An incidental advantage is said to be, that it entirely covers the bitterness of other medicines.

Externally, chloroform has been used by Mr. Tuson in cancer, senile gangrene, and sloughing ulcers, and, as an injection and gargle, in discharges from the uterus and foul ulcers of the throat, with the effect of relieving pain, destroying fetor, and promoting the separation of diseased parts. It has also been employed externally, with benefit, in a painful wound of the forearm implicating the radial nerve; by Dr. Legroux in a painful affection of one of the lower extremities, consequent to a cancerous tumour of the pelvis; by Mr. Higginson in labour, applied to the perineum when painfully stretched, and in dysmenorrhœa, brought in contact with the os uteri by means of a sponge; by Dr. Watson in swelled testicle and acute spinal tenderness; by Dr. Hays and Dr. Bond in neuralgia; by the late Dr. I. Parrish in the supra-orbitar pain of rheumatic ophthalmia, and in syphilitic ulceration at the root of the nail; by M. Devergie in papulous eruptions, made into an ointment in the proportion of a fluidrachm to ten drachms of lard; by Prof. Back in the itch; and by M. Chapell in fissure of the anus. It has also been used with success by Dr. Venat, of Bordeaux, in the form of injection, in the commencement of acute gonorrhœa, as an abortive treatment. Dr. Rauch, of Iowa, has employed chloroform topically with decided benefit in neuralgia, colic, and other painful affections. For some purposes he found it useful to incorporate it with olive oil and solution of ammonia, which formed a mixture having effects less transient than those of the uncombined substance. Incorporated in equal measure with the white of eggs, and applied on lint to the gums, it is said to afford great relief in toothache. As a wash, injection, and gargle, Mr. Tuson prepared chloroform diluted with water, in the proportion of one or two drachms to the pint; but, for application to the sound skin, it is generally used undiluted, by means of soft linen, covered with oiled silk to prevent evaporation. When employed in this state it should be pure; as, according to Mialhe, when mixed with absolute alcohol, it acquires caustic properties.

M. Fournié has found that the vapour from a mixture of equal measures of glacial acetic acid and chloroform is even more effectual, as a local anæsthetic, than that of pure chloroform; producing complete insensibility of the skin in five minutes, if applied from a bottle heated simply by the hand. (*Pharm. Journ.*, Jan. 1862, p. 385, from *Comptes Rendus.*)

Chloroform may be gelatinized by agitating it with an equal weight of white of egg in the cold. In three hours it takes the gelatinous form. A stronger preparation may be made by shaking together, in a bottle, four parts of chloroform and one of white of egg, and placing the mixture in water at 140°. In four minutes the gelatinization is completed. *Gelatinized chloroform* may be applied to the skin, spread on linen, or by frictions.

Chloroform, in vapour, may be used as a topical application to the rectum. M. Ehrenreich employed it with success in tenesmus. A drachm may be vaporized by the heat of warm water from a bottle, fitted with a flexible tube, inserted into the bowel. It may be applied to the skin in the form of a vapour douche, according to the method of Dr. Hardy, of Dublin. (See *Ranking's Abstract*, No. 19, 287.) Prof. Langenbeck, of Berlin, prefers chloroform to tincture of iodine, as an injection for the radical cure of hydrocele.

A third method of using chloroform is by *inhalation*. The first case we have met with in which it was thus employed is related by Professor Ives, of New Haven, under date of the 2d of Jan. 1832. The case was one of pulmonic disease, attended with general debility and difficult respiration, and was effectually relieved. (*Silliman's Journ.*, vol. xxi., Jan. 1832, p. 406.) In March, 1847, the action of the pure substance by inhalation was tried on the lower animals, by

M. Flourens, and its effects on the spinal marrow described. In November of the same year, Dr. Simpson, of Edinburgh, after experimenting with a number of anæsthetic agents in order to discover a substitute for ether, tried chloroform at the suggestion of Mr. Waldie, and, having found its effects favourable, brought it forward as a new remedy for pain, by inhalation, in surgery and midwifery. The advantages which he conceived it to possess over ether were the smallness of the dose, its more prompt action, more agreeable effects, less tenacious odour, greater cheapness, and greater facility of exhibition.

The usual effects produced by a full dose of chloroform, administered by inhalation, are the rapid production of coma, relaxation of the muscles, slow and often stertorous breathing, upturning of the eyes, and total insensibility to agents which ordinarily produce acute pain. The effect on the heart's action is variable. Sometimes frothing of the mouth takes place, and, more rarely, convulsive twitches of the face and limbs. The insensibility is generally produced in one or two minutes, and usually continues for five or ten minutes; but the effect may be kept up for many hours, provided the inhalation be cautiously renewed from time to time. The immediate effects of the agent are followed by a drowsy state, sometimes by quiet sleep. As a general rule, no recollection is retained of anything that occurred during the state of insensibility. Experience has shown that the effects, here described as those of a full dose of chloroform by inhalation, cannot be induced without danger to life. Hence all prudent surgeons will be content with an impression short of the abolition of all consciousness. It is generally admitted that, at a certain stage of anæsthesia, there is insensibility to pain, while consciousness to a certain extent remains; and it is this condition that the surgeon should aim to produce. According to Mr. Skey, chloroform had been administered up to 1854, in 9000 cases in St. Bartholomew's Hospital, without a single accident, a fact which must be taken as proof of its careful employment in that institution. The delicate operation of extracting the cataract has been facilitated by its use, in the hands of Mr. Bowman, of London; and, in general, the performance of operations on the eyeball is greatly assisted by the insensibility produced, especially in children. In partial anchylosis, in which the surgeon proposes to break up the adhesions by force, chloroform, like ether, takes off the muscular resistance, and renders the manipulations painless. It is asserted to be an advantage of chloroform in surgical operations, that less blood is lost. If this assertion should prove to be true, there will be greater necessity of delaying the dressings until reaction shall have taken place. The question whether the use of chloroform in the major operations of surgery is favourable or otherwise to recovery, has been examined by an appeal to statistics. Dr. Simpson, of Edinburgh, thinks the percentage of recoveries has been increased by its use; while Dr. Arnott, basing his opinions on the results of operations in the London hospitals, holds the contrary opinion.

The advantages and disadvantages of chloroform, when compared with ether as an anæsthetic in operative surgery, have not been satisfactorily determined; but on one point the evidence appears to be conclusive, namely, that it is far more dangerous to life than ether. According to Dr. Snow, of London, the vapour in the air breathed by the patient should not exceed 6 per cent. Dr. Gilman, of New York, thinks that chloroform has a more sudden and powerful effect than under ordinary circumstances, when inhaled immediately after bleeding; a fact which he explains by the increased power of absorption produced by the loss of blood. (*N. Y. Med. Times*, Oct. 1852.)

Sometimes chloroform produces unpleasant remote effects; such as abolition of smell, perversion of taste, and loss of tonicity in the bladder and rectum. Two cases, illustrative of these effects, in which chloroform was inhaled in excess, are related by Dr. Happoldt in the *Charleston Med. Journ.* for Jan. 1856.

In midwifery, chloroform has been extensively employed to relieve pain and

facilitate labour, since it was first recommended by Dr. Simpson. Its effects are similar to those of ether; and each agent has its exclusive advocates among those practitioners of midwifery who are willing to use anæsthetics. According to Dr. Atthill, of Dublin, the use of chloroform produces a tendency to post-partum hemorrhage. Dr. Robert Lee, of London, has cited seventeen cases, in which it was supposed to produce various pernicious effects in labour. (*Lancet*, Dec. 24, 1853.) Notwithstanding exceptional cases of injury, it is every year growing in favour as an anæsthetic in parturition. The profession is unanimous as to its great utility in instrumental labours.

The dose of chloroform for inhalation is a fluidrachm, equivalent to 220 drops or more, to be repeated in two minutes, if the desired effect should fail to be produced. The most convenient inhaler is a handkerchief, loosely twisted into the form of a bird's nest, which, after having been imbued with the chloroform, is held to the mouth and nose. The use of this simple inhaler ensures a due admixture of atmospheric air with the vapour of the chloroform. The moment insensibility is produced, which should be brought on *gradually*, the inhalation should be suspended; and, if consciousness return too soon, it should be cautiously renewed. In all cases an experienced assistant should attend to the administration of the chloroform and to nothing else, watching the state of the respiration and pulse. The moment there is the least snoring or failure of the pulse, the vapour should be withdrawn. Chloroform should not be administered to persons subject to epilepsy, affected with organic disease of the heart, or predisposed to syncope.*

Chloroform, as ordinarily prepared, is apt to produce, when inhaled, headache, nausea, and even vomiting. Perfectly pure chloroform, according to Soubeiran and Mialhe, does not produce these disagreeable effects, which are plausibly attributed to the presence of the pyrogenous oils. Dr. Simpson, however, finds that the purest chloroform that he uses not unfrequently causes vomiting; but Dr. Gregory attributes this effect, when following the use of the pure substance, to its administration after a full meal, which should always be avoided.

Chloroform having proved to be a relaxing agent and remedy for pain, when used by inhalation in surgery and midwifery, it was natural that its effects should be tried in the same way in spasmodic and painful diseases. Accordingly, it has been inhaled in hiccough, chorea, hooping-cough, hysteria, the paroxysm of asthma, angina pectoris, nephritic colic, tetanus, poisoning from strychnia, hydrophobia, and the paroxysm of tic douloureux, and generally with decided advantage. In Germany it has been praised in bronchitis and pneumonia as an expectorant and calming remedy. It has been employed also with success for the reduction of strangulated hernia. Mr. R. J. Mackenzie, of Edinburgh, bears testimony to its goods effects, used by inhalation, in spasmodic stricture of the urethra, attended with retention of urine. Sometimes the urine is caused to flow at once; and, when this is not the case, the passage of the catheter is facilitated. Dr. Cain, of Charleston, found it very useful in spasmodic obstruction of the bowels, promptly relieving pain, and favouring the action of enemata. As a soporific it has been given beneficially in delirium tremens, and in the noisy forms of chronic insanity.

Much has been said in relation to the dangers attendant upon the inhalation of chloroform, and, certainly, many more deaths have been reported from its use than from that of ether. The late Dr. Warren, of Boston, published, in 1849, the details of ten cases, in which death was caused by chloroform, all occurring in little more than a year, and many other fatal cases have since occurred; and he declared that, if he were compelled to substitute chloroform for ether in inha-

* For rules laid down by M. Baudens for the administration of chloroform, see the *Am. Journ. of Med. Sci.* for Jan. 1854, p. 208; and for those given by M. Robert, surgeon to the Hospital Beaujon, see *Ranking's Abstract*, No. 19, p. 116.

lation, he would do it with much anxiety. Chloroform is unquestionably a more powerful agent than ether, and acts not only differently, but in a much smaller dose. The comparative smallness of its dose is certainly a ground of danger, when its administration falls into reckless or incompetent hands. In view of the greater danger from the use of chloroform as an anæsthetic, the governors of the Massachusetts General Hospital have prohibited the use of any other agent than ether in surgical operations.

When the effects of chloroform inhalation proceed too far, the remedies are a horizontal posture, cold air fanned upon the face, cold water poured upon the head, sinapisms to the feet, frictions and heat to the body and extremities, and ammonia to the nostrils. If respiration ceases, the tongue should be seized with the artery-forceps, and pulled forward from off the glottis, and artificial respiration attempted by blowing into the mouth, and by other appropriate measures. When the patient can swallow, strong coffee may be given with advantage. Galvanic electricity, passed through needles inserted in different parts of the body, is recommended by M. Abeille, of Ajaccio, as a powerful means of recalling sensibility; and it is highly probable that the electro-magnetic battery would prove useful. When an overdose is taken by the mouth, the same remedies may be employed, with the addition of the stomach-pump, when vomiting cannot be produced. In a case of suicide by swallowing chloroform, in which death took place in about thirty-four hours, the lining membrane of the larynx and trachea were found inflamed, the bronchi were loaded with a dirty-gray purulent fluid, the lungs were inflamed as in the first stage of pneumonia, and the brain and its membranes congested. In another fatal case, reported by Dr. J. Williams, of the Philadelphia Hospital, Blockley, in which the patient survived thirty-seven hours, no morbid appearances were observed worthy of note.

In relation to the preparations, consisting of chloroform and alcohol, which have been used under the name of "chloric ether," the reader is referred to *Spiritus Chloroformi* in *Part II.**

Pharm. Uses. In preparing Atropia.

Off. Prep. Linimentum Chloroformi; Liquor Gutta-perchæ, *U. S.*; Mistura Chloroformi, *U. S.*; Spiritus Chloroformi. B.

OLEUM ÆTHEREUM. *U. S. Ethereal Oil.*

"Take of Stronger Alcohol *two pints;* Sulphuric Acid *sixty-one troyounces;* Distilled Water *a fluidounce;* Stronger Ether *a sufficient quantity.* Add the Acid slowly to the Alcohol, mix them thoroughly, and allow the mixture to stand for twelve hours. Decant the clear liquid from the sediment into a tubulated retort, of such capacity that the mixture shall nearly fill it. Adapt a thermometer tube to the tubulure by means of a cork, so that the bulb shall be deeply immersed in the liquid, and, having attached a Liebig's condenser, distil, by means of a sand-bath, at a temperature between 312° and 322°, until the liquid ceases to come over, or until a black froth begins to arise in the retort. Separate the yellow ethereal liquid from the distillate, and expose it for twenty-four hours, in a shallow capsule, to evaporate spontaneously. Then transfer the remaining liquid to a wet filter; and, when the watery portion has drained off, wash the oil which is left, while on the filter, with the Distilled Water. When this also has drained off, transfer the oil to a graduated measure, by perforating the point

* *Chlorodyn.* An empirical preparation under this name has been extensively used in London, and has recently acquired some general notoriety from having been the reputed cause of death in a recent case of accidental poisoning in England, and as having produced very threatening symptoms in another case, in which the patient was saved. From a formula published in the *Am. Journ. of Pharm.*, March, 1860 (p. 181), it would appear to consist of chloroform, chloric ether (so called), tincture of capsicum, oil of peppermint, muriate of morphia, hydrocyanic acid (Scheele's), perchloric acid, tincture of Indian hemp, and molasses; and of these powerful medicines, moreover, in such proportions as to make one shudder at the idea of its unregulated use.—*Note to the twelfth edition.*

of the filter, and add to it an equal volume of Stronger Ether. The Ethereal Oil, obtained by this formula, measures about six fluidrachms." *U. S.*

In the late consolidation of the British Pharmacopœias, this valuable remedy was omitted, partly on account of the uncertainty as to its special antispasmodic virtues, partly from its expensiveness when properly made and its liability to spontaneous change, and partly, moreover, because not only is it often adulterated, but other compounds are substituted for it. (*Med. Times and Gaz.*, March, 1864, p. 248.) It is, however, retained in the U. S. Pharmacopœia, with certain modifications in the process, which, it is hoped, may enable it to yield a larger and more reliable product.

In the existing U. S. formula, the first change to be noticed is the direction, after the mixture of the acid and alcohol, to decant the clear liquid from the sediment, which is sulphate of lead, deposited by the acid on account of its dilution. According to Dr. Squibb, the presence of the sulphate of lead in the retort causes the mixture to froth over, and thus necessitate a suspension of the process so much sooner, as greatly to lessen the amount of product the materials are capable of affording. The increase of oil resulting from this simple modification of the process is said to be one-third. Another new feature is the introduction of a thermometer into the retort, whereby the important point is obtained of properly regulating the temperature, which, in order to the due reaction of the materials, should not fall below 312° nor rise above 322°. Again, the washing of the oil with solution of potassa has been omitted, because the alkali was found to decompose a portion of the oil, and the sulphurous acid, which it was intended to neutralize, can be separated by the washing with distilled water now directed. By wetting the filter, the oil is prevented from passing along with the water. Finally, the oil is now ordered to be diluted with an equal measure of stronger ether, as this has been found to contribute greatly to its preservation.

When alcohol is distilled with a large excess of sulphuric acid, the same products are generated as those mentioned, in the article upon ether, as being formed towards the close of the distillation of that liquid. (See *page* 949.) These were stated to be sulphurous acid, heavy oil of wine, olefiant gas, and resino-carbonaceous matter. In the U. S. process such an excess of sulphuric acid is employed for the purpose of obtaining the oil. The product of the distillation is generally in two layers, one, consisting of water holding sulphurous acid in solution, and the other, of ether containing the heavy oil of wine. According to the experience of Dr. Squibb, the sp. gr. of these two layers is so nearly equal, that sometimes one and sometimes the other is uppermost; so that the direction in the old formula to separate the supernatant liquor is incorrect, and has been superseded by the present, to separate the yellow ethereal liquid; the colour and other sensible properties being considered sufficiently distinctive. After separation, the liquid is exposed for twenty-four hours to the air, in order to dissipate the ether by evaporation; and the oil which is left is washed with water to deprive it of all traces of sulphurous acid.

The nature and mode of formation of heavy oil of wine are not well understood. It has been explained, in a preceding article, that, in the early stage of the distillation of a mixture of sulphuric acid and alcohol, sulphovinic acid, or the double sulphate of ether and water, is formed. During its progress this is decomposed so as to yield ether. When, however, the alcohol is distilled with a large excess of sulphuric acid, the sulphovinic acid is decomposed so as to form a small quantity of the heavy oil of wine, now considered to be a double sulphate of ether and ethylen, having the formula $C_4H_5O,SO_3+C_4H_4,SO_3$. It is conceived to be generated from two eqs. of sulphovinic acid (double sulphate of ether and water), which are resolved into one eq. of heavy oil of wine, two of sulphuric acid, and three of water. When the heavy oil is gently heated with four parts of water, sulphovinic acid is reproduced, and the separated ethylen

floats on the surface as an oily substance, called, when thus isolated, light oil of wine. *Light oil of wine*, as thus obtained, is a pale-yellow oil, supposed to have the formula C_4H_4. As ordinarily procured in the process for preparing ether, it contains a portion of that substance. When the pure light oil of wine is kept, it deposits a stearoptene, isomeric with itself, called concrete oil of wine, or oil of wine camphor; after which the oil is changed, and takes the name of etherole. *Etherole* is a pale-yellow oily liquid, having an aromatic odour. Its sp. gr. is 0·921, boiling point 536°, and freezing point 31° below zero. It communicates a greasy stain to paper. *Concrete oil of wine*, sometimes called *etherine*, crystallizes in long, transparent, brilliant, tasteless prisms, soluble in alcohol and ether, insoluble in water, fusible at 230°, boiling at 500°, and having the sp. gr. 0·980. Dr. Squibb takes a different view of the composition of ethereal oil, and believes it, instead of a sulphate or double sulphate, to be a sulphovinate of a carbohydrogen base; and for this reason, that it fails, especially when pure and recent, to give any of the characteristic reactions of sulphuric acid or the sulphates. (*Am. Journ. of Pharm.*, Jan. 1861, p. 58.)

Properties. The undiluted *ethereal oil* (*heavy oil of wine*) is a yellowish neutral liquid, possessing an oleaginous consistency, a penetrating aromatic odour, and rather sharp and bitter taste. It boils at 536°. Its sp. gr. is, according to the U. S. Pharmacopœia of 1850, 1·096; according to the London College, after Mr. Hennell's results, 1·05. The density obtained by Dr. Squibb, U. S. Navy, by following the old formula of the U. S. Pharmacopœia exactly, was 1·129. By Dumas and Serullas its density is stated to be as high as 1·133, which is probably the more correct number for the *pure* oil. When dropped into water it sinks, assuming the form of a globule. It dissolves sparingly in cold water, moderately in hot water, and readily in alcohol and ether. It is devoid of acid reaction, the sulphuric acid present in it being completely neutralized by the ether and ethylen united with it. The sulphuric acid present is not precipitated by the usual reagents for this acid; because they furnish a base, which, replacing the ethylen, gives rise to one of the salts of sulphovinic acid, all of which are soluble in water and hydrous alcohol. The U. S. ethereal oil of the existing Pharmacopœia is the proper oil diluted with an equal volume of stronger ether. This gives it an ethereal odour in addition to that characteristic of the pure oil, and considerably reduces its sp. gr., which is now stated at 0·91. The process by which the officinal oil of wine is formed yields but a small product, being, according to the Pharmacopœia, only about six fluidrachms, or somewhat more than a fortieth, by measure, of the alcohol employed.

In the officinal ethereal oil, the heavy oil of wine, that is, the double sulphate of ether and ethylen is not only diluted with an equal measure of ether, but is mixed also with variable proportions of free light oil of wine (ethylen), in addition to that present in it as one of the essential constituents of the heavy oil. This fact accounts for the different densities assigned to the heavy oil.

The heavy oil undiluted is liable to spontaneous change by time, being not only rendered brown, but chemically altered so as to separate into two layers. But this tendency is in great measure obviated, in the officinal ethereal oil, by the preservative influence of the ether. It may be kept long without other appreciable change than the acquisition of a brown hue, which does not interfere with its medical virtues. It should not, when tested by dry litmus paper, evince the presence of any free acid.

The article, sold in our shops as ethereal oil, is too often a mixture of alcohol and ether, containing but a trace of the oil. Four samples of so-called ethereal oil, as imported from England, were examined by Mr. E. N. Kent, of New York, and found to have the composition above stated. (*N. Y. Journ. of Pharm.*, i. 65.) The ethereal oil is used only for the preparation of the Compound Spirit of Ether or Hoffmann's anodyne, which, when properly made, is a very valuable

medicine; and it is much to be regretted that due attention has not been paid by the manufacturing chemists to the furnishing of a good ethereal oil to the apothecary. It is necessarily an expensive preparation; but this does not justify the substitution for it of a cheaper and nearly worthless article under the same name

Preparation of Aloes.

ALOE PURIFICATA. *U. S. Purified Aloes.*

"Take of Socotrine Aloes *twenty-four troyounces;* Stronger Alcohol *four fluidounces.* Heat the aloes, by means of a water-bath, until it is completely melted. Then add the Alcohol, and, having stirred the mixture thoroughly, strain it through a fine sieve, which has just been dipped into boiling water. Evaporate the strained mixture by means of a water-bath, constantly stirring, until a thread of the liquid becomes brittle on cooling. Lastly, break the product when cold into pieces of a convenient size, and keep it in a well-stopped bottle." *U. S.*

Aloes, even of good quality, is so often mixed as found in the market with various accidental impurities, such as fragments of wood, vegetable remains, pieces of leather, and earthy matter, that it has been thought advisable to have an officinal process by which it may be freed from these, should its purification be found necessary in any particular instance. This is especially the case with Socotrine aloes, which, from the want of proper supervision in its preparation, is probably more liable to these impurities than the Cape or Barbadoes aloes; but, as these are also sometimes impure, there seems to be no good reason why they should have been officinally excluded from the benefits of the process.

The use of alcohol in the formula is simply to render the melted aloes more liquid, and thus facilitate the straining; and it is subsequently got rid of by evaporation: but care should be taken not to use too great a heat, or to continue it too long, for fear of impairing the virtue of the drug.

Thus prepared, aloes is in angular fragments, brittle, of a brownish or reddish-brown colour, and of the agreeable aromatic odour of Socotrine aloes. It is nearly all soluble in alcohol. W.

ALUMEN.

Preparations of Alum.

ALUMEN EXSICCATUM. *U. S., Br. Dried Alum.*

"Take of Alum, in coarse powder, *four troyounces.* Expose it, in a suitable vessel, to a temperature not exceeding 450° until the residue weighs two troyounces and one hundred and twenty grains; then reduce it when cold to fine powder." *U. S.*

"Take of Alum *four ounces.* Heat the Alum in a porcelain capsule till it liquefies, raise and continue the heat till aqueous vapour ceases to be disengaged, and then reduce the residue to powder." *Br.*

The object of these processes is to obtain the alum free from its water of crystallization, without otherwise in the least decomposing it. For this purpose a certain degree of heat is necessary; and yet, if the heat be too great, the salt itself is decomposed, and the desired end is not attained. If the alum employed be the potassa-alum, the old indefinite directions will generally be sufficient to secure the requisite result, as this salt will resist a heat short of redness; but this is not the case with the ammonia-alum, which, on account of its greater cheapness, has almost excluded the former salt from the market, and, there is

reason to apprehend, may sometimes be substituted for the potassa-alum, though this is the one officinally directed. To guard against failure from this cause, the present U. S. Pharmacopœia prescribes 450° as the highest heat to be employed, and checks the operation when nearly all the water has been driven off, as indicated by the weight of the residue. Mr. John M. Maisch has satisfactorily determined by experiment that, whichever alum may be used, this temperature is quite high enough; and the direction of the Pharmacopœia, as to the weight of the residue, ensures that a sufficient heat will be employed. By the officinal process half a drachm or about 4 per cent. of the water of crystallization, supposing the salt employed to be the potassa-alum, is left behind; and Mr. Maisch has ascertained that this in no degree injures the properties of the dried salt. (*Am. Journ. of Pharm.*, Jan. 1860, p. 21.) In the case of the ammonia-alum, as this salt contains a somewhat larger proportion of water, the limitation as to the quantity expelled still further secures against the employment of too great a heat.

Properties. Dried alum, sometimes called *alumen ustum* or *burnt alum*, is in the form of an opaque white powder, possessing a more astringent taste than the crystallized salt. Before pulverization, it is a light, white, opaque, porous mass. During the exsiccation, alum loses from 41 to 46 per cent. of its weight in dissipated water. Dried alum resists the action of water for a long time, showing its altered aggregation. It is, however, if properly prepared, at length wholly dissolved by cold water, while 6 parts of boiling water dissolve it in a short time; and this may be considered as a sufficient test that the salt has not been decomposed. (*Maisch.*) In composition it differs from crystallized alum merely in the absence of water.

Medical Properties and Uses. Dried alum has been given in obstinate constipation, with the effect of gently moving the bowels, and affording great relief from pain. (See *Alumen.*) The dose is from five to ten grains or more. Its principal medical use is as an escharotic for destroying fungous flesh. B.

ALUMINÆ SULPHAS. *U. S. Sulphate of Alumina.*

"Take of Sulphate of Alumina and Ammonia, Carbonate of Soda, each, *four troyounces:* Sulphuric Acid *a troyounce and one hundred and fifty grains;* Water *a sufficient quantity.* Dissolve the salts separately, each in six fluidounces of boiling Water, and pour the solution of the Sulphate gradually into that of the Carbonate; then digest with a gentle heat until the evolution of carbonic acid ceases. Collect upon a filter the precipitate formed, and wash it with water until the washings are no longer affected by chloride of barium. Next, with the aid of heat, dissolve the precipitate in the Sulphuric Acid, previously diluted with half a pint of Water, and, having filtered the solution, evaporate it until a pellicle begins to form. Then remove it to a water-bath, and continue the evaporation, with constant stirring, until a dry salt remains. Lastly, preserve this in a well-stopped bottle." *U. S.*

In the above process it is the ammonia-alum that is used. The soda of the carbonate unites with the sulphuric acid of the tersulphate of alumina, with the escape of the carbonic acid, and the precipitation of the alumina in the form of a hydrate; while the undecomposed sulphate of ammonia of the alum, and the newly formed sulphate of soda remain in solution. The alumina is then washed in order to separate any portion of the sulphates adhering to it, the absence of which is shown by the non-action of chloride of barium on the washings. It now remains to unite the hydrate of alumina and sulphuric acid, which is effected by heating them with water; and the salt, which is formed in solution, is obtained by evaporating the solution to dryness. It may also be obtained from the solution by the addition of alcohol, which precipitates it. In the process the several substances are used in very nearly saturating proportions.

Sulphate of alumina may be prepared also by the process of MM. Hurla and Brunel, which consists in exposing, in an iron cylinder, sulphate of alumina and

ammonia (ammonia-alum), first dried to separate its water of crystallization, to a cherry-red heat. Sulphate of alumina remains in the cylinder, and the volatilized products are collected in water. The chief of these is sulphite of ammonia, which serves for the preparation of a fresh portion of alum, after having been changed into the sulphate by oxidation in the air. (*Chem. Gaz.*, Sept 15, 1852, p. 359.)

Properties. As procured by the officinal process, sulphate of alumina is in the form of a white powder. It may, however, be obtained in lamellar crystals. As seen in commerce, it is usually in flattened crystalline cakes, which appear as though formed by the cooling of soft masses of minute crystals. It has a sour, as well as sweet and very astringent taste, is soluble in twice its weight of water, and has an acid reaction. It consists of one eq. of alumina, which is a sesquioxide of aluminium, and three eqs. of sulphuric acid ($Al_2O_3 3SO_3$), and, when crystallized, contains 18 eqs. of water. The salt is, therefore, a tersulphate of alumina. It is known to be a sulphate by giving a precipitate with chloride of barium insoluble in nitric acid, and a salt of alumina by forming octohedral crystals of alum when its solution is evaporated with sulphate of potassa or ammonia. In consequence of its strong affinity for potassa, it is coming into use in the arts as a means of separating that alkali. (*Wattl.*)

Medical Properties and Uses. This salt is used only externally, as an astringent and antiseptic. The salts of alumina generally have the property of opposing animal putrefaction; but the sulphate is practically preferred. It has been used extensively in the Philadelphia Hospital, Blockley, at the suggestion of Dr. Dunglison, as an antiseptic and detergent application to ulcers, and with favourable results. The late Dr. Pennypacker reported several cases in which it proved useful. The strength of the solution employed varied from ℥ijss to ℥iij of the salt to f℥vi of water, according to the state of the ulcer. Dr. G. Johnson, of Georgia, found the solution attended with the happiest effects, used as an injection in fetid discharges from the vagina. (*Med. Exam.*, vi. 63 and 112.) M. Homolle employs a saturated solution with much advantage as a mild caustic in enlarged tonsils, nasal polypi, nævi, scrofulous and cancerous ulcers, diseases of the os uteri, and various chronic enlargements. He applies it daily by means of a hair pencil. He has sometimes found the solution to answer still better by the addition of oxide of zinc. Solution of sulphate of alumina is capable of dissolving a considerable quantity of recently precipitated gelatinous alumina. Such a solution, impregnated with benzoin, has been proposed by M. Mentel as a hemostatic, under the name of *benzinated solution of alumina.* It resembles the styptic liquid of Pagliari. (See *page* 166.) It is prepared by saturating, with gelatinous alumina, a solution made of eight ounces of sulphate of alumina dissolved in a pint of water. To the saturated solution six drachms of bruised amygdaloid benzoin are added, and the whole is kept at a temperature of about 150° for six hours, with occasional agitation; so that the liquid, after filtration, may have about the density 1·26. This liquid, put in a cool place for several days, so as to deposit some crystals of alum, forms the benzinated solution, remarkable for its very sweet odour, and astringent balsamic taste. Benzinated solution of alumina, diluted in the proportion of from two to five fluidrachms to the pint of water, has been found useful as an injection in leucorrhœa, and in ulcerations of the neck of the uterus, accompanied by fetid discharges. (See *Am. Journ. of Pharm.*, March, 1857, p. 128.)

The aqueous solution of sulphate of alumina was found by M. Gannal to be effectual in preserving bodies for dissection, when injected into the blood-vessels. In summer the bodies were preserved fresh for twenty days or more; in winter, for three months. For use in winter, a quantity of the solution, sufficient for injecting one body, may be made by adding a pound, avoirdupois, of the salt to a quart of water; in warm weather, the solution must be stronger. B

AMMONIA.

Preparations of Ammonia.

In the present edition of the U. S. Pharmacopœia, all the liquid preparations of ammonia are arranged under other heads; and we follow the example of that work in making a similar disposition of them here. Hence, the reader will find the *Water of Ammonia* (Solution of Ammonia, U. S. 1850) under the AQUÆ or *Waters; Solution of Acetate of Ammonia* under the LIQUORES or *Solutions;* and the *Spirit* and *Aromatic Spirit of Ammonia* under the SPIRITUS or *Spirits.*

AMMONIÆ BENZOAS. *Br. Benzoate of Ammonia.*

"Take of Solution of Ammonia *three fluidounces* [Imperial measure]; Benzoic Acid *two ounces* [avoirdupois]; Distilled Water *eight fluidounces.* Dissolve the Benzoic Acid in the Solution of Ammonia previously mixed with the Water; evaporate at a gentle heat; and set aside that crystals may form." *Br.*

Although the amount of ammonia ordered in the formula is in excess, yet, from the feeble affinity between the constituents, and the consequent escape of ammonia during the evaporation, a portion of the acid benzoate is formed, if the officinal directions are strictly complied with. This result, however, may be obviated by adding a little solution of ammonia from time to time during or near the close of the evaporation, so as to maintain the alkali in slight excess. The crystals, moreover, should be dried without heat. Professor Procter informs us that half the quantity of water directed in the formula, moderately heated, readily dissolves the acid after the addition of ammonia, and, on cooling, deposits crystals of the benzoate. If slightly evaporated, and then allowed to cool, the solution becomes a mass of crystals, retaining so much water as to render it necessary to dry them by bibulous paper.

Properties. A specimen of this salt, prepared at our request by Prof. Procter, precisely in accordance with the directions of the Br. Pharmacopœia, is in minute white, glistening, extremely thin four-sided laminæ, having a slight odour of officinal benzoic acid, and a bitter, saline, somewhat balsamic taste, leaving a slight but persistent sense of acrimony on the tongue. The salt is soluble in water and alcohol, and when heated sublimes without residue; but is probably changed into the acid benzoate. Gmelin states that, if the solution be boiled, the salt is converted into the acid benzoate, which crystallizes in feathery tufts of needles. (*Handbook*, xii. 38.) According to Lichtenstein, it deliquesces in the air. It consists of one eq. of ammonia, one of benzoic acid, and two eqs. of water; one of the eqs. of water being derived from the acid and the other from the base, so that its formula is $NH_3.C_{14}H_5O_3+2HO$. But the Br. Pharmacopœia, considering hydrated ammonia as oxide of ammonium, gives the formula NH_4O, $C_{14}H_5O_3+HO$. It gives a copious yellow precipitate with the salts of sesquioxide of iron; and is known to contain benzoic acid and ammonia, by depositing the former when the solution is acidulated with muriatic acid, and giving off the latter when it is heated with potassa. (*Br.*) According to Mr. Squire, it is the acid salt that is commonly met with in the shops, which is less soluble than the officinal salt, requiring 60 parts of water and 12 of alcohol for solution. This is a decided objection to it.

Medical Properties and Uses. Benzoate of ammonia is a slightly stimulant diuretic, but acts chiefly through its benzoic acid, being decomposed by the gastric acids, which combine with the ammonia, while the benzoic acid is absorbed, and passes out through the kidneys in the form of hippuric acid. Under benzoic acid, it has been stated that the proportion of urea is diminished at the same time, giving rise to the supposition that the nitrogen of the hippuric acid is derived from that source. Dr. Garrod suggests that, as the elements of hippuric acid are the same as those of benzoic acid and glycocoll the hippuric

acid may be formed by a direct combination of these substances. The salt has been found useful as a diuretic in defective action of the kidneys, as an alterative to the mucous membrane of the urinary passages in chronic inflammation of that tissue, and as a solvent of the phosphatic deposits, through the hippuric acid into which it is converted. It has been employed in gouty affections with a view to the removal of the deposits of urate of soda about the joints; but it has been shown to have no effect on the elimination of uric acid. The salt does not appear to produce any injurious effects even in considerable quantities. (Garrod, *Med. Times and Gaz.*, Feb. 1864, p. 146.) The dose is from 10 to 30 grains, which may be taken dissolved in water. W.

AMMONIÆ PHOSPHAS. *Br. Phosphate of Ammonia.*

"Take of Strong Solution of Ammonia *eight fluidounces;* Diluted Phosphoric Acid *twenty fluidounces.* Add the Solution of Ammonia to the Phosphoric Acid; dissolve by a gentle heat the crystalline precipitate which forms; and set the solution aside that crystals may again form. Remove the crystals, and, having dried them quickly on filtering paper placed on a porous brick, preserve them in a stoppered bottle. The mother liquor, if evaporated to half its bulk, will, upon being mixed with two fluidounces of Strong Solution of Ammonia, give additional crystals." *Br.*

This, like the preceding salt of ammonia, is a new officinal of the Br. Pharmacopœia. According to the above process it is formed by a direct union of its constituents. The amount of water in the materials employed not being sufficient to hold in solution the whole of the phosphate formed, a portion of the salt crystallizes. This is redissolved by a gentle heat, which is probably intended to produce a more thorough union of the ingredients. Upon cooling, there is a copious deposition of crystals; but, as much of the salt remains in the mother-liquor, a new crop of crystals is obtained by concentrating the liquid, and adding a further quantity of solution of ammonia. This is necessary in order to supply the place of the ammonia lost by volatilization, and to secure the particular salt intended. The variety of phosphoric acid employed in this formula is the tribasic, which forms three salts with ammonia, one containing 3 eqs. of ammonia without basic water, which may be called the subphosphate, the second, two eqs. of ammonia and one of basic water, forming the neutral phosphate, and the third, one eq. of ammonia and two of basic water, forming the acid phosphate. The first of these is the one intended by the British Council, and is represented by the formula $3NH_4O,PO_5+5HO$. To prepare it, a constant excess of ammonia must be maintained, and this is done by compliance with the process, if the materials are of due strength. Without such a precaution, more or less of one of the other salts would be generated, in consequence of the escape of the alkali. For the same reason, it is necessary to avoid heat in the concentration; and hence the solutions of the acid and alkali employed are of such strength that the water they contain is insufficient to hold the resulting salt in solution, which, therefore, crystallizes without evaporation. Nevertheless, from the want of this precaution or from other cause, phosphate of ammonia of the shops is generally either the neutral or acid phosphate, or a mixture of the two.

Properties. The officinal salt of the Br. Pharmacopœia ($3NH_4O,PO_5+5HO$, or *phosphate of the oxide of ammonium with 5 eqs. of water*) is in large colourless, transparent prisms, which have a slight ammoniacal odour, and, on exposure to the air, lose both ammonia and water, and become opaque. The salt is soluble in two parts of water (*Squire*), and its solution, if dilute, is not disagreeable to the taste. (*Garrod.*) It is insoluble in alcohol. When treated with caustic potassa it evolves ammonia, and with nitrate of silver gives a canary-yellow precipitate, indicating that the acid is the tribasic phosphoric acid. "If 20 grains be dissolved in water, and the solution of ammonio-sulphate of magnesia be added, a crystalline precipitate falls, which, when well washed on a filter with solution of

ammonia, diluted with an equal volume of water, dried, and heated to redness, leaves 11·44 grains." (*Br.*) The residue is pyrophosphate of magnesia, and its amount indicates the quantity of phosphoric acid contained in the salt.

But, as before stated, this is not the salt usually found in the shops, which is either the neutral or acid phosphate, or a mixture of the two. The neutral salt ($2NH_4O,HO,PO_5+HO$) may be made by saturating the excess of acid in superphosphate of lime by means of carbonate of ammonia. Phosphate of lime is precipitated, and phosphate of ammonia obtained in solution, which, being duly concentrated by a gentle heat, affords the salt in crystals upon cooling. The method of obtaining the superphosphate of lime is given under the head of phosphate of soda. (See *Sodæ Phosphas.*) This variety of phosphate of ammonia is a white salt, crystallizing in six-sided tables, derived from oblique quadrangular prisms, efflorescent, soluble in alcohol, and in 4 parts of cold water. The solution has an alkaline somewhat saline taste, and an alkaline reaction, and gives out ammonia when heated. (Bridges, *Fownes' Chem.*, Am. ed., p. 234.)

The acid phosphate ($NH_4O,2HO,PO_5+4HO$) is obtained by boiling a solution of either of the other salts so long as ammonia escapes, and then crystallizing. Its crystals are four-sided prisms, permanent in the air, of an acid taste and reaction, and soluble in 5 parts of cold water. (*Bridges.*) In a specimen of the common phosphate of ammonia of the shops which came under our notice, we recognised both the tabular crystals of the neutral phosphate with two eqs. of ammonia, having a saline slightly acrid taste, and neutral in reaction, and the prism of the acid salt, with a sour and saline taste and decided acid reaction. W.

Medical Properties and Uses. This salt was first brought to the notice of the profession, as a remedy for gout and rheumatism, by Dr. T. H. Buckler, of Baltimore, in a paper published in the *Am. Journal of the Medical Sciences* for Jan. 1846. In this paper a number of cases of these diseases are reported, which were treated mainly by this remedy by Dr. Buckler and several of his medical friends, and with apparently good effects. Dr. Buckler was led to employ the salt on theoretical grounds. He conceived that the "matter of gout" consisted of two salts, the urates of soda and lime, existing in the blood; and that the phosphate of ammonia, by reacting with them, would give rise to soluble salts. The new salts formed, if the double decomposition should take place, would be urate of ammonia, and the phosphates of soda and lime. Unfortunately for this theory, as furnishing the means of eliminating uric acid, urate of ammonia is not more soluble than urate of soda. Nevertheless, apart from all theory, the therapeutic powers of phosphate of ammonia deserve to be investigated. Since the publication of Dr. Buckler's paper, several practitioners, both in this country and in Europe, have employed the remedy with apparently useful results in chronic gout, and certain urinary diseases. The dose of the salt is from ten to forty grains, three or four times a day, dissolved in a tablespoonful of water. B.

AMMONIÆ VALERIANAS. *U. S. Valerianate of Ammonia.*

"Take of Valerianic Acid *four fluidounces.* From a mixture, placed in a suitable vessel, of Muriate of Ammonia, in coarse powder, and an equal weight of Lime, previously slaked and in powder, obtain gaseous ammonia, and cause it to pass, first through a bottle filled with pieces of Lime, and afterwards into the Valerianic Acid, contained in a tall, narrow, glass vessel, until the Acid is neutralized. Then discontinue the process, and set the vessel aside that the Valerianate of Ammonia may crystallize. Lastly, break the salt into pieces, drain it in a glass funnel, dry it on bibulous paper, and keep it in a well-stopped bottle." *U. S.*

This is a new officinal of the U. S. Pharmacopœia. Much difficulty was experienced by manufacturing chemists in procuring crystallized valerianate of ammonia, until, after a series of experiments, Mr. B. J. Crew, of Philadelphia, ascertained that it was necessary to employ the monohydrated valerianic acid,

as the ordinary acid with three eqs. of water could not be successfully employed for the purpose. The officinal formula is based upon that of Mr. Crew, published in the *Am. Journ. of Pharm.* (March, 1860, p. 109). In this formula the monohydrated valerianic acid, procured by a special process (see *Acidum Valerianicum*, page 942), is saturated with gaseous ammonia obtained in the usual manner from a mixture of muriate of ammonia and lime. The saturation is known to have been effected when litmus paper is no longer acted on. During the operation heat is developed sufficient to prevent premature crystallization, and, when the saturation is completed, nothing more is necessary than to allow the solution to cool. Crystallization soon begins, and in a few hours the contents of the vessel become a nearly solid mass of crystals.

Properties. Thus prepared, valerianate of ammonia is in snow-white, pearly, four-sided, tabular crystals, perfectly dry, of an offensive odour like that of valerianic acid, and a sharp sweetish taste. Instead of deliquescing, whenever exposed to the air, as happened to the salt formerly procured, it undergoes this change only in a moist atmosphere, and effloresces when the air is dry. It is very soluble both in water and alcohol. Exposed to heat it is in great measure volatilized unchanged; but a small portion, by giving off a part of its ammonia, is converted into the acid valerianate. Its formula, viewed as a salt of hydrated ammonia, is $NH_3HO,C_{10}H_9O_3$, as a salt of oxide of ammonium NH_4O, $C_{10}H_9O_3$. It is known to be a salt of ammonia by giving off this gas when treated with potassa, and of valerianic acid by the separation of this acid, and its appearance on the surface in the form of an oil, when the salt is decomposed in solution by a mineral acid. W.

Medical Properties. Valerianate of ammonia is not poisonous. Given to dogs in the dose of 150 grains, it produced no inconvenience. As a therapeutic agent it was first brought to the notice of the profession, in 1856, by M. Déclat, of Paris, who published a paper in that year, going to show its remarkable efficacy in the treatment of neuralgia. The preparation which he used was a solution of valerianate of ammonia of uniform strength, made according to the recipe of M. Pierlot, an apothecary of Paris, which had been extensively given to the epileptics of the Salpêtrière and the Bicêtre. Since then it has been used in various diseases, principally of the nervous system; such as hysteria, epilepsy, chorea, &c. The favourable report of its efficacy in neuralgia, made by M. Déclat, has been confirmed by practitioners in Paris, London, and Dublin. The dose of the salt is from two to eight grains, dissolved in water. As now prepared, it may be made into pills without inconvenience; and, properly coated so as to conceal their disagreeable odour, they are probably the best form for the administration of the salt. M. Pierlot made his solution, mentioned above, by dissolving *a drachm* of valerianic acid in *thirty-two drachms* of distilled water, saturating the solution with carbonate of ammonia, and adding to the salt formed, *two scruples* of the alcoholic extract of valerian. According to M. Pierlot, the latter addition is necessary in order to preserve the preparation from change; for a simple solution of the ammoniacal salt is rapidly decomposed. It will keep still better if the extract, when added to the solution, be mixed with a fluidounce of diluted alcohol, while but 24 drachms of distilled water are used, so as to preserve the measure. The solution of M. Pierlot is neutral, of a brown colour, and a strong odour of valerian. It contains 1-25th of its weight of the pure salt. The dose is from six to thirty drops, given in water or on a lump of sugar. (*Ann. de Thérap.*, 1857, p. 55.)* B.

* *Elixir of Valerianate of Ammonia.* Various attempts have been made to prepare a formula for the exhibition of valerianate of ammonia, which shall in some measure cover its offensiveness. The following, which has been considerably used in this city, under the name above given, is perhaps as suitable as any that has been proposed. Take of Valerianate of Ammonia ʒi; Fluid Extract of Vanilla fʒss; Compound Tincture of Cardamom fʒvi, Curaçoa fʒij, Water fʒiv. Mix. Dose, a teaspoonful three times a day.

ANTIMONIUM.

Preparations of Antimony.

In arranging the Preparations of Antimony, it has been deemed expedient to follow the example of the Pharmacopœias, in placing them in a strictly alphabetical order; and, as relates to the *Solution of Terchloride of Antimony* and the *Wine of Antimony*, to obey the same authority in transferring them, the one to the *Solutions*, the other to the *Wines*, where they properly belong through the character of their menstrua.

ANTIMONII ET POTASSÆ TARTRAS. *U. S.* ANTIMONIUM TARTARATUM. *Br.* ANTIMONIUM TARTARIZATUM. *Ed., Dub. Tartrate of Antimony and Potassa. Tartarated Antimony. Tartarized Antimony. Tartar Emetic.*

"Take of Oxide of Antimony, in very fine powder, *two troyounces;* Bitartrate of Potassa, in very fine powder, *two troyounces and a half;* Distilled Water *eighteen fluidounces.* To the Water, heated to the boiling point in a glass vessel, add the powders, previously mixed, and boil for an hour; then filter the liquid while hot, and set it aside that crystals may form. Lastly, dry the crystals, and keep them in a well-stopped bottle. By further evaporation the mother-water may be made to yield more crystals, which should be purified by a second crystallization." *U. S.*

"Take of Oxide of Antimony *five ounces* [avoirdupois]; Acid Tartrate of Potash, in fine powder, *six ounces* [avoird.]; Distilled Water *two pints* [Imperial measure]. Mix the Oxide of Antimony and Tartrate of Potash with sufficient Distilled Water to form a paste, and set aside for twenty-four hours. Then add the remainder of the Water and boil for a quarter of an hour, stirring frequently. Filter, and set aside the clear filtrate to crystallize. Pour off the mother-liquor, evaporate to one-third, and set aside that more crystals may form. Dry the crystals on filtering paper at the temperature of the air." *Br.*

This preparation is a double salt, consisting of tartrate of potassa, united with tartrate of teroxide of antimony. The principle of its formation is exceedingly simple, being merely the saturation of the excess of acid in the bitartrate (cream of tartar) with the teroxide. The officinal processes consist in boiling a mixture of cream of tartar and of pure teroxide obtained by a distinct process. (See *Antimonii Oxidum.*) This conforms with the formula of the late Dublin Pharmacopœia, and is an improvement of the U. S. formula of 1850, in which the *oxychloride of antimony, or powder of Algaroth*, was the form of oxide used, and was prepared from the sulphuret as the first step of the process.

In the late London formula the teroxide used was in the form of disulphate of antimony, which was originally proposed by the late Mr. Phillips, so early as 1811. It was prepared in the following manner. By gently heating sulphuric acid with tersulphuret of antimony, the metal was teroxidized at the expense of part of the acid, sulphurous acid was evolved, and sulphur set free. By gradually increasing the heat until dryness was produced, the whole of the sulphurous acid was driven off, the free sulphur was burnt out, and nothing remained but the teroxide, united with sulphuric acid in the form of tersulphate of teroxide of antimony. This, by continued washing, was converted into the anhydrous disulphate of the teroxide ($2SbO_3,SO_3$). (*Phillips.*) The disulphate was then mixed with cream of tartar in the proportion of nine parts by weight to ten, and the mixture boiled with water in the usual manner. This process is an eligible one, and has the merit of being economical. According to Mr. Phillips, it affords "a very pure and beautiful salt."

In the preparation of tartar emetic several circumstances should be taken into view. The cream of tartar should not be in excess; as in that case it is apt to

crystallize, upon cooling, with the tartar emetic. To avoid such a result it is better to have a slight excess of antimonial oxide. No rule is applicable to the determination of the proper proportion of water, except that it should be sufficient to dissolve the tartar emetic formed. The hot filtration, directed in the U. S. Pharmacopœia, may be conveniently performed by means of the tin apparatus, devised by Dr. Hare for filtering liquids at the point of ebullition. (See pp. 881, 882.) The U. S. Pharmacopœia boils for an hour; the British for fifteen minutes. In all cases the salt should be obtained in well defined crystals, unmixed with those of cream of tartar, as the best index of its purity. The practice of some manufacturing chemists of boiling the filtered liquor to dryness, whereby an impure mass is obtained, consisting in part only of the antimonial salt, is very reprehensible.

It is not easy to decide as to the relative eligibility of the different forms of antimonial oxide, used for preparing tartar emetic. The preference, however, was given to the oxychloride (*powder of Algaroth*) by Berzelius; and M. Henry, an eminent pharmaceutist of Paris, after a careful comparison of the different processes, declared also in its favour. This testimony in favour of the oxychloride induced the revisers of our national Pharmacopœia, in 1830, to adopt it for making tartar emetic; but it was abandoned at the late revision, and the pure oxide was adopted in its place, in conformity with the Dublin formula, which is that of the Br. Pharmacopœia; so that the two Pharmacopœias are in accordance in the mode of preparing this important salt.

M. Henry has given a process for preparing tartar emetic with the oxychloride on a large scale; and, as his formula may be useful to the manufacturing chemist, we subjoin it, turning the French weights into the nearest *apothecaries'* weights and measures. Take of prepared sulphuret of antimony, in very fine powder, three pounds four ounces; muriatic acid, marking 22° (sp. gr. 1·178), eighteen pounds and a half; nitric acid, two ounces and a half. Introduce the sulphuret into a glass matrass, of a capacity double the volume of the mixture to be formed; and add to it from three to five pounds of the acids previously mixed, so that the sulphuret may be thoroughly penetrated by them; then add the remainder of the acids. Place the matrass on a sand-bath, and heat the mixture gradually to ebullition, avoiding the vapours, which are disengaged in large quantity. Continue the heat until the vapours given off are so far deprived of sulphuretted hydrogen as not to blacken white paper moistened with solution of acetate of lead; after which allow the liquor to cool, and to remain at rest until it has become clear. Decant the clear liquor, and, in order to procure the portion of liquid which may be retained by the moist residue, add to this a small portion of muriatic acid, and again decant. Mix the decanted liquids, which consist of a solution of terchloride of antimony, and add them to a large quantity of water, in order that the oxychloride may be precipitated; taking care, during their addition, to stir constantly in order that the precipitated powder may be more minutely divided, to facilitate its subsequent washing. To determine whether the water has been sufficient to decompose the whole of the terchloride, a part of the supernatant liquid, after the subsidence of the powder, is to be added to a fresh portion of water; and, if a precipitate take place, more water must be added to the mixture, so as to obtain the largest possible product of oxychloride. The precipitation being completely effected, wash the powder repeatedly with water, until this no longer affects litmus, and place it on linen to drain for twenty-four hours. The quantity of oxychloride thus obtained will be about three pounds and a half in the moist state, or two pounds nine ounces when dry. Assuming it to be this quantity, mix it with three pounds eleven ounces of cream of tartar, in fine powder, and add the mixture to two gallons and five pints of boiling water, contained in an iron kettle. Concentrate the liquor rapidly until it marks 25° of Baumé's hydrometer for salts, and then fil-

ter. By repose the liquor furnishes a crop of very pure crystals, which require only to be dried. The mother-waters are treated in the following manner. Saturate the excess of acid with chalk, filter, and concentrate to 25°. By cooling a second crop of crystals will be obtained; and, by proceeding in a similar manner, even a third crop. But these crystals are somewhat coloured, and must be purified by recrystallization.

In relation to the above process, it may be observed that the proportion of oxychloride and cream of tartar must be adjusted according to the numbers given, on the assumption that the former is dry; but it by no means follows that the whole of the oxide should be dried. To proceed thus would be a waste of time. The mode of proceeding is to weigh the whole of the moist oxide, and afterwards to weigh a small part of it, and ascertain how much this loses in drying. Then, by a calculation, it is easy to determine how much the whole of the moist oxide would weigh in the dry state.

Tartar emetic is not usually prepared by the apothecary, but made on a large scale by the manufacturing chemist. Different processes are pursued in different manufactories; and it is not material what plan is adopted, provided the crystals of the antimonial salt are carefully purified. In an extensive manufactory in London, antimony ash (see *page* 122) is employed for boiling with the cream of tartar, and it is stated to form the cheapest material for making tartar emetic. (*Pereira's Mat. Med.*) Mohr prefers the use of a *moist* oxide, prepared by adding gradually an intimate mixture of one part, each, of tersulphuret of antimony and nitrate of potassa, to a boiling mixture of one part of sulphuric acid and two of water. The liquid is boiled down nearly to dryness and allowed to cool. The grayish-white mass, thus formed, is then washed thoroughly with water. The details of this process are given by Soubeiran, by whom it is praised, in the *Journ. de Pharm.*, 3e sér., iii. 327.

Properties, &c. Tartrate of antimony and potassa was discovered in 1631 by Adrian de Mynsicht. It is in the form of transparent, colourless crystals, which possess a nauseous, metallic, styptic taste, and have usually the form of rhombic octohedrons. When prepared from the oxychloride it crystallizes in tetrahedrons. As it occurs in the shops, it is in the form of a white powder, resulting from the pulverization of the crystals. The crystals, when exposed to the air, effloresce slightly, and become white and opaque. They are insoluble in alcohol, but dissolve in proof spirit or wine.* (See *Vinum Antimonii.*) They are soluble in about 15 parts of water at 60° (in 20 parts, U. S., Br.), and in between 2 and 3 parts of boiling water. The late Dr. Perceval, of Dublin, alleged that good tartar emetic dissolves in twelve parts of water, and this statement agrees nearly with the results of Brandes, who found it to be soluble in 12·65 parts of water at 70°. Its aqueous solution slightly reddens litmus, and undergoes decomposition by keeping. If one-fifth of its bulk of alcohol be added to the water, the decomposition is prevented. It is incompatible with acids, alkalies and their carbonates, some of the earths and metals, chloride of calcium, and acetate and subacetate of lead. It is incompatible also with astringent infusions and decoctions, as of rhubarb, cinchona, catechu, galls, &c.; but these substances, unless galls be an exception, do not render it inert, though they lessen its activity to a greater or less extent.

Characteristics and Tests of Purity. Tartar emetic, when pure, exhibits its appropriate crystalline form. A crystal or two, dropped into a solution of hydrosulphuric acid, will be covered with an orange-coloured deposit of tersulphuret of antimony; and hydrosulphuric acid gas causes an orange-red precipitate with

* Alcohol precipitates it from its aqueous solution, and Mr. T. S. Wiegand proposes as a convenient method of obtaining it in fine powder, to boil an ounce of it in four times its weight of water, and to pour the solution into a pint and a half of 95 per cent. alcohol. (*Am. Journ. of Pharm.*, Sept. 1858, p. 407.)

its solution. One hundred grains of the salt, dissolved in water, yield forty-nine grains of tersulphuret with this test. (*Lond. Pharm.*, 1851.) "An Imperial fluid ounce of distilled water (437·5 grains) dissolves 20 grains at 60° without residue; and the solution gives with sulphuretted hydrogen an orange precipitate, which, when washed and dried at 212°, weighs 9·91 grains." (*Br.*) Entire solubility in water is not a character belonging exclusively to the pure salt, for according to the late Mr. Hennell, tartar emetic may contain 10 per cent. of uncombined cream of tartar, and yet be wholly soluble in the proper proportion of water. (*Phillips.*) This being the case, the character, given in the U. S. and Edinburgh Pharmacopœias, of entire solubility in twenty parts of water, is not to be depended upon. A dilute solution is not precipitated by chloride of barium or nitrate of silver, nor rendered blue by ferrocyanide of potassium. A solution, containing one part of the salt in forty of water, is not disturbed by an equal volume of a solution of eight parts of acetate of lead in thirty-two of water and fifteen of acetic acid. This test is adopted in the U. S. Pharmacopœia from the Edinburgh, and is intended to show the absence of uncombined bitartrate of potassa; for, when the acidulated acetate is used as here directed, it does not form the white tartrate of lead with the pure antimonial salt, but only with the bitartrate, when this happens to be present. The acidulated acetate is said to be capable of detecting 1 per cent. of this impurity in tartar emetic; but Dr. Christison finds difficulties in using this test which render it too precarious for practice. Mr. Hennell's method of detecting uncombined bitartrate, is to add a few drops of a solution of carbonate of soda to a boiling solution of the antimonial salt. If the precipitate formed is not redissolved, no bitartrate is present.

The impurities found in tartar emetic are uncombined cream of tartar from faulty preparation or fraudulent admixture, tartrate of lime, iron, sulphates, and chlorides. The mode of detecting cream of tartar has been indicated above. Tartrate of lime is derived from the cream of tartar, which always contains this impurity. It is apt to form on the surface of the crystals of tartar emetic in crystalline tufts, which are easily brushed off. Iron is sometimes present, especially when the antimonial salt has been prepared from glass of antimony. It is detected by a blue colour being *immediately* produced by ferrocyanide of potassium, added after a little acetic acid. If the blue colour be *slowly* produced, it may arise from reactions on the iron of the ferrocyanide itself. If much iron be present, the solution of the tartar emetic will be yellow instead of colourless. Sulphates are detected by chloride of barium. The presence of a chloride is shown by a precipitate being produced by nitrate of silver, added to a dilute solution. According to Serullas, tartar emetic, except when well crystallized, and all the other antimonial preparations usually contain a minute proportion of arsenic, derived from the native tersulphuret of antimony, which almost always contains this dangerous metal. For the mode of detecting it, see *Acidum Arseniosum.* Tartar emetic should always be bought by the apothecary in good crystals, in which state the salt is pure, or very nearly so, and entirely free from arsenic. Its powder is perfectly white; and, when it is yellowish-white, iron is probably present. It is said that some druggists ignorantly prefer a tartar emetic which is yellowish-white in powder.

It has been already stated, in general terms, that tartar emetic in solution is incompatible with acids and alkalies, and with some of the earths; but this salt is so important, that some details in regard to the effects of particular reagents, included under these titles, seem to be necessary. Muriatic and sulphuric acids, added to a solution of the antimonial salt, not too dilute, throw down a white precipitate of terchloride or subsulphate of antimony, mixed with cream of tartar, which is redissolved by an excess of the precipitant. Nitric acid throws down a subnitrate, which is taken up by an excess of it. When caustic potassa is added to a tolerably concentrated solution, it produces at first no effect, then a precipi-

tate of teroxide, and afterwards the solution of this precipitate, if the addition of the alkali be continued. Lime-water acts in a weaker solution, and throws down a white precipitate, consisting of the mixed tartrates of lime and antimony. Carbonate of potassa affects still weaker solutions, throwing down a white precipitate of teroxide; but this test does not act in solutions containing less than a quarter of a grain to the fluidounce. Ammonia, both pure and carbonated, precipitates a solution of tartar emetic, throwing down the pure teroxide. To these reagents may be added infusion of galls, which, when fresh and strong, causes a dirty, yellowish-white precipitate of tannate of teroxide of antimony.

Composition. Tartar emetic consists of two eqs. of tartaric acid 132, one of potassa 47·2, one of teroxide of antimony 153, and two of water 18 = 350·2. It is evident that it contains tartaric acid and potassa in the proportion to form bitartrate of potassa or cream of tartar; and, accordingly, it may be viewed as a compound of one eq. of cream of tartar, and one of antimonial teroxide. The excess of acid in the bitartrate may be considered as united with the teroxide; and on that view it is a double salt, composed of tartrate of potassa, with tartrate of teroxide of antimony. The U. S. name assumes it to be a double salt. According to the view of the bibasic character of tartaric acid, which now begins to prevail, tartar emetic consists of one eq., each, of teroxide of antimony, potassa, and tartaric acid, with two eqs. of water ($SbO_3,KO,C_8H_4O_{10}+2HO$); the equivalent number of the acid being doubled.

Medical Properties and Uses. Tartrate of antimony and potassa is the most important of the antimonials, and is capable of fulfilling numerous indications in disease. Its general action is that of a sedative to the circulation; while, on the contrary, it excites most of the secretions. According to the dose, and the peculiar circumstances under which it is administered, it acts variously as an alterative, diaphoretic, diuretic, expectorant, purgative, and emetic. In *minute* doses it is employed with a view to its alterative effects, and has been found useful in diseases of the skin. In such doses it has been given with alleged benefit in various chronic pulmonary affections, but especially in phthisis. In phthisical cases it was prescribed in this way, in 1818, by Lanthois, of Montpellier, and sometimes with advantage; and afterwards, with encouraging results, by others. In the beginning of phthisis, the remedy, in these minute doses, may have exercised a meliorating effect by its influence on the bronchial inflammation which so constantly attends this disease. In *small* doses, mostly associated with saline remedies, such as nitre or sulphate of magnesia, and assisted by copious dilution, it is frequently resorted to in febrile complaints, for the purpose of producing perspiration, which is often freely induced, especially if the remedy gives rise to nausea. If the surface be exposed to cool air, so as to constrict the pores, the tendency will be to the kidneys, with the effect of producing an increased flow of urine. It also proves useful, on many occasions, in pulmonary and bronchial disease as an expectorant; and with a view to its action in this way, it is conjoined with squill, ammoniac, and similar remedies. In *full* doses it acts as an emetic, and is characterized by certainty, strength, and permanency of operation. It remains longer in the stomach than ipecacuanha, produces more frequent and longer continued efforts to vomit, and exerts a more powerful impression on the system. The nausea and attendant prostration are often very considerable. As an emetic its use is indicated where the object is not merely to evacuate the stomach, but to agitate and compress the liver and other abdominal viscera. By the extension of its action to the duodenum, it often causes copious discharges of bile, and may thus prove useful when there is a morbid excess of that secretion. It is employed as an emetic in jaundice, hooping-cough, and croup, and in several diseases of the nervous system, such as mania, amaurosis, tic douloureux, &c. In efforts to reduce old dislocations, its relaxing power over the muscles when it nauseates, is taken advantage of, to facilitate the operation. Tartar emetic often incident

ally produces purging. In reference to this tendency, practitioners are in the habit of adding it to purgatives, the operation of which it promotes in a remarkable degree. It is contraindicated in diseases of great debility, in the advanced stages of febrile affections, and in fevers with irritability of stomach.

Of late years, on the continent of Europe, and to some extent in Great Britain and this country, tartar emetic has been given in *large* doses, with a view to its sedative, or, as it is usually termed, *contrastimulant* operation. This practice originated with Rasori, professor of clinical medicine at Milan, who published his views in 1800. The principal diseases in which it has been thus used are pneumonia, pleurisy, bronchitis, acute rheumatism, especially of the joints, articular dropsies, chorea, hydrocephalus, and apoplexy. The medicine is directed in doses, varying from a grain to two grains or more, every two hours, dissolved in a small quantity of water; the patient being restricted in the use of drinks whilst under its operation. It is stated that, when the remedy is thus given in diseases of high action, it seldom produces vomiting, an effect which the author of the practice wished to avoid. The power of the system to bear large doses of tartar emetic, during the existence of acute diseases, was considered by Rasori to depend upon the coexisting morbid excitement, and the capability of bearing them was expressed by the term *tolerance*. It is in pneumonia especially that the contrastimulant practice has most advocates. It is admitted to have the effect of lowering the force and frequency of the pulse, and the rapidity of the respirations; and, in not a few instances, produces marked remedial effects. In pleurisy and bronchitis, the advantages of the same practice are less decided. Though we are disposed to admit the controlling influence of tartar emetic, when thus exhibited, in the diseases named; yet we by no means think that its use should supersede blood-letting, or even form our chief reliance. In cases, however, in which blood-letting, both general and local, has no effect, or has been carried as far as the circumstances of the case will warrant, tartar emetic, administered on the contrastimulant plan, may be found useful. In croup the remedy proves efficacious not merely by the free vomiting which it produces, but, if given in large doses, on the contrastimulant principle. If the tolerance cannot be otherwise established, laudanum may be conjoined with the antimonial, in order to bring it about. In the treatment of articular dropsies, the decided benefit derived from large doses of tartar emetic is fully shown by M. Gimelle, who has reported twenty-eight successful cases. The medicine was gradually increased from four grains to sixteen or twenty daily, and, generally, the tolerance was established on the first day. The effusion was absorbed in a space of time varying from eight to sixteen days. Tartar emetic has been used with success in delirium tremens; the antimonial being sometimes given alone, at other times conjoined with opium or laudanum. This practice originated with the late Dr. Joseph Klapp, of this city.

Tartar emetic, in the form of enema, has been used with great benefit, in rigidity of the os uteri, by Dr. James Young, and by Dr. H. R. Storer, of Boston. The formula employed by Dr. Young was one grain of the antimonial salt to six fluidounces of warm water.

Externally, tartar emetic is often employed as a counter-irritant, mixed with lard or cerate, or in the form of a plaster. (See *Unguentum Antimonii* and *Emplastrum Antimonii*.) It causes, after a longer or shorter interval, a burning sensation, accompanied by a peculiar and painful pustular eruption. This mode of producing counter-irritation is serviceable in a number of diseases; but particularly in deep-seated pains, spinal irritation, hooping-cough, and chronic inflammation of the chest threatening consumption. Care must be taken, when the salt is applied by means of a plaster, that the pustular inflammation does not proceed too far; as, in that event, it produces deep and very painful ulcerations, difficult to heal. According to M. Guérin, inflamed parts exhibit a condition of

tolerance to the local effects of tartar emetic, evinced by the absence of pustulation. In support of this view, he asserts that he has treated hundreds of cases of acute arthralgia with tartar emetic ointment with the best effects, mostly without the production of any eruption; and, when the pustules were produced, the benefit accrued before they appeared. When no pustulation follows, M. Guérin supposes that the antimony acts by absorption.

Tartar emetic is generally given in solution, and in an amount which varies with the object in view in its administration. Its dose as an alterative is from the thirty-second to the sixteenth of a grain; as a diaphoretic or expectorant, from the twelfth to the sixth of a grain; and as a nauseating sudorific, from a quarter to half a grain; repeated, according to circumstances, every hour, two, or four hours. With a view to its alterative effect, a pint of water, containing from one-quarter to half a grain, may be taken daily as drink. If required to act as a purgative, a grain may be dissolved in half a pint of water with an ounce of Epsom salt, and two tablespoonfuls of the solution given every two or three hours. As an emetic the full dose is from two to three grains; though it is usually given in the dose of a grain, dissolved in a tablespoonful of water, repeated every ten or fifteen minutes till it vomits; the operation being aided by warm water or chamomile tea. It is often conjoined with ipecacuanha, in the proportion of one or two grains to twenty of that emetic. For convenient administration in small doses, the Pharmacopœias direct it dissolved in wine. It is given very conveniently to children in dilute aqueous solution, which, being nearly tasteless, is readily taken by them. In all cases it should be used with caution; as it sometimes acts even in small doses with unexpected violence.

Effects as a Poison. The symptoms of acute poisoning by tartar emetic are an austere metallic taste; nausea; copious vomiting; frequent hiccough; burning pain in the stomach; colic; frequent stools and tenesmus; fainting; small, contracted, and accelerated pulse; coldness of the skin; sometimes intense heat; difficult respiration; loss of sense; convulsive movements; very painful cramps in the legs; prostration, and death. Ten grains is the smallest dose reported to have proved fatal. To the above effects is sometimes added difficulty of deglutition. Occasionally vomiting and purging do not take place; and, when they are absent, the other symptoms are aggravated. Sometimes a pustular eruption is produced, like that caused by the external application of the antimonial; as in a case reported by Dr. J. T. Gleaves, of Tennessee. These are the effects, observed in different cases, on the healthy economy; but doses which, taken in health, would prove fatal, are sometimes borne with safety in certain morbid states of the system, attended with acute inflammation.

The effects of slow poisoning by tartar emetic on inferior animals have been carefully studied by Dr. B. W. Richardson, of London, and Dr. Nevins, of Liverpool. All the surfaces absorb the solution of the salt, and the metal is found in all the tissues after death, except that of the brain; but most abundantly in that of the liver. The elimination of the poison is effected by all the secreting organs, but especially by the kidneys. The tolerance of antimony is attributed by Dr Richardson to the eliminating action of these glands. The pathological appearances are general congestion, marked fluidity of the blood, and intense vascularity of the stomach and sometimes of the rectum, but without ulceration. No other pulmonary lesion occurs but simple congestion. (See *Am. Journ. of Med. Sci.*, Jan. 1857, p. 266.) The general results obtained by Dr. Richardson are confirmed by the experiments of Dr. Nevins. (*Pharm. Journ.*, Feb 1857, p. 415.)

In treating a case of poisoning by tartar emetic, if it is found that the patient has not vomited, immediate recourse must be had to tickling the throat with a feather, and the use of abundance of warm water. Usually, however, the vomiting is excessive and distressing; and here it is necessary to use remedies calculated to decompose the poison, and to allay the pain and irritation. To effect the

former object, astringent decoctions and infusions, such as of Peruvian bark and common tea, are recommended as antidotes. These, however, act but imperfectly, according to M. Toulmouche, who found that a decoction of cinchona had usually no power in lessening the emetic effect of this antimonial. Similar observations had been made by Dr. Clutterbuck. (*Pereira.*) The decoction of galls acts more decidedly; but M. Toulmouche accords the preference to the galls in substance. A case of poisoning with half an ounce of tartar emetic, successfully treated with copious draughts of green tea and large doses of tannin, is reported by Dr. S. A. McCreery, of the U. S. Navy. (*Am. Journ. of Med. Sci.*, Jan. 1853, p. 131.) Galls no doubt act by their tannin, which forms, with the antimonial part of the salt, the insoluble and probably inert tannate of antimony. To stop the vomiting and relieve pain, laudanum should be given, either by the mouth or by injection, and to combat consecutive inflammation, leeches to the epigastrium and other antiphlogistic measures may be resorted to.

After death from suspected poisoning by tartar emetic, it is necessary to search for the poison in the body. The contents of the stomach should be digested in water, acidulated with muriatic and tartaric acids. The former acid will serve to coagulate organic matter; the latter to give complete solubility to the antimony. The solution obtained, after having been filtered, should be subjected to a stream of sulphuretted hydrogen, which, if tartar emetic be present, will throw down the orange-red tersulphuret of antimony, distinguished from tersulphuret of arsenic and all other precipitates by forming with hot muriatic acid a solution, from which, when added to water, a white curdy precipitate of oxychloride of antimony (powder of Algaroth) is thrown down. Sulphuretted hydrogen is by far the most delicate test for tartar emetic.

Sometimes the antimony cannot be found in the stomach and bowels, and yet may exist in other parts. When it leaves the alimentary canal, it has been found by Orfila especially in the liver and kidneys, and their secretions. The mode of extracting the antimony, recommended by Orfila, is to carbonize the dried viscera with pure concentrated nitric acid in a porcelain capsule, to boil the charred mass obtained for half an hour with muriatic acid, assisted with a little nitric acid, to filter the liquor, and introduce it into Marsh's apparatus. Antimoniuretted hydrogen will be formed, which, being inflamed, will deposit the antimony on a cold surface of porcelain as a black stain, distinguishable from the similar stain produced by arsenic by its less volatility, and by its forming, with hot muriatic acid, a solution which affords a white precipitate of oxychloride of antimony when added to water.

Reinsch's process is a good one for separating antimony from the tissues, and was first used for that purpose by Dr. Alfred Taylor, of London. (See *page* 34.) The tissues are boiled in muriatic acid, and a bright slip of copper is immersed in the hot solution. The metallic film, deposited on the copper, must be proved to be antimony. This is done by Dr. Odling by first boiling the coated copper in a solution of permanganate of potassa, with a little excess of potassa, for a few minutes, whereby the antimony becomes oxidized and dissolved, and then passing sulphuretted hydrogen through the filtered and acidulated solution. The characteristic orange-red precipitate of tersulphuret of antimony is produced, which may be tested for antimony as above mentioned. Mr. H. H. Watson has simplified Dr. Odling's process by dispensing with the use of the permanganate of potassa. He subjects the coated copper slip, in a tube, to a boiling very dilute solution of caustic potassa, the metal being alternately drawn out of and immersed in the solution, by the aid of a copper wire, until the whole of the coating is oxidized and dissolved. The solution is then treated as directed by Dr. Odling. (*Med. Times and Gaz*, July, 1857, page 613.)

ANTIMONII OXIDUM. *U. S.*, *Br.* *Oxide of Antimony.*

"Take of Sulphuret of Antimony, in very fine powder, *four troyounces;* Muriatic Acid *eighteen troyounces;* Nitric Acid *a troyounce and one hundred and twenty grains;* Water of Ammonia *a fluidounce and a half;* Water, Distilled Water, each, *a sufficient quantity.* Introduce the Sulphuret into a flask, of the capacity of two pints, and, having added the Muriatic Acid, digest, by means of a sand-bath, until effervescence ceases. Then, having removed the flask from the sand-bath, add the Nitric Acid gradually; and, when nitrous acid vapours cease to be given off, and the liquid has grown cold, add to it half a pint of Water, and filter. Pour the filtered liquid gradually into twelve pints of Water, constantly stirring, and allow the precipitate to subside. Decant the supernatant liquid, and wash the precipitate twice by decantation, using, each time, eight pints of Water. Then transfer it to a muslin filter to drain, and, after the draining is completed, wash it with Water until the washings cease to have an acid reaction. Next introduce it into a suitable vessel, and subject it to the action of the Water of Ammonia for two hours; at the end of which time, transfer it to a moistened muslin filter, and wash it with Distilled Water as long as the washings produce a precipitate with nitrate of silver. Lastly, dry the precipitate upon bibulous paper with the aid of a gentle heat." *U. S.*

"Take of Solution of Terchloride of Antimony *sixteen fluidounces;* Carbonate of Soda *five ounces* [avoirdupois]; Water *two gallons* [Imperial measure]; Distilled Water *a sufficiency.* Pour the Antimonial Solution into the Water, mix thoroughly, and set aside until the precipitate which forms shall have subsided. Remove the supernatant liquid by a siphon, add one gallon [Imp. meas.] of Distilled Water, agitate well, let the precipitate subside, again withdraw the fluid, and repeat the process of affusion of Distilled Water, agitation, and subsidence, until the fluid has only a feeble acid reaction on litmus paper. To the precipitate add the Carbonate of Soda previously dissolved in two pints [Imp. meas.] of Distilled Water, leave them in contact for half an hour, stirring frequently, collect the deposit on a calico filter, and wash with boiling distilled water until the washings cease to give a precipitate with a solution of nitrate of silver acidulated by nitric acid. Lastly, dry the product at a heat not exceeding 212°." *Br.*

In the U. S. formula the solution of terchloride is prepared as the first step of the proceedings; in the British is taken already formed, as the result of a distinct process. When tersulphuret of antimony is digested with muriatic acid, an interchange of principles takes place; the hydrogen of the acid uniting with the sulphur of the antimonial, and escaping as sulphuretted hydrogen, while the chlorine and antimony combine to form terchloride of antimony which is held in solution. The effect of the nitric acid is supposed to be to render the oxide whiter, by decomposing any remaining sulphuretted hydrogen, and thus preventing it from contaminating the product. Though the result thus far is an aqueous solution of the terchloride, this cannot be diluted beyond a certain degree without decomposition. Hence, if largely diluted, as when poured into an excess of water, decomposition takes place, and a white powder is precipitated, formerly called *powder of Algaroth* (see *Part III.*), which is an oxychloride, having usually the formula $2SbO_3,SbCl_3+HO$. The terchloride is in part decomposed by the water, the elements of which convert it into muriatic acid and teroxide. The muriatic acid remains in solution, while two eqs of teroxide fall in union with one eq. of terchloride, forming the oxychloride of the above formula. The composition of the powder, however, is not uniform; as it contains more teroxide, the greater the proportion of water used in the decomposition. (E. Baudrimont, *Journ. de Pharm.*, Juin, 1856, p. 438.) The oxychloride is first washed with abundance of water to separate adhering muriatic acid, and then acted upon by a solution of alkali (ammonia, *U. S.*, carbonate of soda, *Br.*) to decom-

pose the terchloride, with the effect of adding to the amount of teroxide; after which the teroxide only requires to be washed with water in order to render it pure. The last washing separates the muriate of ammonia or chloride of sodium, resulting from the decomposition of the terchloride; and the water of this washing is tested, in both formulas, by nitrate of silver, until the presence of a chloride ceases to be indicated.

Properties. Teroxide of antimony is a heavy, grayish-white powder, permanent in the air, insoluble in water, but readily soluble in muriatic or tartaric acid, or in a boiling solution of bitartrate of potassa. Heated in close vessels it becomes yellow, fuses at a full red heat, and finally sublimes in crystalline needles. When cooled from a state of fusion it forms a fibrous crystalline mass. Heated in open vessels it suddenly becomes red-hot, and, by the absorption of oxygen, changes into antimonious acid, which differs from the teroxide in being insoluble in muriatic acid, less fusible, and not volatile. This oxide is the active ingredient of all the medicinal preparations of antimony. It is frequently impure from the presence of antimonious acid, in which case it is not *entirely* soluble in muriatic acid. If it contain terchloride, which it is apt to do from the imperfect action of the alkaline solutions employed in its purification, its solution in tartaric acid will be precipitated by nitrate of silver. When antimonious acid is substituted for it, the fraud may be detected by the spurious preparation being entirely insoluble in muriatic acid. Teroxide of antimony consists of one eq. of antimony 129, and three of oxygen 24 = 153.

Medical Properties. This oxide, which must not be confounded with the powder of Algaroth, has the general therapeutic properties of the antimonials. It deserves more attention than has been paid to it; and its effects, comparatively with those of tartar emetic, should be carefully studied. It is probable that its sedative operation would be found to be the same, with less nausea and disturbance of the stomach. Like antimonial powder, it is unequal in its effects, sometimes vomiting, at other times being apparently inert. This inequality of action is plausibly explained by the state of the stomach as to acidity, the presence of acids giving the medicine activity; and this explanation is confirmed by the experiments of Dr. Osborne, of Dublin, with the Dublin oxide. As to the French Codex oxide, prepared by boiling the oxychloride with a solution of bicarbonate of potassa, the inequality is attributed by M. Durand, of Caen, to the presence of more or less terchloride, which is separated with difficulty. Objecting to the Codex oxide, M. Durand proposes to prepare the teroxide by precipitating tartar emetic with ammonia in excess. Thus obtained it contains no terchloride, and does not vomit. (*Journ. de Pharm.*, 3*e sér.*, ii. 364) The dose of teroxide of antimony is three grains, every two or three hours, given in powder with syrup or molasses, or in pill made with confection of roses or other suitable excipient. It was introduced into the existing edition of the U. S. Pharmacopœia, to be used in the preparation of tartar emetic.

ANTIMONII OXYSULPHURETUM. *U. S.* *Oxysulphuret of Antimony. Kermes Mineral.*

"Take of Sulphuret of Antimony, in very fine powder, *a troyounce;* Carbonate of Soda *twenty-three troyounces;* Water *sixteen pints.* Dissolve the Carbonate of Soda in the Water previously heated to the boiling point, and, having added the Sulphuret of Antimony, boil for an hour. Then filter rapidly into a warm earthen vessel, cover this closely, and allow the liquid to cool slowly. At the end of twenty-four hours, decant the supernatant liquid, drain the precipitate on a filter, wash it with boiled water previously allowed to become cold, and dry it without heat. Lastly, preserve the powder in a well-stopped bottle, protected from the light." *U. S.*

Though very long in use as a medicine, and much employed on the Continent of Europe, it was only at the late revision that this preparation was admitted into the U. S. Pharmacopœia, having been superseded by the precipitated sulphuret, which was supposed to have very similar if not identical properties.

Kermes mineral, according to Thenard, may be obtained by treating the tersulphuret of antimony in three ways; 1st with a boiling solution of the carbonated alkalies. 2d with a boiling solution of the caustic alkalies, and 3d with the carbonated alkalies at a red heat. These several processes give brown powders, which vary in their shade of colour, and which, though usually considered as identical, differ in composition. The kermes obtained by means of the carbonated alkalies in solution is an oxysulphuret, that is, a compound of hydrated tersulphuret of antimony with the teroxide; while the product, when either the caustic alkalies in solution, or the carbonated alkalies at a red heat are used, is essentially a hydrated tersulphuret, though containing occasionally a little oxysulphuret. It is the first of these methods that has been adopted in the U. S. process. It is in fact the formula of Cluzel, as published in former editions of the U. S. Dispensatory (see 11 ed. p. 926), and is substantially the same with that given in the French Codex of 1837.

The rationale of the formation of kermes by this process is as follows. A portion of the carbonate of soda is converted, by a transfer of carbonic acid into caustic soda and sesquicarbonate. By a double decomposition taking place between a part of the tersulphuret of antimony and the caustic soda, sulphuret of sodium and teroxide of antimony are formed. The undecomposed portion of the tersulphuret then dissolves in the solution of sulphuret of sodium, and the teroxide in that of the remaining carbonate of soda. The tersulphuret and teroxide, being both more soluble in these menstrua hot than cold, precipitate together as the liquid cools, and constitute this variety of kermes. Thus obtained it is light, velvety, of a dark reddish-purple colour, brilliant in the sun, and of a crystalline appearance. It consists, according to M. Henry, jun., of tersulphuret of antimony 62·5, teroxide 27·4, water 10, and soda a trace; proportions which correspond most nearly with two eqs. of tersulphuret, one of teroxide, and six of water. From the presence of so large a proportion of teroxide of antimony in this variety of kermes, it must be far more active than the other kinds, and ought, therefore, to be preferred for medical use.

Kermes, when obtained by means of the caustic alkalies, may be formed by the use of either potassa or soda. When the former alkali is selected, it may be prepared by boiling, for a quarter of an hour, two parts of the tersulphuret of antimony with one part of caustic potassa dissolved in twenty-five or thirty parts of water, filtering the liquor, and allowing it to cool; whereupon the kermes precipitates. In this process one portion of the tersulphuret, by reacting with a part of the potassa, gives rise to teroxide of antimony and sulphuret of potassium. A second portion dissolves in the solution of sulphuret of potassium formed, and a third forms an insoluble compound with a part of the teroxide. The remainder of the teroxide unites with the undecomposed potassa, forming a compound, which, being but sparingly soluble, is only in part dissolved. The hot filtered liquor, therefore, contains this compound dissolved in water, and tersulphuret of antimony dissolved in the solution of sulphuret of potassium. By refrigeration, the tersulphuret in a hydrated state falls down, free or nearly free from teroxide, this latter being still held in solution by means of the caustic alkali.

Kermes may be obtained by the third method, that is, in the dry way, by the use of the carbonated alkalies at a red heat. If carbonate of potassa is selected, the process is as follows. Rub together two parts of tersulphuret of antimony and one of carbonate of potassa, fuse the mixture in a crucible by a red heat, reduce the fused mass to powder, boil it with water, and strain. As the strained liquor cools the kermes is deposited. The rationale of its formation is nearly the

same with that of the formation of the second variety of kermes. An inferior kermes, prepared in the dry way, and intended for use in veterinary medicine, is directed in the French Codex to be prepared by fusing together, well mixed, 500 parts of tersulphuret of antimony, 1000 of carbonate of potassa, and 30 of washed sulphur, reducing the fused mass to powder, and boiling it with 10,000 parts of water. The liquor, upon cooling, lets fall the kermes, which must be washed with care and dried.

The officinal oxysulphuret is an insipid, inodorous powder, of a purplish-brown colour, and soft and velvety to the touch. By the action of air and light it gradually becomes lighter coloured, and at last yellowish-white. It is readily and wholly dissolved by muriatic acid, with escape of hydrosulphuric acid gas, and is partly soluble in a hot solution of potassa, leaving a residue soluble in tartaric acid. It is sometimes adulterated with sesquioxide of iron. In Paris, in 1849, a number of the shops contained a spurious kermes of very handsome appearance, which was little else than this oxide. Kermes mineral first came into use as a remedy in France about the beginning of the last century. Its mode of preparation was possessed as a secret by a French surgeon named La Ligerie. In 1720, the recipe was purchased by the French government and made public. Its remedial properties will be considered under the following head. B.

ANTIMONIUM SULPHURATUM. *U. S.*, *Br.* Antimonii Sulphuretum Præcipitatum. *U. S.* 1850, *Dub.* Antimonii Oxysulphuretum. *Lond.* Antimonii Sulphuretum Aureum. *Ed.* *Sulphurated Antimony. Precipitated Sulphuret of Antimony.*

"Take of Sulphuret of Antimony, in very fine powder, *six troyounces;* Solution of Potassa *four pints;* Distilled Water, Diluted Sulphuric Acid, each, *a sufficient quantity.* Mix the Sulphuret of Antimony with the Solution of Potassa and twelve pints of Distilled Water, and boil the mixture over a gentle fire for two hours, constantly stirring, and occasionally adding Distilled Water so as to preserve the same measure. Strain the liquid immediately through a double muslin strainer, and drop into it, while yet hot, Diluted Sulphuric Acid so long as it produces a precipitate. Then wash the precipitate with hot water to remove the sulphate of potassa, dry it, and rub it into a fine powder." *U. S.*

"Take of Prepared Sulphuret of Antimony *ten ounces* [avoirdupois]; Solution of Soda *four pints and a half* [Imperial measure]; Diluted Sulphuric Acid, Distilled Water, each, *a sufficiency.* Mix the Sulphuret of Antimony with the Solution of Soda, and boil for two hours with frequent stirring, adding Distilled Water occasionally to maintain the same volume. Strain the liquor through calico, and, before it cools, add to it by degrees the Diluted Sulphuric Acid till the latter is in slight excess. Collect the precipitate on a calico filter, wash with Distilled Water till the washings no longer precipitate with chloride of barium, and dry at a temperature not exceeding 212°." *Br.*

There are three forms of tersulphuret of antimony containing more or less teroxide; the *kermes mineral* already described; the *golden sulphur*, which is produced when, after the spontaneous subsidence of kermes mineral in the process for obtaining it, an acid is added to the liquid; and the *precipitated sulphuret*, which is made by precipitating the liquid before it has begun to deposit the kermes, and may be considered as consisting of the other two combined in one.

Golden sulphur (*sulphur auratum antimonii*) is prepared, according to the French Codex, by precipitating the solution remaining after the deposition of the kermes, in the formula in which one of the caustic alkalies is employed in the first stage of the process, as in the above formula, instead of a carbonate as in the one preceding it. The liquor, when caustic potassa has been used, consists *at first* chiefly of tersulphuret of antimony, dissolved in solution of sulphuret of potassium, but in part also of teroxide, dissolved in solution of potassa. By the action of the

oxygen of the air on the liquor, however, the sulphuret of potassium has part of its potassium gradually converted into potassa, and thus passes to a higher state of sulphuration; and, consequently, the addition of an acid, while it throws down the tersulphuret and teroxide of antimony with disengagement of sulphuretted hydrogen, will separate at the same time the excess of sulphur which the sulphuret of potassium has gained. This excess of sulphur, combining with a portion of the tersulphuret of antimony, produces the pentasulphuret of that metal (*Gmelin*); and the resulting golden sulphur is a mixture of tersulphuret and teroxide of antimony, with more or less of the pentasulphuret. It is in the form of a powder of a golden-yellow colour. As it is partially decomposed by light, it should be kept in opaque vessels. It may be worth while to mention that the so-called *kermes liquor*, left after the use of the carbonated alkalies in solution, gives but little golden sulphur; while the liquors resulting from the two other processes yield it in abundance.

From the explanations above given, the reader is prepared to understand that the method of preparing sulphurated antimony of the U. S. and Br. Pharmacopœias, combines the process for forming kermes mineral by means of a *caustic alkali*, with that for obtaining golden sulphur; for, while the refrigeration of the solution acting alone would cause the precipitation of the variety of kermes, which contains little or no antimonial oxide, the sulphuric acid added would throw down more or less of the golden sulphur. But the question here arises, how far this golden sulphur would be identical with that obtained from the kermes liquor which has been kept for some time. From the explanations above given in relation to golden sulphur, it may be inferred as probable that the precipitate by acids, if thrown down immediately, while the solution is hot, as directed by the Pharmacopœias, and before the air has had time to act, would consist exclusively of tersulphuret and teroxide; but, if thrown down from kermes liquor which had been kept, would contain more or less of the pentasulphuret, according to the length of time which had elapsed. If these views be admitted, it follows that the so-called golden sulphur must be variable as to the pentasulphuret it contains, according to the greater or less change which the kermes liquor may have undergone by time, before being used for furnishing the precipitate.

Formerly, all the Pharmacopœias noticed in this work used a solution of caustic potassa in preparing precipitated sulphuret of antimony; but at present the British Council, following the London College, employs a solution of caustic soda. The use of soda, however, does not alter the theory of the process.

Properties of the Precipitated Sulphuret of Antimony. This substance is a reddish-brown insoluble powder, tasteless when pure, but having usually a slightly styptic taste. When treated with twelve times its weight of muriatic acid of the sp. gr. 1·16, with the aid of heat, it is nearly all dissolved, with effervescence of sulphuretted hydrogen. The residue burns with the characters of sulphur, and leaves a scanty ash. The solution obtained, when added to water, is decomposed, giving rise to a white powder of oxychloride of antimony (powder of Algaroth). The solution, filtered from the powder, yields an orange-red precipitate with bihydrosulphate of ammonia, proving the presence of a portion of antimony, not thrown down by the water. A dark-coloured precipitate, produced by this test, shows the presence of contaminating metals, probably lead and copper. Water in which this preparation has been boiled, should not yield a white precipitate with chloride of barium or oxalate of ammonia. The non-action of these tests shows the absence of sulphuric acid and lime. When pure, precipitated sulphuret of antimony is completely soluble in a hot solution of potassa; but, as it is found in the shops, a white matter is usually left undissolved. When boiled with a solution of cream of tartar, about 12 per cent. of teroxide is dissolved; but, according to H. Rose, this method of determining the proportion of the teroxide cannot be relied on. Exposed to heat it takes fire, and burns

with a greenish-blue flame, giving off sulphurous acid; while the metal remains behind in the state of a grayish oxide.

The London (British) precipitated sulphuret of antimony, as analyzed by Mr. Phillips, consists, in the 100 parts, of tersulphuret 76·5, teroxide 12, and water 11·5; proportions corresponding nearly with five eqs. of tersulphuret, one of teroxide, and fifteen of water. It usually contains a portion of pentasulphuret, as shown by the action of muriatic acid, which, when heated with this antimonial, forms the terchloride with disengagement of sulphur. (*Gmelin's Handbook*, iv. 989.) Its active ingredient is the teroxide; and, in reference to its presence, the London College called the preparation *oxysulphuret of antimony*. The Edinburgh College named it incorrectly *golden sulphuret of antimony;* this name being properly applicable to the precipitate produced by the sole action of acids, and not to that obtained by the action of acids and refrigeration conjointly.

Medical Properties. *Precipitated sulphuret of antimony* is alterative, diaphoretic, and emetic. It is, however, an uncertain medicine, as well from the want of uniformity in its composition, as from its liability to vary in its action with the state of the stomach. It is seldom given alone, but generally in combination with calomel and guaiac, in the form of Plummer's pill, as an alterative in secondary syphilis and cutaneous eruptions, or with henbane or hemlock in chronic rheumatism. (See *Pilulæ Antimonii Compositæ.*) During its use the patient should abstain from acidulous drinks. Its dose as an alterative is from one to two grains twice a day, in the form of pill; as an emetic, from five grains to a scruple.

Kermes mineral, when prepared by means of the carbonated alkalies in the moist way, as it contains between two and three times as much teroxide as the precipitated sulphuret, is a more active preparation, and must be used in a smaller dose. It is sometimes given in large doses as an antiphlogistic remedy in peripneumony and other inflammations of the chest. Prof. Meigs recommends it as an invaluable medicine in childbed fevers, to promote diaphoresis, and to reduce the force of the circulation.

Golden sulphur acts like kermes mineral, but is much weaker, and must be given in a larger dose.

AQUA.

Water.

AQUA DESTILLATA. *U. S., Br. Distilled Water.*

"Take of Water *eighty pints.* Distil two pints, using a tin or glass condenser, and throw them away; then distil sixty-four pints, and keep them in glass bottles." *U. S.*

"Take of Water, free from taste and odour, *ten gallons* [Imperial measure]. Distil from a copper still, connected with a block-tin worm; reject the first half gallon, and preserve the next eight gallons." *Br.*

No natural water is sufficiently pure for certain pharmaceutical purposes; and hence the necessity of the above processes for its distillation. It is best to reject the first portion which comes over, as this may contain carbonic acid and other volatile impurities; and the last portion of the water ought not to be distilled, lest it should pass over with an empyreumatic taste. The distillation is usually performed with the ordinary still and worm; but, to avoid any impurity from the worm or the receiver, the condenser is directed in the U. S. Pharmacopœia to be of tin or glass. In the British formula the worm is ordered to be of block-tin; and the same is undoubtedly contemplated in our officinal process; as the ordinary tin-coated sheet-iron, commonly called tin, would be wholly unfit for the

purpose. Mr. Brande states that distilled water often derives from the still a foreign flavour, which it is difficult to avoid. He, therefore, recommends that a still and condenser be kept exclusively for distilling water; or, where this cannot be done, that steam be driven through the worm for half an hour, for the purpose of washing it out before it is used, the worm-tub having been previously emptied. Mr. Mackay, of Edinburgh, cautions against distilling water in a still with a leaden head or leaden worm, for fear of contaminating the water with lead. Even the use of pure tin, which is generally considered unexceptionable, does not give perfect security against impurity; as water distilled from metallic alembics, with the head and worm of this metal, has a peculiar odour which it retains for some time. A portion of distilled water thus prepared, after having been kept for four months in a well-stopped bottle, was found by M. Flech, an apothecary of Kevelaer, to have deposited white flocculi, which proved on examination to consist of oxidized tin; and the water, besides, contained tin in solution and a little ammonia. M. Flech supposes that a part of the water was decomposed; its oxygen uniting with the tin, and its hydrogen in the nascent state with the nitrogen of the air to form ammonia; and he is disposed, moreover, to ascribe to this cause the peculiar odour referred to, which is never perceived when the distillation is performed in glass vessels. (*Journ. de Pharm.*, Fév. 1860, p. 125.)

Properties, &c. Distilled water, as usually obtained, has a vapid and disagreeable taste, and is not perfectly pure; water, to be rendered so, requiring to be distilled in silver vessels. The properties of pure water have already been given under the head of *Aqua*. Distilled water should undergo no change by sulphuretted hydrogen, or on the addition of tincture of soap, subacetate of lead, chloride of barium, oxalate of ammonia, nitrate of silver, or lime-water, and should evaporate without residue. It is uselessly employed in some formulas, but is essential in others. As a general rule, when small quantities of active medicines are to be given in solution, and in the preparation of collyria, distilled water should be directed. The following list contains the chief substances which require distilled water as a solvent: tartar emetic, corrosive sublimate, nitrate of silver, the chlorides of barium and calcium, acetate and subacetate of lead, permanganate of potassa, the sulphates of iron and zinc, sulphate of quinia, sulphate, muriate, and acetate of morphia, and, in general terms, all the alkaloids and their salts. Distilled water is used in preparing the officinal diluted acids for absorbing gaseous ammonia, and for forming nearly all the officinal aqueous solutions. B.

AQUÆ. *U.S.*

Medicated Waters.

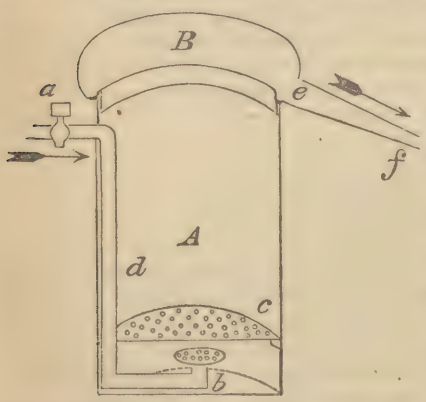
Under this head are included, in the United States Pharmacopœia, all preparations, consisting of water holding volatile or gaseous substances in solution, many of which were formerly obtained by distillation, and some still continue to be so. They include the preparations formerly specially designated as "Distilled Waters," having been made by distilling water from plants or parts of plants containing volatile oil. Distilled water is now placed in the Pharmacopœia under the same head; but we have given it the distinct position which it held in the edition of 1850, and which it might very properly, we think, have continued to hold in the present.

The Distilled Waters, as thus defined, hold a much more prominent position in the pharmacy of Europe, particularly of continental Europe, than in that of the United States; and a great deal of thought and elaborate investigation have been bestowed upon the various conditions calculated to furnish the best products in the most convenient method. It would be doing injustice to the subject not

to give it a distinct consideration in a work like the present, though its relative want of importance with us will render our remarks comparatively brief.

Many vegetables impart to water distilled from them their peculiar flavour, and more or less of their medical properties. The Distilled Waters chiefly used are those prepared from aromatic plants, the volatile oils of which rise with the aqueous vapour, and are condensed with it in the receiver. But, as water is capable of holding but a small proportion of the oil in solution, these preparations are generally feeble, and are employed chiefly as pleasant vehicles or corrigents of other medicines.

In the preparation of the Distilled Waters, dried plants are sometimes used, because the fresh are not to be had at all seasons; but the latter, at least in the instance of herbs and flowers, should be preferred if attainable. Flowers which lose their odour by desiccation may be preserved by incorporating them intimately with one-third of their weight of common salt, and in this state afford Distilled Waters of delicate flavour. Indeed, some pharmaceutists prefer the salted flowers in certain instances, believing that the Waters distilled from them keep better than when prepared from the fresh flowers.



The idea at one time prevailed, to a considerable extent, that Waters kept better distilled from dried herbs than from fresh; and the opinion was true in regard to those prepared with the defective alembics of former times, and by a naked fire; but experiment has sufficiently established the fact, that, with a suitable apparatus, and a regulated heat, the fresh herbs yield products which, while they have a more agreeable odour of the plant, keep quite as well as those from dried herbs. (*Journ. de Pharm.*, Mai, 1861, p. 359.)

It is necessary to observe certain practical rules in conducting the process of distillation. When the substance employed is dry, hard, and fibrous, it should be mechanically divided, and macerated in water for a short time previously to the operation. The quantity of materials should not bear too large a proportion to the capacity of the alembic, as the water might otherwise boil over into the receiver. The water should be brought quickly to the state of ebullition, and continued in that state till the end of the process. Care should be taken to leave sufficient water undistilled to cover the whole of the vegetable matter; lest a portion of the latter, coming in contact with the sides of the vessel, might be decomposed by the heat, and yield empyreumatic products. Besides, when the operation is urged too vigorously, or carried too far, a slimy matter is apt to form, which adheres to the sides of the alembic above the water, and is thus exposed to igneous decomposition. To obviate these disadvantages, the heat may be applied by means of an oil-bath, regulated by a thermometer, or of a bath of solution of chloride of calcium, by which any temperature may be obtained between 212° and 270°, according to the strength of the solution; or, when the process is conducted upon a large scale, by means of steam introduced under pressure into a space around the still. A convenient mode of applying heat by steam, is by means of a coil of leaden tube placed in the bottom of the still, having one end connected with a boiler, and the other passing out beneath or at the side, and furnished with a stop-cock, by which the pressure may be increased, or the condensed water drawn off at will. If any volatile oil float upon the surface of the Distilled Water, it may be separated.*

* This direction is generally given; but, in a communication to the Pharmaceutical Society of England, Mr. Haselden recommends the excess of oil to be well shaken with the water, and the whole to be transferred to the stock vessel, where it may be allowed to rest, and the oil to separate. He thinks the water keeps better when thus treated; and the full strength is always ensured. The stock vessel he prefers made of stone-ware, and furnished with a tap placed two inches from the bottom, whereby the water may be drawn off clear when wanted for the ordinary shop bottles; the oil either rising to the top, or sinking to the bottom of the vessel, according to its specific gravity. (*Pharm. Journ.*, xvi. 14, 15.)—*Note to the eleventh edition.*

From a series of experiments made in Paris in reference to the best mode of applying heat, it was concluded that, as regards the great majority of aromatics, the direct application of steam was preferable, because the Distilled Waters prepared by means of it have a freshness of aroma that is wanting in the others, are always free from the odour of the still, are much more limpid, are less apt to deposit mucilaginous matter, and keep better; but that exceptions to the general rule are afforded by bitter almonds, cherry-laurel leaves, mustard, and horseradish, in all which the oil does not pre-exist in the plant, but is formed upon contact with water, by woods, barks, and roots, the tissue of which cannot be sufficiently penetrated by steam, and by roses. (*Journ. de Pharm.*, Mai. 1861, p. 364.) Later experiments have led to the conclusion that even these substances are most advantageously treated by distillation with steam; and that, in fact, there is no exception to the general rule. All inconvenience and danger in this process are avoided by care to have tubes of large diameter for the supply of the steam, which should be received into a free space reserved, at the bottom of the alembic, by means of a diaphragm pierced with holes. To prevent the loss of vapour, it is sufficient to lute the apparatus by strips of linen or muslin covered with glue or dextrin paste, making two or three turns around the alembic. (*Ibid.*, Juin, 1864, p. 520.)*

But, however carefully the process may be conducted, the Distilled Waters prepared from plants always have at first an unpleasant smoky odour. They may be freed from this by exposure for a short time to the air, before being enclosed in well-stopped bottles, in which they should be preserved. When long kept, they are apt to form a viscid ropy matter, and to become sour. This result has been ascribed to other principles, which rise with the oil in distillation, and promote its decomposition. To prevent this decomposition, the *Edinburgh College* ordered rectified spirit to be added to the water employed in the process of dis-

* Distillation by steam having been demonstrated, in France, to be the best method of preparing the Distilled Waters in all instances, we present, in the margin, the figure of a vertical section of Soubeiran's apparatus for this purpose, somewhat modified. A cylindrical tinned copper or iron boiler (*A*), three and a half feet high and two in diameter, is surmounted by an expanded head or capital (*B*) which is furnished with an inner ledge, forming a kind of gutter, intended to receive the liquid condensed on the inner surface of the capital, and opening into the exit tube (*e*). Across the boiler, about six inches from the bottom, is placed a horizontal septum or diaphragm, pierced with numerous small holes. Through the side of the boiler, near the top, a steam pipe (*a d*), provided with a stop-cock (*a*), enters, and, turning immediately downwards, runs along the side of the boiler to the bottom, where it makes a horizontal bend, and, extending to the middle of the base, turns upwards, and opening by a perforated expansion, like the end of the spout of a watering pot, terminates a little beneath the centre of the diaphragm. The material to be distilled, having been previously properly comminuted, and macerated when necessary, is introduced into the boiler, and rests on the diaphragm. The capital, having then been applied, and secured by a luting of linen bands coated with dextrin paste, steam from any convenient generator is admitted through the tube at its upper extremity, and passing down, escapes through the expanded termination (*b*) beneath the diaphragm, through the small openings of which it passes, and thus penetrates equably all parts of the material. Loaded with the volatile matters, it then rises into the capital, where a portion being condensed falls into the gutter, and the remainder passes out, with the liquid condensed in the capital, through the exit pipe (*f*), whence it enters into a worm or other suitable condensing apparatus.—*Note to the twelfth edition.*

tillation. But this addition is inadequate to the intended object, and is in fact injurious, as the alcohol by long exposure to the air appears to undergo the acetous fermentation. The *London College*, which had previously directed a spirituous addition, abandoned it in the last edition of their Pharmacopœia; and it is not directed in any of the present U. S. or British formulas in which distillation is performed. A better plan is to redistil the Waters. When thus purified, it is said that they may be kept for several years unchanged.

Robiquet considers the mucosity which forms in Distilled Waters as the result of a vegetative process, to which the presence of air is essential. He has found that, so long as the water is covered with a layer of essential oil, it undergoes no change; but that the oil is gradually altered by exposure to the air, and, as soon as it disappears, the water begins to be decomposed. He states that camphor exercises the same preservative influence over the Distilled Waters by resisting the vegetation, and that those in which the odour of camphor is developed keep better on that account. Finally, he has observed that the more Distilled Water is charged with volatile oil, the more abundant is the mucosity when it has begun to form. Robiquet unites with Henry and Guibourt, and with Virey, in recommending that all these Waters, when intended to be kept for a considerable time, should be introduced, immediately after distillation, into bottles of a size proportionate to the probable consumption of the water when brought into use; and that the bottles should be quite filled, and then sealed or otherwise well stopped, so as entirely to exclude the air. It is best that they should be small, and be closed with well-fitting glass stoppers. Thus treated, the Waters may be preserved without change for many years. (*Journ. de Pharm.*, xxi. 402.) If this plan be not put into operation immediately, the Water should, after introduction into the bottle, be heated to about 212° by placing the bottle in boiling water, and, when it begins to run over, should be carefully enclosed.*

Another mode of preparing the Distilled Waters is to substitute the volatile oil, previously separated from the plant, for the plant itself in the process. This mode is directed in the British Pharmacopœia, in several instances. It is said to afford a more permanent product than the preceding; but does not always preserve the flavour of the plant.

In relation to most of the aromatics, the U. S. Pharmacopœia discards altogether the process by distillation, and directs that water should be impregnated with the volatile oil by trituration with carbonate of magnesia, and subsequently filtered. This is by far the most simple and easy process. The resulting solution is pure and permanent, and is perfectly transparent, the carbonate of magnesia being separated by the filtration. Carbonate of magnesia is preferable to the pure earth; as the latter sometimes gives a brownish colour to the liquid, and requires to be used in larger proportion. But both these substances are dissolved in minute quantities, and are apt to occasion a slight flocculent precipitate. They may also possibly prove injurious by decomposing certain substances given in very small doses, as sulphate of morphia, bichloride of mercury, and nitrate of silver. The object of the magnesia or its carbonate is simply to enable the oil to be brought to a state of minute division, and thus presented with a larger surface to the action of the solvent. According to Mr. Robert Warington, this

* It is of some importance to know the proportion which the aromatic submitted to distillation ought to bear to the amount of distilled water obtained. The following statement upon this point, based upon experiments, is contained in the *Journal de Pharmacie* (Mai, 1861, p. 367). Fresh aromatic plants requiring one part of the plant for one of product; wormwood, black cherry, scurvy-grass, hyssop, cherry-laurel, lavender, balm, mint, peach-leaves, roses, and sage;—fresh and dry aromatics requiring one part of the plant to two of product; bitter almonds, orange-flowers, melilot, horseradish, elder, and tansy;—dry and very aromatic plants requiring one part to four of product; angelica, green anise, juniper berries, chamomile, canella, cascarilla, fennel, sassafras, linden flowers, and valerian. —*Note to the twelfth edition.*

object may be better accomplished by porcelain clay, finely powdered glass, or pumice stone, which are wholly insoluble (*Chem. Gaz.*, March, 1845, p. 113); and the London College employed finely powdered silica for the purpose. Chalk and sugar answer the same end; but the latter, by being dissolved with the oil, renders the preparation impure. The *Dublin College* prepared its Waters by agitating an alcoholic solution of the oil with distilled water, and filtering. They consequently contained alcohol, and were liable to the objection, already mentioned, against the medicated waters thus impregnated. They were besides feeble in the properties of their respective oils. In the preparation of the aromatic waters by these processes, it is very important that the water should be pure. The presence of a sulphate causes a decomposition of the oil, resulting in the production of sulphuretted hydrogen and a carbonate; and the aromatic properties are quite lost. (See *Am. Journ. of Pharm.*, xix. 303.) Hence the propriety of the officinal direction to employ distilled water.*

The Distilled Waters are liable to contain various metallic impurities, derived from the vessels in which they are prepared or preserved. The metallic salts which have been found in them are those of iron, zinc, copper, and lead. With ferrocyanide of potassium iron will give a blue colour, zinc and lead white precipitates, and copper a rose-colour followed by chestnut-brown. Sulphuret of sodium causes with the salts of iron, copper, and lead, a brown discoloration more or less deep, followed by precipitates varying from brown to black; with those of zinc, a white precipitate. The Distilled Waters may be freed from these impurities by animal charcoal, previously well purified. The charcoal should be strongly shaken, eight or ten times in the course of a day, with the impure Water, which should then be allowed to rest, and the next day be filtered. Five grains of the charcoal will be sufficient for a gallon of the Distilled Water. (*Journ. de Pharm.*, Nov. 1862, p. 416.) The volatile oils may be recovered from the Waters containing them, or at least may be transferred to a spirituous menstruum, by mixing olive oil with the water, adding a little solution of potassa so as to form a soap, and a consequent emulsion with the liquid, and then neutralizing by an acid. The fixed oil will rise to the surface, bringing the volatile oil along with it. The latter may then be separated from the former by agitation with alcohol. (T. B. Groves, *Pharm. Journ.*, Feb. 1864.) W.

AQUA ACIDI CARBONICI. *U. S. Carbonic Acid Water. Artificial Seltzer Water.*

"By means of a proper apparatus, impregnate Water, contained in a suitable receiver, with a quantity of carbonic acid, equal to five times the bulk of the Water. Carbonic acid may be obtained from Bicarbonate of Soda or from Marble by means of dilute sulphuric acid." *U. S.*

This preparation, which is peculiar to the United States Pharmacopœia, consists of water highly charged with carbonic acid. Water is found to take up its volume of this acid under the pressure of the atmosphere; and Dr. Henry ascer-

* Mr. Haselden prefers the process of distillation from the aromatic itself in the instances of dill, caraway, fennel, cinnamon, and pimento, which are not apt to afford to the distilled water such matter as may cause it to become sour; but he thinks that peppermint, spearmint, and pennyroyal waters may be advantageously prepared by trituration. He advises, however, that these waters should not be filtered, but prepared in quantity, allowed to settle, and drawn off as wanted. (*Pharm. Journ.*, xvi. 14, 15.)—*Note to the eleventh edition.*

Glycerin as a preservative of fresh plants. We have just seen, as this proof was about going to the press, in the *London Pharmaceutical Journal* for October, 1864 (p. 150), a notice by Mr. C. R. C. Tichborne, of Dublin, of a new method of preserving fresh plants for distillation, which promises excellent results. If aromatic flowers are packed in jars with glycerin, their odorous principles are extracted by the glycerin, which, when expressed, affords by distillation Waters in all instances superior to those obtained from the same flowers preserved by means of salt. Mr. Tichborne has thus preserved flowers for two years.—*Note to the twelfth edition.*

tained that precisely the same *volume* of the compressed gas is absorbed under a higher pressure. From this law, the bulk taken up is constant, the quantity being different in proportion as there is more or less driven into a given space. As the space occupied by a gas is inversely as the compressing force, it follows that the quantity of the acid forced into the water will be directly as the pressure. A double pressure will force a double quantity into a given space, and, therefore, cause a double quantity to be absorbed; a treble pressure will drive a treble quantity into the same space, and cause its absorption; and so on for higher pressures, the *bulk* of the *compressed* gas absorbed always remaining the same. From the principles above laid down it follows that, to saturate water with five times its volume of carbonic acid, as directed in the formula, it must be subjected to a pressure of five atmospheres.

Carbonic acid water is familiarly called in this country "*mineral water*," and "*soda water*;" the latter name, originally applied to the preparation when it contained a small portion of carbonate of soda, being from habit continued since the alkali has been omitted. As it is largely consumed both as an agreeable beverage and as a medicine, we give, in a note below, a sketch of an approved apparatus employed in this city for its preparation.*

* The apparatus referred to in the text consists of a strong egg-shaped copper vessel, tinned on the inside, about eighteen inches long, called a generator, fixed upright in a wooden frame, and surmounted by another upright vessel of similar shape, about nine inches long, communicating with the generator by a short neck, and intended to contain the sulphuric acid. Connected with the generator by a copper tube, and placed by its side, is a strong cylindrical vessel for washing the gas, about fifteen inches long and three and a half in diameter, two-thirds filled with water, and to near the bottom of which the connecting tube passes. Severally communicating with the washing vessel are a mercurial gauge to indicate the pressure, and a strong vessel, called the reservoir or fountain, of about the capacity of eighteen gallons, three-fourths filled with water, the connection of the latter being by a lead or gutta percha tube, commanded by a stop-cock. The charge of whiting or marble dust, say eight pounds, and the requisite water are added through an opening in the generator, in front of the sulphuric acid vessel, and closed by a screw stopper. The communication between the acid vessel and generator is commanded by a vertical square rod, reaching within the vessel to about two-thirds of its height, and terminating at its lower end in a screw. This rod, when unscrewed, opens a communication between the acid vessel and the generator. The requisite sulphuric acid is added to the acid vessel through an opening at its top, capable of being closed by a screw stopper. Through the axis of this stopper, and revolving within it, but without having any vertical motion, passes the key, in the lower end of which there is a square hole to fit on the square rod. When the acid vessel is to be closed, the screw stopper, with its key, is placed over the opening, in which situation the lower end of the key reaches down a sufficient distance to embrace loosely the square rod. The stopper is now screwed in, and the key, without revolving with the stopper, descends so as duly to embrace the square rod. By turning the handle of the key in the proper direction, the rod is partially unscrewed, the passage to the generator opened, and the acid gradually flows in. From time to time, when the acid is allowed to enter the generator, its contents are briskly mixed by means of an agitator, attached to a horizontal axis, passing air-tight through the short diameter of the generator, and turned by a crank. The stop-cock between the washing vessel and fountain is now partially opened, and the impregnation of the water with the gas begins. As it proceeds, the sulphuric acid is gradually allowed to enter the generator until it is expended, and the stop-cock is from time to time turned, until it is entirely opened. Finally, after the water is fully charged with gas, and the whiting wholly decomposed, the fountain is detached, and the generator freed from the pulpy sulphate of lime by the assistance of water and the agitator, and its contents allowed to escape through an opening in its most depending part. In the apparatus of the size above described, a single fountain only is charged by one operation, and the carbonic acid water formed contains between nine and ten times its volume of the gas. In this mode of making carbonic acid water, it is perceived that the requisite pressure is obtained by generating the carbonic acid in a confined space.

Numerous other forms of apparatus have been invented for making carbonic acid water. That of Bernhard is figured in the *Am. Journ. of Pharmacy* for Jan. 1856; the figure being taken from *Parrish's Pharmacy*. In this apparatus, the generators and washing vessels are of thickly tinned copper, and the fountains, of cast iron lined with enamel. These fountains are free from objection except for their weight; as also are the stoneware fountains,

Carbonic acid water is dispensed in many of the apothecary shops in this country. The fountain is usually placed in the cellar, and the tube proceeding from the fountain is made to pass through the floor and counter of the shops, and to terminate in a stop-cock, by means of which the carbonic acid water may be drawn off at pleasure. In order to have the liquid cool in summer, the tube from the cellar generally terminates in a strong metallic vessel of convenient shape, placed under the counter and surrounded with ice, and from this vessel a separate tube penetrating the counter proceeds.

Properties. Carbonic acid water is a sparkling liquid, possessing an agreeable, pungent, acidulous taste. It reddens litmus deeply from its state of concentration, and is precipitated by lime-water. Being impregnated with a large quantity of the acid gas under the influence of pressure, it effervesces strongly when freed from restraint. Hence, to preserve its briskness, it should be kept in strong well-corked bottles, placed inverted in a cool place. Several natural waters are of a similar nature; such as those of Seltzer, Spa, and Pyrmont; but the artificial water has the advantage of a stronger impregnation with the acid gas. Carbonic acid water should be made with every precaution to avoid metallic impurity. Hence the necessity of having the fountain well tinned on the inner surface. Even with this precaution, a slight metallic impregnation is not always avoided, especially in the winter season, when the water is less consumed as a drink, and, therefore, allowed to remain longer in the tubes and stop-cocks. Glass fountains are sometimes used with advantage at this season; and a patent has been taken out for a stoneware fountain, enclosed in tinned copper, which is said to answer a good purpose. When leaden tubes are employed to convey the water, it is liable to be contaminated with this metal, which renders it deleterious. A case of colica pictonum was treated by one of the authors, arising from the daily use of the first draught of carbonic acid water from a fountain furnished with tubes of lead. Tubes of pure tin, enclosed in lead ones to give them strength, are free from objection.

Copper fountains, well tinned, are liable to the objections that the tin lining wears away by use, and that there is no convenient means of inspecting their interior, owing to the solder joint, which permanently unites the two sections of the fountain. To remove the latter objection, the improvement has been proposed by Dr. R. O. Doremus, of New York, to have the two sections with flanges, securely bolted together, with intervening gutta-percha packing, in order to furnish facilities for examining the interior, to determine whether re-tinning is necessary. Sometimes drops of solder, and chips of copper are carelessly left in the fountain, and form an additional source of danger. There can be no doubt that carbonic acid water is not unfrequently rendered poisonous by metallic impregnation. Dr. Doremus has proved, by a chemical examination, that lead and copper are sometimes present. (*Am. Journ. of Pharm.*, Sept. 1854, p. 422, from the *Am. Med. Monthly.*) Dr. John T. Plummer, of Richmond, Ind., has found lead. The latter metal is detected by sulphuretted hydrogen, which gives with it a black precipitate, and copper by ferrocyanide of potassium, which causes a brown precipitate. In testing for copper, a few drops of the reagent should be added to a glass of the suspected water, placed on a sheet of white paper; when, if even a minute proportion of copper be present, a brownish discoloration will be seen, upon looking down through the liquid.

Carbonic acid, formerly called *fixed air*, is a colourless gas, of a slightly pungent odour and acid taste. It reddens litmus feebly, and combines with salifiable bases, forming salts called carbonates, from which it is expelled by all the strong

strengthened with iron bands, which are used in Boston. A less costly apparatus than the above is Nichol's patent combination fountain, figured in the same Journal for March, 1856. In this, bicarbonate of soda is used instead of whiting, and the salt is added to the acid, instead of the acid to the salt. For an account of the small apparatus of Mr. R. Knight, which is made of tin and silver exclusively, see the *Pharm. Journal* for May, 1857.

acids. It extinguishes flame, and is quickly fatal to animals when respired. All kinds of fermented liquors which are brisk or sparkling, such as champagne, cider, porter, &c., owe these properties to its presence. Its sp. gr. is 1·52. In 1823 it was liquefied by Faraday by a pressure of 36 atmospheres, and in 1836 solidified by Thilorier, by taking advantage of the cold generated by the sudden gasefaction of the liquid acid, when freed from pressure. It is composed of one eq. of carbon 6, and two of oxygen 16 = 22 (CO_2).

Medical Properties and Uses. Carbonic acid water is diaphoretic, diuretic, and anti-emetic. It forms a grateful drink to febrile patients, allaying thirst, lessening nausea and gastric distress, and promoting the secretion of urine. The quantity taken need only be regulated by the reasonable wishes of the patient. It also forms a very convenient vehicle for the administration of magnesia, the carbonated alkalies, sulphate of magnesia, and the saline cathartics generally; rendering these medicines less unpleasant to the palate, and, in irritable states of the stomach, increasing the chances of their being retained. When used for this purpose, six or eight fluidounces will be sufficient.

Carbonic acid gas was observed to act as a local anæsthetic in ulcerated cancer, so early as 1794, by Dr. John Evart, of Bath. In 1834 it was first used by Prof. Mojon, of Geneva, in dysmenorrhœa, and with the most soothing effect. Since then it has been employed with good effect, in certain painful affections of the uterus, by Prof. Simpson, of Edinburgh, and M. Follin, of Paris. M. Follin, M. Demarquay, and M. Monod have found it particularly useful in relieving the pain in cancer of the uterus and vagina. The first effect of the gas is a sensation of pricking and heat. Another application of carbonic acid by injection is for the production of premature labour. For this purpose it has been successfully employed by Prof. Scanzoni, of Wurzburg, and Prof. Simpson, of Edinburgh. According to Prof. Simpson, the gas is most conveniently generated by mixing, in a bottle, six drachms of crystallized tartaric acid with eight drachms of bicarbonate of soda, dissolved in six fluidounces of water. B.

AQUA AMMONIÆ. *U. S.* Liquor Ammoniæ. *Br., U.S.* 1850. *Water of Ammonia. Solution of Ammonia.*

"Take of Muriate of Ammonia, in small pieces, Lime, each, *twelve troyounces:* Water *six pints;* Distilled Water *a sufficient quantity.* Pour a pint of the Water upon the Lime, in a convenient vessel; and, after it has slaked, stir the mixture so as to bring it to the consistence of a smooth paste. Then add the remainder of the Water, and mix the whole thoroughly together. Decant the milky liquid from the gritty sediment into a glass retort, of the capacity of sixteen pints, and add the Muriate of Ammonia. Place the retort on a sand-bath, and adapt to it a receiver, previously connected with a two-pint bottle, containing a pint of Distilled Water, by means of a glass tube, reaching nearly to the bottom of the bottle. Surround the bottle with ice-cold water; and apply heat, gradually increased, until ammonia ceases to come over. Remove the liquid from the bottle, and add to it sufficient Distilled Water to raise its specific gravity to 0·960. Lastly, keep the liquid in small bottles, well stopped." *U. S.*

"Take of Strong Solution of Ammonia *one pint* [Imperial measure]; Distilled Water *two pints* [Imp. meas.]. Mix, and preserve in a stoppered bottle. Sp. gr. 0·959." *Br.*

The title of this preparation was changed, at the late revision of the U. S. Pharmacopœia, from Liquor Ammoniæ to Aqua Ammoniæ, that it might conform in name as well as character with the Waters, among which all the officinal preparations consisting of aqueous solutions of gaseous bodies are included.

The object of the above processes is to obtain a weak aqueous solution of the alkaline gas ammonia. In the U. S. process, the muriate of ammonia is decomposed by the superior affinity of the lime for its acid, ammonia is disengaged,

and the lime, combining with the acid, forms chloride of calcium and water. The process differs from that of 1850 in introducing the materials into the retort with a large quantity of water, instead of in the dry state. In both cases the gas is driven over by heat, but in the moist plan is accompanied with more watery vapour than in the dry. If the object were to obtain the water of ammonia in the highest possible state of concentration, there might be some advantage in the dry method; but, as a weak solution is contemplated, the wet method is equally efficient, while in all respects more convenient, and productive of better results; for, according to Dr. Squibb, the water of ammonia made by the former officinal process has invariably an empyreumatic odour, from which that made by the present process is free. (*Proceed. of the Am. Pharm. Assoc.*, 1858, p. 407.) The receiver is intended to retain any water holding in solution undecomposed muriate, or the oily matter sometimes contained in the salt, as well as other impurities, which may be driven over by the heat; while the pure gas passes forward into the bottle containing the distilled water, which should not fill it, on account of the increase in the bulk of the water during the absorption of the gas. The tube should extend to near the bottom of the bottle, and pass through a cork, loosely fitting its mouth. To prevent the regurgitation of the water from the bottle into the intermediate vessel, the latter should be furnished with a Welter's safety tube. Large bottles are improper for keeping the water of ammonia; as, when they are partially empty, the atmospheric air within them may furnish a little carbonic acid to the ammonia.

In preparing solution of ammonia, equal weights of muriate of ammonia and lime are used for generating the gaseous ammonia. This proportion gives a great excess of lime, compared with the quantity required if determined by the equivalents; but in practice it is found advantageous to have an excess, as well to ensure the full decomposition of the muriate of ammonia, as to make up for accidental impurities in the lime.

The British Pharmacopœia gives directions for diluting *Liquor Ammoniæ Fortior*, so as to reduce it to the strength of *Liquor Ammoniæ*. This is effected by mixing one measure of the stronger preparation with two measures of distilled water. By dilution to this extent the stronger solution (*Br.*) is brought to the sp. gr. 0·959.

Properties. The properties of Liquor Ammoniæ Fortior have already been given. (See *page* 98.) Those of the officinal solution of ammonia, described in this place, are the same in kind, but weaker in degree. It should be quite free from empyreuma. Its sp. gr. in the U. S. Pharmacopœia is said to be 0·960; in the British, 0·959. When of the density 0·960, 100 grains of it saturate 30 grains of officinal sulphuric acid, and contain nearly 10 grains of ammonia. Of the British preparation "one fluidrachm requires for neutralization 30·8 measures of the *volumetric solution of oxalic acid*." It is incompatible with acids, and with acidulous and many earthy and metallic salts; but it does not decompose the salts of lime, baryta, or strontia, and only partially decomposes those of magnesia. If precipitated by lime-water, the ammonia is partly carbonated. When saturated with nitric acid, it should give no precipitate with carbonate of ammonia, nitrate of silver, or chloride of barium. A precipitate with the first indicates earthy matter; with the second, muriatic acid or a chloride; with the third, sulphuric acid or a sulphate. Commercial solution of ammonia sometimes contains *pyrrol*, *naphthalin*, and other soluble impurities. These may be detected by the solution being reddened by nitric acid, and, after having been supersaturated with muriatic acid, by its tinging a slip of fir wood of a rich purple colour, characteristic of pyrrol. (*Maclagan.*) The source of these impurities is coal-gas liquor, from which the ammoniacal compounds are largely obtained.

Composition. Water is capable of absorbing 670 times its volume of ammoniacal gas at 50°, and increases in bulk about two-thirds. But the officinal solu-

tion of ammonia is by no means a saturated one. Thus, the ammonia contained in the U. S. preparation is about 10 per cent. The following table gives the percentage of ammoniacal gas in aqueous solutions of different densities.

Specific Gravity.	Ammonia per cent.	Specific Gravity.	Ammonia per cent.	Specific Gravity.	Ammonia per cent.
0·8750	32·50	0·9326	17·52	0·9545	11·56
0·8875	29·25	0·9385	15·88	0·9573	10·82
0·9000	26·00	0·9435	14·53	0·9597	10·17

0·9255	19·54				

Medical Properties and Uses. Water of ammonia is stimulant, sudorific, antacid, and rubefacient. It stimulates more particularly the heart and arteries, without unduly exciting the brain. As a stimulant it is occasionally employed in paralysis, hysteria, syncope, asphyxia, and similar affections. In the same complaints it is often applied to the nostrils with advantage; but, in cases of insensibility, care must be taken not to carry the application too far, for fear of inducing dangerous and even fatal bronchitis. As an antacid, it is one of the best remedies in heartburn, and for the relief of sick headache when dependent on gastric acidity. In these cases it acts usefully also by stimulating the stomach. In the bites of poisonous serpents, it has long been deemed a powerful antidote. A case, caused by the bite of a cobra de capello, was successfully treated by Dr. W. Chalmers, formerly of Bengal, in which solution of ammonia was chiefly relied on. A dose of this solution, given in drunkenness, is said to remove the intoxication in a short time. It has been recommended by Dr. Guérard as an application to burns, attended with rubefaction or vesication, in order to relieve the pain and hasten the cure. (*Journ. de Pharm.*, Jan. 1849.) As a rubefacient it is employed united with oils in the form of volatile liniment. (See *Linimentum Ammoniæ.*) The dose is from ten to thirty drops, largely diluted with water to prevent its caustic effect on the mouth and throat. When swallowed in an overdose, its effects are those of a corrosive poison. A case is recorded in the *Journal de Pharmacie* (Avril, 1862, p. 324), in which about three fluidounces were swallowed, with a fatal result in eight days, after great suffering, and various local and systemic disorder. Dissection exhibited signs of inflammation and corrosion of the œsophagus and stomach, with great enlargement and softening of the mesenteric glands and kidneys. The best antidotes are vinegar and lemon juice, which act by neutralizing the ammonia, and must be promptly applied to be useful. The consecutive inflammation must be treated on general principles.

AQUA AMYGDALÆ AMARÆ. *U. S. Bitter Almond Water.*

"Take of Oil of Bitter Almonds *sixteen minims;* Carbonate of Magnesia *sixty grains;* Water *two pints.* Rub the Oil, first with the Carbonate of Magnesia, then with the Water, gradually added, and filter through paper." *U. S.*

This preparation has the effects of hydrocyanic acid on the system, and may be used as a vehicle of other medicines in nervous coughs, and various spasmodic

affections. It is, however, liable to spontaneous change, and is consequently more or less uncertain. A drop of sulphuric acid added to a pint of it will contribute to its preservation; as will also complete exclusion from the light and air. But the better plan is to prepare it in small quantities, as wanted for use. The dose of it, to begin with, when of full strength, should not exceed half a fluidounce. Under the same name, a preparation has been much used on the continent of Europe, prepared by distilling bitter almonds with water. This when fresh is much stronger than the preparation of the U. S. Pharmacopœia, containing, according to an analysis of Geiger, in 1000 parts, 1·2 parts of anhydrous hydrocyanic acid. But, in consequence either of circumstances in the manner of its preparation, or of changes upon being kept, it is of variable and uncertain strength, and cannot be relied on. It has been prescribed with fatal effects; and the greatest caution, therefore, should be observed by the apothecary not to put up the distilled water instead of the officinal.* W.

AQUA ANETHI. *Br. Dill Water.*

"Take of Dill [fruit], bruised, *twenty ounces* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil one gallon." *Br.*

This is seldom if ever used in the United States. W.

AQUA AURANTII FLORUM. *U. S.* Aurantii Aqua. *Br. Orange Flower Water.*

"Take of Orange Flowers *forty-eight troyounces;* Water *sixteen pints.* Mix them, and distil eight pints." *U. S.*

This preparation is placed in the Materia Medica Catalogue of the British Pharmacopœia, as an object of importation. According to this authority, it is obtained indiscriminately from the flowers of the bitter and those of the sweet orange tree; and the same is the case with our own officinal standard; though, in Italy and France, where it is largely made, the flowers of the bitter orange are preferred, as yielding the most fragrant product. It may be prepared in the most Southern districts of our country from the fresh flowers; and these might be brought to the North for the same purpose, if previously incorporated with one-third or one-quarter of their weight of common salt. The proper method is to arrange the flowers and salt in successive layers in jars of stoneware or glass. Notwithstanding, however, the facility of its preparation here, it is generally imported from the South of France, whence it often comes in cans of tinned copper.

Orange flower water is nearly colourless, though usually of a pale yellowish

* In an experiment performed by M. Mayet, one kilogramme (about two avoirdupois pounds) of bitter almond cake from which the fixed oil had been separated, having been finely powdered, and mixed with enough water to form a thin paste, was kept for a day at the temperature of 86° F., and then submitted to distillation by means of steam, with the following results. The products of distillation were collected in separate portions successively, each of 500 grammes (about a pint). The first portion was milky, immediately after distillation, but in two hours became clear, without the separation of oil: the others were limpid from the beginning. The first contained 0·250 per cent. of hydrocyanic acid, the second 0·070 per cent., the third 0·030, and the fourth 0·024 per cent. The mean of these (0·093) exceeded the percentage obtained by testing a mixture of the four in equal parts, which was only 0·088, owing to the necessity, in each examination, of slightly passing the point of saturation before catching with the eye the blue tint that indicates it. M. Mayet thinks, from these premises, that 0·08 per cent., or 80 milligrammes for 100 grammes, would be the proper mean to establish in regulating the strength of the bitter-almond water, if two parts of product are to be obtained from one of the dry material employed. He would, however, prefer stopping the process when one and a half parts had been obtained, in which case a 0·110 per cent. product might be procured, and it would be easy to fix the mean at 0·100 per cent. M. Mayet also satisfied himself that distillation by steam is decidedly preferable in this process to that by the naked fire, provided that *luted coated with dextrin* be employed for luting the apparatus, instead of common paper luting, which does not sufficiently resist steam. (*Journ. de Pharm.*, Juillet, 1861, p. 13.) — *Note to the twelfth edition.*

tint. From being kept in copper bottles, it sometimes contains metallic impurity, which is said to be chiefly carbonate of lead, derived from the lead used as a solder in making the bottles. The means of detecting metallic impurity are mentioned under the general observations on distilled waters, *page* 994. If it contain lead, sulphuretted hydrogen will produce with it a dark precipitate. Much colour, offensive odour, or mouldiness indicates impurity derived from the flowers in distillation.

Orange flower water is used exclusively on account of its agreeable odour, though it may possess slight powers as a nervous stimulant.

W.

AQUA CAMPHORÆ. *U. S., Br. Camphor Water.*

"Take of Camphor *one hundred and twenty grains;* Alcohol *forty minims* Carbonate of Magnesia *half a troyounce;* Distilled Water *two pints.* Rub the Camphor, first with the Alcohol, then with the Carbonate of Magnesia, and lastly with the Water gradually added; then filter through paper." *U. S.*

"Take of Camphor, broken into pieces, *half an ounce* [avoirdupois]; Distilled Water *one gallon* [Imperial measure]. Enclose the camphor in a muslin bag, and attach this to the stopper of a jar containing the Distilled Water. Invert the jar; allow it to stand for at least two days; and pour off the solution when required." *Br.*

In these processes the object is to effect a solution of the camphor. Water is capable of dissolving but a small proportion of this principle; but the quantity varies with the method employed. The present British process is still more inefficient than the old formulas of the different Colleges for their *Mistura Camphoræ*, which has received in the late revision a much more appropriate name. In the *London* process the camphor was first rubbed with a little spirit to powder it, and then with water; in the *Edinburgh*, sugar and almonds were used as an intermedium by which the water might be induced to take up the camphor; in the *Dublin*, the spirit of camphor was shaken with water. All of them produced very weak preparations. In the present British process no trouble is taken even to comminute the camphor, or to shake it with the water, which is thus allowed to take up what it may be disposed to do by contact with the camphor contained in a bag; though some ingenuity is exhibited in retaining the latter, which is lighter than water, beneath the surface of the liquid, by fastening it in a bag to the stopper, and inverting the vessel after introducing the water. The solution thus effected must be extremely feeble, containing probably less than one part in a thousand, which, according to Berzelius, is taken up by water when triturated with camphor. Our own officinal preparation, when properly made, contains about 50 grains to the pint, or more than 3 grains in each fluidounce. (*Journ. of the Phil. Col. of Pharm.*, iv. 13.) Care should be taken to rub all the water, in successive portions, with the mixture of camphor and carbonate of magnesia. The comparative strength of the U. S. preparation is attributable, at least in part, to the minute division effected in the camphor by trituration with the carbonate of magnesia, which is afterwards separated by filtration. The use of the alcohol is simply to break down the cohesion of the camphor, and enable it to be more easily pulverized. This process is much preferable to the British, as it affords a permanent solution, of sufficient strength to be employed with a view to the influence of the camphor on the system; while the other has little more than the flavour of the narcotic, and is fit only for a vehicle of other medicines. The camphor is separated by a solution of pure potassa, and, according to Dr. Paris, by sulphate of magnesia and several other salts. Sir J. Murray proposes a solution of camphor and bicarbonate of magnesia, which contains three grains of the former and six grains of the latter in each fluidounce.

Camphor water is employed chiefly in low fevers and typhoid diseases, at-

tended with restlessness, slight delirium, or other symptoms of nervous derangement or debility. It is used also to allay uterine after-pains. It has this advantage over camphor in substance, that the latter is with difficulty dissolved by the liquors of the stomach; but it is not applicable to cases where very large doses of the medicine are required. It is usually given in the dose of one or two tablespoonfuls repeated every hour or two hours. W.

AQUA CARUI. *Br. Caraway Water.*

"Take of Caraway, bruised, *twenty ounces* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil one gallon [Imp. meas.]." *Br.*

Distilled caraway water has the flavour and pungency of the seeds, but is seldom used in this country. The preparation employed here is usually made from the volatile oil, in the same manner as cinnamon water. (See *Aqua Cinnamomi.*) W.

AQUA CHLORINII. *U. S.* LIQUOR CHLORI. *Br. Chlorine Water. Solution of Chlorine.*

"Take of Black Oxide of Manganese, in fine powder, *half a troyounce;* Muriatic Acid *three troyounces;* Water *four fluidounces;* Distilled Water *twenty fluidounces.* Introduce the Oxide into a flask, add the Acid previously diluted with two fluidounces of the Water, and apply a gentle heat. Conduct the generated chlorine, by suitable tubes, through the remainder of the Water contained in a small intermediate vessel, to the bottom of a four-pint bottle containing the Distilled Water, and loosely stopped with cotton. When the air has been entirely displaced by the gas, disconnect the bottle from the apparatus, and, having inserted the stopper, agitate the contents, loosening the stopper from time to time, until the gas ceases to be absorbed. Lastly, pour the Chlorine Water into a bottle, of just sufficient capacity to hold it, stop it securely, and keep it in a cool place, protected from the light." *U. S.*

"Take of Hydrochloric Acid *six fluidounces* [Imperial measure]; Black Oxide of Manganese, in fine powder, *one ounce* [avoirdupois]; Distilled Water *thirty-four fluidounces* [Imp. meas.]. Introduce the Oxide of Manganese into a gas-bottle, and, having poured upon it the Hydrochloric Acid diluted with two [fluid]ounces of the Water, apply a gentle heat, and, by suitable tubes, cause the gas, as it is developed, to pass through two [fluid]ounces of the Water placed in an intermediate small phial, and thence to the bottom of a three-pint bottle containing the remainder of the Water, the mouth of which is loosely plugged with tow. As soon as the chlorine ceases to be developed, let the bottle be disconnected from the apparatus in which the gas has been generated, corked loosely, and shaken until the chlorine is absorbed. Lastly, introduce the solution into a green glass bottle furnished with a well-fitting stopper, and keep it in a cool and dark place." *Br.*

The U. S. and Br. processes are essentially the same; and both were copied from the late Dublin process. The only material variation in the British formula is the somewhat larger proportion of the black oxide of manganese and muriatic acid, to the distilled water; an avoirdupois ounce of the oxide and six fluidounces of the acid having been substituted for half the quantity of each as directed by the Dublin College, while the distilled water used by the former is only thirty-four fluidounces to twenty-four by the latter, of which quantities four fluidounces are taken by each in the preliminary steps of the process, and the remainder used for the absorption of the chlorine. In the U. S. formula, the proportions differ from those of the Dublin, in the use of the troyounce both for the oxide of manganese and the acid, instead of the avoirdupois ounce for the former and the fluidounce for the latter. The British process differs from both in directing the disconnection of the apparatus for generating the gas, as soon as it ceases to be produced, instead of after the air in the receiving bottle has been displaced by it. Should there be any danger of deficiency of chlorine in

the resulting chlorine water, the British process would have the advantage, as it uses not only a larger proportion of the materials for making the gas, but exhausts them.

In the U. S. process, four fluidounces of common water are used in the dilution of the muriatic acid, and for absorbing the impurities in the intermediate vial. The twenty fluidounces of distilled water are placed in a four-pint bottle, which it about one-third fills. In both processes, the chlorine gas is extricated from the muriatic acid by the deutoxide of manganese separating the hydrogen, and is passed, through an intermediate vessel containing a little water for purifying it, into the four-pint bottle, loosely stopped, until the vacant part of the bottle is filled with it to the exclusion of the atmospheric air. The bottle being then corked, is shaken so as to cause the absorption of the gas by the water. Of course the stopper must be from time to time loosened, in order to allow the entrance of air to supply the partial vacuum created by the absorption of the chlorine. The product is about a pint and a quarter of the chlorine water, which is transferred to a bottle just sufficient in capacity to hold it. The chlorine water is directed to be kept secluded from the light, because otherwise it would be apt to be converted partially into muriatic acid, through the union of the chlorine with the hydrogen of the water. In the Br. Pharmacopœia it is ordered to be kept in a green glass bottle, for the purpose, probably, of protecting it from the light; but recent experiments have shown that it is an orange, and not a green colour, which appears to prevent the passage of the chemical rays.

Properties. Chlorine water has a pale yellowish-green colour, an astringent taste, and the peculiar odour of the gas. Like gaseous chlorine it destroys vegetable colours. When cooled to about the freezing point, it forms deep-yellow crystalline plates, consisting of hydrate of chlorine. It is intended to contain at least twice its volume of the gas. It is decomposed by light, with the production of muriatic acid, and the evolution of oxygen, and hence must be kept in a dark place. According to MM. Riegel and Walz, chlorine water, containing two and a half volumes of the gas at 54°, keeps best. The U. S. Pharmacopœia gives as a test of its strength in chlorine, that "when a fluidounce of it is mixed with a solution of 10 grains of pure sulphate of protoxide of iron in two fluidrachms of water, the mixture does not produce a blue precipitate with ferridcyanide of potassium (red prussiate of potassa)." This shows that there is sufficient chlorine in the Water to peroxidize the protoxide of iron of the protosulphate; as, though the protosalts of iron do, the persalts do not produce a blue precipitate with the ferridcyanide. The British solution consists of "chlorine gas dissolved in half its volume of water, and constituting 0·006 of the weight of the solution. It immediately discharges the blue colour of a dilute solution of indigo. Its sp. gr. is 1·003, and when evaporated it leaves no residue. When 20 grains of iodide of potassium, dissolved in a [fluid]ounce of distilled water, are added to a fluidounce of this preparation, the mixed solution acquires a deep-red colour, which requires for its discharge 75 measures of the *volumetric solution of the hyposulphite of soda.*" This indicates the quantity of chlorine in the solution, by the amount of the hyposulphite required to decolorize an equivalent quantity of iodine, liberated from the iodide of potassium.

Chlorine is an elementary gaseous fluid, of a greenish-yellow colour, and characteristic smell and taste. It is a supporter of combustion. Its specific gravity is 2·47, and equivalent number 35·5. When the attempt is made to breathe it, even much diluted, it excites cough and a sense of suffocation, and causes a discharge from the mucous membrane of the nostrils and bronchial tubes. Breathed in considerable quantities, it produces spitting of blood, violent pains, and sometimes death.

Medical Properties and Uses. Chlorine water is stimulant and antiseptic. Internally it has been used in typhus, and chronic affections of the liver; but

the diseases in which it has been most extolled are scarlatina and malignant sorethroat. Externally it is employed, duly diluted, as a gargle in smallpox, scarlatina, and putrid sorethroat, as a wash for ill-conditioned ulcers and cancerous sores, and as a local bath in diseases of the liver. It has been used with advantage as an application to buboes and large abscesses, to promote the absorption of the matter. As it depends upon chlorine for its activity, its medical properties coincide with those of chlorinated lime, chlorinated soda, and nitromuriatic acid, under which heads they are more particularly given. The dose of chlorine water is from one to four fluidrachms, properly diluted.

Gaseous chlorine has been recommended by Gannal in chronic bronchitis and pulmonary consumption, exhibited by inhalation, in minute quantities, four or six times a day. Its first effect is to produce some dryness of the fauces, with increased expectoration for a time, followed ultimately with diminution of the sputa and amendment. Dr. Christison states that he has repeatedly observed these results in chronic catarrh; and both he and Dr. Elliotson have obtained, in consumption, a more decided improvement of the symptoms by the use of chlorine inhalations than by any other means. The liquid in the inhaler may be formed either of water containing from ten to thirty drops of chlorine water, or of chlorinated lime dissolved in forty parts of water, to which a drop or two of sulphuric acid must be added, each time the inhalation is practised. The inhaler should be placed in water, heated to about 100° B.

AQUA CINNAMOMI. *U. S., Br. Cinnamon Water.*

"Take of Oil of Cinnamon *half a fluidrachm;* Carbonate of Magnesia *sixty grains;* Distilled Water *two pints.* Rub the Oil first with the Carbonate of Magnesia, then with the Water, gradually added, and filter through paper.

"Cinnamon Water may also be prepared by mixing *eighteen troyounces* of Cinnamon, in coarse powder, with *sixteen pints* of Water, and distilling eight pints." *U. S.*

"Take of Cinnamon, bruised, *twenty ounces* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil a gallon." *Br.*

Of these processes, the first one of the U. S. Pharmacopœia is the easier, though the second, which corresponds with the British, may yield a sweeter product. Cinnamon water is much used as a vehicle for other less agreeable medicines; but should be given cautiously in inflammatory affections. For ordinary purposes the U. S. preparation is sufficiently strong when diluted with an equal measure of water.

Off. Prep. Mistura Cretæ; Mistura Guaiaci, *Br.* W.

AQUA CREASOTI. *U. S. Creasote Water.*

"Take of Creasote *a fluidrachm;* Distilled Water *a pint.* Mix them, and agitate the mixture until the Creasote is dissolved." *U. S.*

This preparation contains 3·72 minims of creasote in each fluidounce, and affords a convenient method of administering that medicine. The dose is from one to four fluidrachms. It may also be used with advantage as a gargle, lotion, or mixed with cataplasms, to correct fetor, and gently stimulate indolent surfaces. W.

AQUA FŒNICULI. *U. S., Br. Fennel Water.*

"Take of Oil of Fennel *half a fluidrachm;* Carbonate of Magnesia *sixty grains;* Distilled Water *two pints.* Rub the Oil first with the Carbonate of Magnesia, then with the Water, gradually added, and filter through paper.

"Fennel Water may be prepared by mixing *eighteen troyounces* of Fennel, in coarse powder, with *sixteen pints* of Water, and distilling eight pints." *U. S.*

"Take of Sweet Fennel Fruit, bruised, *twenty ounces* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil one gallon." *Br.*

Fennel water is an agreeable vehicle for other medicines, and useful when a mild aromatic is indicated. W.

AQUA LAURO-CERASI. *Br. Cherry-laurel Water.*

"Take of Fresh Leaves of Common Laurel [cherry-laurel] *one pound* [avoirdupois]; Water *two pints and a half* [Imperial measure]. Chop the Leaves, crush them in a mortar, and macerate them in the Water for twenty-four hours. Distil one pint [Imp. meas.] of liquid, using a chloride of zinc bath and a Liebig's condenser; shake the product, filter through paper, and preserve in a stoppered bottle." *Br.*

As the cherry-laurel is little cultivated in the United States, we have no officinal formula for the Water; but, from experiments by Prof. Procter, there is little or no room to doubt that a preparation, identical in its effects, might be made from the leaves of our common wild cherry, *Cerasus Serotina*, were a demand for the medicine to spring up among us. The imported cherry-laurel water, as found in our shops, is generally more or less impaired by age, and cannot, therefore, be relied on.

The leaves yield a larger product of hydrocyanic acid when cut and bruised than when distilled whole. According to M. Garot, the proportion of the acid in cherry-laurel water depends upon the time of year at which the distillation is performed; the leaves yielding not more than half as much in April as in the middle of July. (*Annuaire de Thérap.*, 1843, p. 45.) In preparing this water, the best plan is to thoroughly bruise the leaves, and, having mixed them with at least three times their weight of water, to allow the mixture to stand at a temperature of about 86° F. for at least twelve hours, so that opportunity may be given for those reactions by which the hydrocyanic acid is produced, and then to distil them by means of a current of steam. Without the preliminary maceration the distillation by steam does not afford a satisfactory result; but properly performed, it yields the largest possible product. (*Journ. de Pharm.*, Juillet, 1861, p. 15; and Juin, 1864, p. 523.) The proportion of hydrocyanic acid in the water diminishes with time. It has been ascertained by M. Deschamps that, if a drop of sulphuric acid be added to a pint of the preparation, it will keep unchanged for at least a year. It is best preserved by the entire exclusion of air and light. M. Lepage found that, preserved in full and perfectly air-tight bottles, both this and bitter almond water remained unchanged at the end of a year; while, if freely exposed to the air, they lost all their hydrocyanic acid and essential oil in two or three months. (*Ibid.*, xvi. 346.) In view of the uncertain strength of the Water as obtained from the leaves, it is proposed in France, in reference to the forthcoming Codex, to fix upon a definite proportion of hydrocyanic acid; and the percentage generally adopted is from 0·04 to 0·05.* Cherry-laurel water is employed in Europe as a sedative narcotic, identical in its pro-

* The following conclusions, in reference to Cherry-laurel water, have been arrived at by a committee of pharmaceutists in Paris, appointed to examine the subject of the distilled water with a view to the revision of the Codex. 1. The whole of the volatile oil and hydrocyanic acid furnished *by* cherry-laurel leaves, results from a reaction between two substances analogous to the emulsin and amygdalin of bitter almonds, which can take place only in the presence of water. 2. The quantity of volatile oil furnished by the leaves is always in direct relation to that of hydrocyanic acid. 3. The leaves furnish, by mere contact for 24 hours with cold water, only one-third of the quantity which they can be made to yield. 4. The fermentable matter of the leaves is liable to change, so that the leaves, after being picked, afford less and less of the acid the longer they are kept; and a moist heat favours change; so that complete decomposition takes place in a few hours. 5. Difference in climate, soil, exposure to the sun, and age of the tree, have but a secondary influence on the productiveness of the leaves. 6. The season of the year, however, has a great influence. The younger the leaf, the greater is its yield: so that, while 0·150 per cent. of the acid was obtained from the forming leaves in spring, those of the autumn yielded 0·132, and those of the winter 0·120, while leaves two years old gave only 0·112. 7. Different plants, under apparently the same circumstances, differ greatly in productive-

perties with a dilute solution of hydrocyanic acid; but it is of uncertain strength, and should not be allowed to supersede the more definite preparation of the acid now in use. The dose is from thirty minims to a fluidrachm. W.

AQUA MENTHÆ PIPERITÆ. *U. S., Br. Peppermint Water.*

Take of Oil of Peppermint *half a fluidrachm;* Carbonate of Magnesia *sixty grains;* Distilled Water *two pints.* Rub the Oil, first with the Carbonate of Magnesia, then with the Water, gradually added, and filter through paper.

"Peppermint Water may also be prepared by mixing *eighteen troyounces* of Peppermint with *sixteen pints* of Water, and distilling eight pints." *U. S.*

"Take of English Oil of Peppermint *one fluidrachm and a half;* Water *one gallon and a half* [Imperial measure]. Distil one gallon." *Br.* W.

AQUA MENTHÆ VIRIDIS. *U. S., Br. Spearmint Water.*

Both in the U. S. and Br. Pharmacopœias, this is prepared precisely as Peppermint Water, the oil and herb of M. viridis being substituted in the processes for those of M. piperita.

The two mint waters are among the most grateful and most employed of this class of preparations. Together with cinnamon water, they are used in this country, almost to the exclusion of all others, as the vehicle of medicines given in the form of mixture. They serve not only to conceal or qualify the taste of other medicines, but also to counteract their nauseating properties. Peppermint water is generally thought to have a more agreeable flavour than that of spearmint, but some prefer the latter. Their effects are the same. W.

AQUA PIMENTÆ. *Br. Pimento Water.*

"Take of Pimento, bruised, *fourteen ounces* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil one gallon [Imp. meas.]." *Br.*

Pimento water is brownish when first distilled, and upon standing deposits a brown resinous sediment. It is used as a carminative in the dose of one or two fluidounces. W.

AQUA ROSÆ. *U. S., Br. Rose Water.*

"Take of Pale Rose *forty-eight troyounces;* Water *sixteen pints.* Mix them and distil eight pints.

"When it is desirable to keep the Rose for some time before distilling, it may be preserved by being well mixed with half its weight of Chloride of Sodium." *U. S.*

"Take of Fresh Petals of the Hundred-leaved Rose *ten pounds* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil one gallon [Imp. meas.]." *Br.*

It should be observed that, in the nomenclature of the U. S. Pharmacopœia,

ness, so that 0·176 per cent. was obtained from the most productive, only 0·092 from the least so. 8. The distillation by steam yields the greatest possible product. The committee, therefore, propose the adoption of this method; the bruised leaves being preliminarily mixed with at least three times their weight of water, and exposed to a gradually increasing heat, not to exceed 140° F., when all reaction ceases. 9. Bruising is the best method of comminuting the leaves. 10. As it is impossible to obtain a Water always identical from the leaves, the committee propose to fix a definite strength, and state that the proportion generally adopted is from 0·040 per cent. of acid as the minimum, to 0·050, or one-twentieth of one per cent. as the maximum, which is only one-half the strength proposed for bitter-almond water. 11. Though a change rapidly takes place in this and bitter-almond water exposed to the air, yet in bottles full, and perfectly closed by glass stoppers, the change at the end of a year is scarcely perceptible; and this observation applies to the distilled waters in general. (*Journ. de Pharm.*, Juin, 1864, p. 520.)

For some remarks as to an easy volumetric method of estimating the hydrocyanic acid strength of cherry-laurel and bitter-almond waters, as well as other liquids containing this acid, together with the figure of a simple instrument for the purpose, see a paper by Dr. W. H. Pile, in the *American Journal of Pharmacy*, March, 1862, p. 130.—*Note to the twelfth edition.*

the term "Rose" implies only the petals of the flower. These are usually preferred in the recent state; but it is said that, when preserved by being incorporated with one-third of their weight of common salt, they retain their odour, and afford a water equally fragrant with that prepared from the fresh flower. Indeed, Mr. Haselden prefers the salted roses, believing that the water prepared from them is less mucilaginous, less apt to become sour, and preserves its odour better than that prepared from the fresh flowers. (*Pharm. Journ.*, xvi. 15.) Hence the direction for preserving them in the present U. S. Pharmacopœia. It is not uncommon to employ the whole flower including the calyx; but the product is less fragrant than when the petals only are used, as officinally directed.* Rose water is sometimes made by distilling together water and the oil of roses.

When properly prepared, it has the delightful perfume of the rose in great perfection. It is most successfully made on a large scale. Like the other distilled waters it is liable to spoil when kept; and the alcohol which is sometimes added to preserve it is incompatible with some of the purposes to which the water is applied, and is even said to render it sour through acetous fermentation. It is best, therefore, to avoid this addition, and to substitute a second distillation. This distilled water is chiefly employed, on account of its agreeable odour, in collyria and other lotions. It is wholly destitute of irritating properties, unless when it contains alcohol.†

Off. Prep. Confectio Rosæ, *U. S.;* Mistura Ferri Composita; Unguentum Aquæ Rosæ, *U. S.* W

AQUA SAMBUCI. *Br. Elder-flower Water.*

"Take of Fresh Elder Flowers, separated from the stalks, *ten pounds* [avoirdupois]; Water *two gallons* [Imperial measure]. Distil one gallon [Imp. meas.]." *Br.*

Elder flowers yield very little oil upon distillation; and, if the water be needed, it may be best prepared from the flowers. Mr. Haselden prefers the salted flowers to the fresh, for the reason stated above under Rose Water. The preparation is little used in this country. W.

ARGENTUM.

Preparations of Silver.

ARGENTI CYANIDUM. *U. S.* Argenti Cyanuretum. *U.S.* 1850. *Cyanide of Silver. Cyanuret of Silver.*

"Take of Nitrate of Silver, Ferrocyanide of Potassium, each, *two troyounces;* Sulphuric Acid *a troyounce and a half;* Distilled Water *a sufficient quantity.* Dissolve the Nitrate of Silver in a pint of Distilled Water, and pour the solution into a tubulated glass receiver. Dissolve the Ferrocyanide of Potassium in ten fluidounces of Distilled Water, and pour the solution into a tubulated retort, previously adapted to the receiver. Having mixed the Sulphuric

* A. Monthus states that the petals of the hundred-leaved rose are more odorous, the nearer they are to the centre of the flower, and, contrary to what is said in the text, thinks that the calyx should not be rejected in preparing the distilled water. He maintains that, so far from injuring the product, it in fact contributes to its preservation, and that the water obtained from the whole flower is less liable to that mucosity, which is the commencement of decomposition. This effect he ascribes to the astringent matter of the calyx, which coagulates the mucilaginous matter of the petals, and thus prevents it from passing over in the distillation. (*Journ. de Pharm.*, Dec. 1863, p. 497.)—*Note to the twelfth edition.*

† *Artificial Rose Water.* Prof. Wagner, of Germany, prepares a distilled water from the *oil of gaultheria*, with an odour so closely resembling that of the rose as to be entitled to this designation. He boils the oil with solution of potassa, thereby obtaining salicylate of potassa, the mother liquor of which, when distilled with water, yields the preparation in question. (*Chem. Gaz.*, No 382, p. 352, from *Wagner's Jahresbericht*, A. D. 1856, p. 260.)—*Note to the twelfth edition.*

Acid with four fluidounces of Distilled Water, add the mixture to the solution in the retort, and distil, by means of a sand-bath, with a moderate heat, until six fluidounces have passed over, or until the distillate no longer produces a precipitate in the receiver. Lastly, wash the precipitate with Distilled Water, and dry it." *U. S.*

This preparation was introduced into the U. S. Pharmacopœia for the purpose of being used in the extemporaneous preparation of diluted hydrocyanic acid. (See *page* 923.) By the formula adopted in the Pharmacopœia of 1840, the officinal hydrocyanic acid was added to a solution of nitrate of silver. The expenditure in this way of the officinal acid, which is very weak, and at the same time nicely adjusted to a given strength, was injudiciously directed; and, accordingly, that formula was abandoned, and a new process adopted in the Pharmacopœia of 1850, and continued in the present, in which all the silver contained in a given weight of nitrate of silver, placed in a receiver in solution, is converted into cyanide by hydrocyanic acid, extricated from ferrocyanide of potassium by the action of sulphuric acid. By a double decomposition between the oxide of silver of the nitrate and the hydrocyanic acid, water and cyanide of silver are formed in the receiver, the latter of which precipitates. The materials in the retort are sufficient to produce a little more hydrocyanic acid than is necessary to convert the whole of the silver in the receiver into cyanide; so that the complete decomposition of the nitrate of silver is ensured.

According to Messrs. Glassford and Napier, the best way of obtaining cyanide of silver is to add cyanide of potassium to a solution of nitrate of silver so long as a precipitate is formed.

Properties. Cyanide of silver is a tasteless white powder, insoluble in water and cold nitric acid, but readily soluble, with decomposition, in that acid when boiling hot. It is decomposed by muriatic acid, exhaling the odour of hydrocyanic acid. It is not soluble in potassa or soda, but readily so in ammonia. Its best solvent is cyanide of potassium. When heated it is decomposed, cyanogen being evolved, and metallic silver left. It consists of one eq. of cyanogen 26, and one of silver 108 = 134. It has no medical uses.

Off. Prep. Acidum Hydrocyanicum Dilutum, *U. S.* B.

ARGENTI NITRAS. *U. S.*, *Br.* *Nitrate of Silver. Nitrate of Silver in Crystals.*

"Take of Silver, in small pieces, *two troyounces;* Nitric Acid *two troyounces and a half;* Distilled Water *a sufficient quantity.* Mix the Acid with a fluidounce of Distilled Water in a porcelain capsule, add the Silver to the mixture, cover it with an inverted glass funnel, resting within the edge of the capsule, and apply a gentle heat until the metal is dissolved, and red vapours cease to be produced; then remove the funnel, and, increasing the heat, evaporate the solution to dryness. Melt the dry mass, and continue the heat, stirring constantly with a glass rod, until free nitric acid is entirely dissipated. Dissolve the melted salt, when cold, in six fluidounces of Distilled Water, allow the insoluble matter to subside, and decant the clear solution. Mix the residue with a fluidounce of Distilled Water, filter through paper, and, having added the filtrate to the decanted solution, evaporate the liquid until a pellicle begins to form, and set it aside in a warm place to crystallize. Lastly, drain the crystals in a glass funnel until dry, and preserve them in a well-stopped bottle. By evaporating the mother-water, more crystals may be obtained." *U. S.*

"Take of Refined Silver *three ounces* [avoirdupois]; Nitric Acid *one fluidounce and three-quarters* [Imperial measure]; Distilled Water *five fluidounces* [Imp. meas.]. Add the Nitric Acid and the Water to the Silver in a flask, and apply a gentle heat till the metal is dissolved. Decant the clear liquor from any black powder which may be present, into a porcelain dish, evaporate, and set aside to crystallize. Let the crystals drain in a glass funnel, and dry them by

exposure to the air, carefully avoiding the contact of all organic substances Nitrate of Silver must be preserved in bottles furnished with accurately ground stoppers." *Br.*

The two formulas are essentially the same; but that of the U. S. Pharmacopœia is more detailed and precise, with two peculiarities which deserve notice. One of these is the direction to cover the materials in the capsule, during the continuance of the reaction, with a glass funnel. This is in order to economize the nitric acid, a portion of which rises in vapour, and, being condensed on the inner surface of the funnel, falls again into the capsule. The second peculiarity is the fusion of the salt before being dissolved. This would, from the phraseology of the directions, appear to have been intended to get rid of any uncombined nitric acid which might remain in the dry salt. But the effect is probably rather to decompose any nitrate of copper that might have been derived from the silver, which, if coin be employed, always contains it. This accounts for the escape of hyponitric acid vapour. The oxide of copper is got rid of in the subsequent solution.

During the solution of silver in nitric acid, part of the acid is decomposed into nitric oxide which is given off and becomes red fumes by contact with the atmosphere, and oxygen which oxidizes the silver. The oxide formed then combines with the remainder of the acid, and generates the nitrate of silver in solution, which, by due evaporation, furnishes crystals of the salt. The silver should be pure, and the acid diluted for the purpose of promoting its action. If the silver contain copper, the solution will have a greenish tint, not disappearing on the application of heat; and if a minute portion of gold be present, it will be left undissolved as a black powder. The acid also should be pure. The commercial nitric acid, as it frequently contains both muriatic and sulphuric acids, should never be used in this process. The muriatic acid gives rise to an insoluble chloride, and the sulphuric, to the sparingly soluble sulphate of silver.*

Properties. Nitrate of silver is in colourless transparent shining crystals, having the form of rhomboidal plates, sometimes of considerable size. Its taste is bitter and intensely metallic. It is soluble in its own weight of cold water, and in four parts of boiling alcohol. When perfectly pure, it is wholly soluble in distilled water. The solution stains the skin of an indelible black colour, and is itself discoloured by the most minute portion of organic matter, of which it forms a delicate test. The affinity of this salt for animal matter is evinced by its forming definite compounds with albumen and fibrin. The solution also stains linen and muslin in a similar manner; and hence its use in making the so-called indelible ink. To remove these stains, Mr. W. B. Herapath advises to let fall on the moistened spots a few drops of tincture of iodine, which converts the silver into iodide of silver. The iodide is then dissolved by a solution of hyposulphite of soda, made with half a drachm to a fluidounce of water, or by a moderately dilute solution of caustic potassa, and the spots are washed out with warm water. They are taken out also by a solution of two and a half drachms of cyanide of potassium, and fifteen grains of iodine, in three fluidounces of water. Stains on the skin may be removed by the same reagents. Nitrate of silver melts at 426°, and on concreting forms the fused nitrate, which is officinal under the name of *Argenti Nitras Fusa.* At about 600° it is decomposed, with evolution of oxygen and hyponitric acid, and the metal is revived. This explains the necessity of

* It is desirable that pure silver, free from copper, should be used in this process. As silver coin always contains copper, it should be purified before being employed. For this purpose, according to the method of M. Lienau, it should be dissolved in nitric acid, and the solution precipitated by chlorine water, which throws down the silver only in the form of chloride. The precipitate is to be well washed with chlorine water, then dissolved in solution of ammonia, and precipitated by clean copper wire. The silver is deposited as a black powder, which when washed with solution of ammonia, is perfectly pure. (See *Am. Journ. of Pharm.*, July, 1862, p. 368.)

guarding against too high a heat during the fusion of the salt. Nitrate of silver is incompatible with almost all spring and river water, on account of a little common salt usually contained in it; with soluble chlorides; with sulphuric, hydrosulphuric, muriatic, and tartaric acids, and their salts; with the alkalies and their carbonates; with lime-water; and with astringent infusions. It is sometimes improperly prescribed in pill with tannic acid, by which it is decomposed. Nitrate of silver is an anhydrous salt, consisting of one eq. of nitric acid 54, and one of protoxide of silver 116 = 170 (AgO,NO_5).

Impurities and Tests. Muriatic acid or a solution of chloride of sodium, added in excess to one of nitrate of silver, should throw down the whole of the silver as a white curdy precipitate darkening on exposure to light, and nothing besides. This precipitate should be entirely soluble in ammonia. If not so, the insoluble part is probably chloride of lead. If the supernatant liquid, after the removal of the precipitate, be discoloured or precipitated by sulphuretted hydrogen, the fact shows the presence of metallic matter, which is probably copper or some remains of lead, or both. The solution, after precipitation by muriatic acid and filtration, should leave no residue when evaporated. A piece of the salt, heated on charcoal by the blowpipe, melts, deflagrates, and leaves behind a whitish metallic coating. After all, the best sign of the purity of nitrate of silver is the characteristic appearance of the crystals. For other tests, see *Argenti Nitras Fusa.*

Medical Properties. Nitrate of silver, as an internal remedy, is deemed tonic and antispasmodic. The principal diseases in which it has been employed are epilepsy, chorea, angina pectoris, and other spasmodic affections. In epilepsy it forms our most reliable remedy; but the kind of cases to which it is particularly applicable, and its modus operandi are not understood. It is said to produce most good in this disease when it acts upon the bowels. Wunderlich has found it specially useful in the affection named progressive locomotive ataxia. (*Ann. de Thérap.*, 1863, p. 210.) It is among our most efficient remedies in chronic gastritis, attended with pain and vomiting. Dr. J. F. Peebles, of Petersburg, Va., bore testimony to its efficacy in jaundice connected with gastric irritation, given preferably on an empty stomach. (*Am. Journ. of the Med. Sciences*, July, 1849.) Dr. Boudin, of Marseilles, employed it in typhoid fever as a remedy for the inflammation and ulceration of the ileum, which constitute the most constant lesion in that disease. M. Delioux, of Rochefort, has proposed albuminous injections of nitrate of silver in diarrhœa, formed of half a pint of water, containing the white of one egg, from two to four grains of the nitrate, and an equal weight of common salt. Nitrate of silver is soluble in an excess of an albuminous solution, and when thus prepared is more readily absorbed than when dissolved in water. The common salt promotes its solution without decomposing it. (*Journ. de Pharm.*, xx. 149.) In chronic diarrhœa, especially in that kind attendant on phthisis, Dr. Macgreggor, of Dublin, has found the nitrate of silver, conjoined with opium, a valuable remedy. It has also been used with supposed advantage in cholera infantum, in doses varying from one-sixteenth to one-fourth of a grain, at intervals of two, four, or six hours. Whatever may be the remedial value of this salt internally administered, its occasional effect of producing a slate-coloured discoloration of the skin, which is seldom removed, is a great objection to its use. This effect proves the absorption of the medicine, and is stated to show itself first on the tongue and fauces. According to Dr. Branson, an indication of the approach of discoloration is furnished by the occurrence of a dark-blue line on the edges of the gums, very similar to that produced by lead, but somewhat darker. For this discoloration of the skin a steady course of cream of tartar has been recommended.

Externally, nitrate of silver is occasionally employed in solution as a stimulant and escharotic; but the *fused nitrate*, which is not so pure as the officinal *nitrate* (pure salt in crystals), is generally selected for making solutions. In

cases requiring nicety, the officinal nitrate (crystals) should be directed to be dissolved, and distilled water should be selected as the solvent. A solution, made in the proportion of half a grain of the crystals to a fluidounce of distilled water, forms a good mouth-wash for healing ulcers produced by mercury. In the inflammation of the mouth from mercurial salivation, M. Bouchacourt found a concentrated solution of the salt, applied to the gums, base of the tongue, &c., with a camel's hair brush, very useful. A solution, containing from two to ten grains of the crystals to a fluidounce of distilled water, is an excellent application in ophthalmia with ulcers of the cornea, in fetid discharges from the ear, aphthous affections of the mouth, and spongy gums.

The dose of nitrate of silver (crystals) is the fourth of a grain, gradually increased to four or five grains, three times a day. For internal exhibition, the physician should always prescribe the crystals, which are meant by the name Argenti Nitras in the revised nomenclature of the U. S. Pharmacopœia of 1850, and never direct the fused nitrate (Argenti Nitras Fusa), which is often impure. Nitrate of silver should always be given in pill, in which form, according to Dr. Powell, the system bears a dose three times as large as when given in solution. In the treatment of epilepsy, this physician recommends the exhibition at first of grain doses, to be gradually increased to six grains, three times a day. Its effects vary very much, owing no doubt to the salt being more or less decomposed by the substances used in preparing it in pill, or with which it comes in contact in the stomach. It should not be made up into pill with crumb of bread, as this contains common salt, but with some vegetable powder and mucilage. But, as all organic substances more or less decompose it, M. Vée proposes the use of inorganic matter, such as nitre, or preferably pure silica obtained by precipitating one of the silicates by an acid, and washing it. The least possible proportion of tragacanth may be used to give adhesiveness to the mass. (*Journ. de Pharm.*, Mai, 1864, p. 408.) In view of the fact that chloride of sodium is used with food, and exists, together with phosphates, in the secretions, and that free muriatic acid and albuminous fluids are present in the stomach, it is almost certain that, sooner or later, the whole of the nitrate of silver will be converted into the chloride, phosphate, and albuminate, compounds far less active than the original salt. The experiments of Keller, who analyzed the feces of patients under the use of this salt, confirm this view. Such being the inevitable result when the nitrate is given, the question arises how far it would be expedient to anticipate the change, and give the silver as a chloride ready formed. One of the authors of this work has tried the chloride in large doses, in two cases of epilepsy, but without advantage. According to Mialhe, nitrate of silver upon entering the stomach is immediately changed into the chloride, and this is quickly converted into a soluble and readily absorbable double chloride, by combining with chloride of sodium or of potassium.

Nitrate of silver, in an overdose, produces the effects of the corrosive poisons. The proper antidote is common salt, which acts by converting the poison into the insoluble chloride of silver.

Off. Prep. Argenti Cyanidum, *U. S.;* Argenti Nitras Fusa, *U. S.;* Argenti Oxidum. B.

ARGENTI NITRAS FUSA. *U. S.* Argenti Nitras. *Br.* Lapis Infernalis. *Fused Nitrate of Silver. Lunar Caustic.*

"Take of Nitrate of Silver *a convenient quantity.* Melt it in a porcelain capsule, and continue the heat cautiously until frothing ceases; then pour the melted salt into suitable silver moulds." *U. S.*

"To obtain the Nitrate in rods, fuse the crystals in a dark room in a capsule of platinum or thin porcelain, and pour the melted salt into proper moulds." *Br.*

Instead of forming the nitrate of silver, as in the process of 1850, the present U. S. Pharmacopœia takes the salt already formed, and simply melts it with cer-

tain precautions. The British process is merely the continuation of that by which the nitrate is obtained in crystals. As the salt while melting sinks into a common crucible, the fusion is performed in one of porcelain or platinum, the size of which should be sufficient to hold five or six times the quantity of the salt operated on, in order to prevent its overflowing in consequence of the ebullition. Sometimes small portions of the liquid are spirted out, and the operator should be on his guard against this occurrence. When the mass flows like oil, it is completely fused, and ready to be poured into the moulds. These should be warmed, but not greased, as organic matter would thus be furnished, which would partially decompose the fused salt.*

Properties. Fused nitrate of silver, as prepared by the above process, is in the form of hard brittle sticks, of the size of a goose quill, at first translucent, but quickly becoming gray or more or less dark under the influence of light, owing to the reduction of the silver, effected probably by organic matter, or sulphuretted hydrogen contained in the atmosphere. That the change does not depend on the sole action of light has been proved by Mr. Scanlan, who finds that nitrate of silver, in a clean glass tube hermetically sealed, undergoes no change by exposure to light. The sticks often become dark-coloured and nearly black on the surface, and, when broken across, exhibit a crystalline fracture with a radiated surface. Fused nitrate of silver, when pure, is wholly soluble in distilled water; but even fair samples of the fused salt will not totally dissolve, a very scanty black powder being left of reduced silver, arising probably from the salt having been exposed to too high a heat in fusion.

Impurities and Tests. Fused nitrate of silver is liable to contain free silver from having been exposed to too high a heat, the nitrates of lead and copper from the impurity of the silver dissolved in the acid, and nitrate of potassa from fraudulent admixture. Free silver will be left undissolved as a black powder, after the action of distilled water. A very slight residue of this kind is hardly avoidable; but, if there be much free silver, it will be shown by the surface of a fresh fracture of one of the sticks presenting an unusually dark-gray colour. (*Christison.*) The mode of detecting lead and copper is explained under nitrate of silver. (See *Argenti Nitras.*) In order to detect nitre, a solution of the suspected salt should be treated with muriatic acid in excess, to remove silver, and with sulphuretted hydrogen, to throw down other metals if they happen to be present. The filtered liquid, if the salt be pure, will entirely evaporate by heat; if it contain nitre, this will be left, easily known by its properties as a nitrate. This impurity sometimes exists in fused nitrate of silver in large amount, varying, according to different statements, from 10 to 75 per cent. According to Dr. Christison, it may be suspected if the sticks present a colourless fracture. In the Br. Pharmacopœia the following method is given for testing fused nitrate of silver for impurity, without determining its nature. "Ten grains dissolved in two fluidrachms of distilled water give with hydrochloric acid a precipitate, which, when washed and thoroughly dried, weighs 8·44 grains; and the filtrate when evaporated by a water bath leaves no residue." If the weight of the precipitate be greater or less than here stated there must be some impurity in the nitrate; and any non-precipitable matter, if solid at the temperature of the water-bath, will be left behind when the filtrate is evaporated. In the U. S. Pharmacopœia, the following test, suggested by Dr. Squibb, is given to detect nitre or other saline impurity. "A small portion, rubbed into fine powder with

* For certain purposes it is desirable to have the nitrate of silver less brittle than in its pure state. Prof. J. L. Smith, of Louisville, Ky., has found that this may be effected by adding a little chloride of silver, which renders the stick tough, without materially impairing its efficiency. Dr. Squibb proposes to accomplish the object by adding 40 grains of muriatic acid, with half a fluidounce of distilled water, to two ounces of nitrate of silver, heating the mixture by means of a sand-bath to dryness, and then melting and casting into moulds. (*Proceedings of the Am. Pharm. Assoc.*, 1858.)—*Note to the twelfth edition.*

twice its weight of sugar, forms a mixture, which, when burned upon a surface of glass or porcelain, leaves a tasteless residue." If the nitrate is pure, only the reduced metal is left, which is without taste. If it contain only as much as 1 per cent. of nitre, or other saline impurity, the residue will have the sharp alkaline taste of the base of the salt. (*Am. Journ. of Pharm*, Jan. 1859, p. 50.)

Medical Properties. Fused nitrate of silver should be restricted to external use. The medical properties of the salt, as an internal remedy, are given under the head of the *crystallized* nitrate. (See *Argenti Nitras.*) Externally applied the fused nitrate acts variously as a stimulant, vesicant, and escharotic, and may be employed either dissolved in water, or in the solid state. Dissolved to the extent of from one to five grains in a fluidounce of water, it is used for the purpose of stimulating indolent ulcers, and as an injection for fistulous sores. A drachm of the fused salt, dissolved in a fluidounce of water, forms an escharotic solution, which may often be resorted to with advantage. When used in solution it is most conveniently applied by means of a camel's hair brush. But fused nitrate of silver is most frequently employed in the solid state; and, as it is not deliquescent nor apt to spread, it forms the most manageable caustic that can be used. When thus employed, it is useful to coat the caustic, as recommended by M. Dumeril, by dipping it into melted engravers' sealing-wax, which strengthens the stick, protects it from change, prevents it from staining the fingers, and affords facilities for limiting the action of the caustic to particular spots. If it is desired, for example, to touch a part of the throat with the caustic, it is prepared by scraping off the sealing-wax with a penknife, to a suitable extent from one end. Another way to strengthen the stick is to cast it around a platinum wire, as recommended by M. Chassaignac; or around a wick of cotton, according to the plan of M. Blatin. By the latter plan, when the stick is broken, the fragments remain attached. If the fused nitrate be rubbed gently over the moistened skin until this becomes gray, it generally vesicates, causing usually less pain than is produced by cantharides. The fused nitrate is also employed to destroy strictures of the urethra, warts and excrescences, fungous flesh, incipient chancres, and the surface of other ulcers. Mr. Higginbottom considers its free application to ulcers, so as to cover them with an eschar, as an excellent means of expediting their cicatrization. He alleges that, if an adherent eschar be formed, the parts underneath heal before it falls off. It has also been used with good effect in the solid state, by Dr. Jewell in leucorrhœa, and by Ricord, Hannay, and others in the gonorrhœa of women. In these cases the pain produced is much less than would be expected. Lunar caustic is frequently used in aqueous solution as a topical remedy in various low forms of inflammation, but particularly in erysipelas, applied both to the inflamed and to the surrounding healthy parts. In some cases it is sufficient to blacken the cuticle; in others it is best to produce vesication. In the treatment of these inflammations, Mr. Ward, of London, finds an ethereal solution, formed by dissolving eight grains of the salt in a fluidounce of common nitric ether, much more convenient and manageable than an aqueous solution. The ethereal solution is readily applied, and quickly dries. Dr. J. Wiltbank, of this city, uses an aqueous solution of nitrate of silver (from twenty to forty grains to the fluidounce) in the treatment of superficial burns and scalds, applied with a camel's hair brush over the whole surface, first wiped dry, after opening the vesications. If the burn be deep, the entire surface of the ulcer should be touched with the stick. (*Med. Exam.*, March, 1856, p. 144.) In cases of prolapsus ani, Mr. Lloyd, of London, smears the whole surface of the protruded bowel with the solid caustic, and then returns it. Three or four applications, at intervals of a week or fortnight, are generally sufficient to effect a cure. Mr. Lloyd never knew this practice to be attended with bad consequences. Prof. Parker, of New York, uses nitrate of silver for the radical cure of hydrocele. After drawing off the liquid, he introduces, through the can-

nula, a common probe, the end of which is coated, for half an inch or more, with the caustic. The probe is then carried lightly over the serous surface of the tunica vaginalis, and withdrawn. In smallpox it has been proposed by Bretonneau and Serres to cauterize each pustule, after its top has been removed, on the first or second day of the eruption, in order to arrest its development, and prevent pitting. The fused nitrate also forms an efficacious application to certain ulcerations of the throat, to different forms of porrigo of the scalp and other skin diseases, to punctured and poisoned wounds, and to chilblains, slowly rubbed over the moistened part. If, unexpectedly, the pain produced by its external use should be excessive, it may be immediately allayed by washing the parts with a solution of common salt, which acts by decomposing the caustic. In the form of ointment, made by mixing one part of the caustic, in powder, with thirty of lard, it has been used in ozæna; a piece of lint, smeared with the ointment, being introduced into the nasal fossa.

Nitrate of silver, in impalpable powder, mixed with an equal weight of lycopodium, and used by inhalation, has been found beneficial in ulcerated sorethroat, laryngitis, bronchitis, and incipient phthisis, by Dr. W. M. Cornell, of Boston (*Boston Med. and Surg. Journ.*, Sept. 25, 1850.) The salt, used in this way, has since been successfully employed in the treatment of chronic laryngitis by M. Trousseau, of Paris, and others. The mixture employed consisted of three grains of the nitrate and a drachm of sugar of milk, intimately mixed in fine powder, of which as much as would fill the barrel of a steel pen was inhaled daily. The steel pen, charged with the powder, and attached to the barrel of a quill, is placed on the root of the tongue, and the patient compresses his lips around the quill. Then holding his nose, he makes a deep inspiration, which draws the powder into the larynx. (See *Am. Journ. of Med. Sci.*, Oct. 1855, p. 515.) This plan of applying nitrate of silver to the larynx is much more sure and safe than that of introducing the solution by injection, or by means of a sponge. B.

ARGENTI OXIDUM. *U. S.*, *Br. Oxide of Silver.*

"Take of Nitrate of Silver *four troyounces;* Distilled Water *half a pint;* Solution of Potassa *a pint and a half,* or *a sufficient quantity.* Dissolve the Nitrate of Silver in the Water, and to the solution add Solution of Potassa so long as it produces a precipitate. Wash this repeatedly with water until the washings are nearly tasteless. Lastly, dry the precipitate and keep it in a well stopped bottle, protected from the light." *U. S.*

"Take of Nitrate of Silver, in crystals, *half an ounce* [avoirdupois]; Solution of Lime *three pints and a half* [Imperial measure]; Distilled Water *ten fluidounces.* Dissolve the Nitrate of Silver in four [fluid]ounces of the Distilled Water, and, having poured the solution into a bottle containing the Solution of Lime, shake the mixture well, and set it aside to allow the deposit to settle. Draw off the supernatant liquid, collect the deposit on a filter, wash it with the remainder of the Distilled Water, and dry it at a heat not exceeding 212°. Keep it in a stoppered bottle." *Br.*

Oxide of silver was introduced into the U. S. Pharmacopœia of 1850, and was adopted in the Br. Pharmacopœia from the Dublin. In the processes for making it, nitrate of oxide of silver is decomposed by potassa or lime, the oxide being precipitated, and nitrate of potassa or nitrate of lime, as the case may be, remaining in solution. When thus obtained the oxide is an olive-brown powder. If the potassa used be not wholly free from carbonic acid, the precipitated oxide will be contaminated with some carbonate of silver. According to Mr. Borland, of London, the carbonate is sometimes sold for the oxide. A third process for obtaining this oxide is that of Gregory, which consists in boiling the moist, recently prepared chloride of silver with a very strong solution of caustic potassa (sp. gr. 1·25 to 1·30). In this case, by double decomposition, oxide of silver and chloride of potassium are formed. When thus prepared it is a very dense pure black

powder. Oxide of silver is very slightly soluble in water. Exposed to heat it gives out oxygen, and is wholly converted into metallic silver; 29 grains of it yielding 27 of the metal. (*Br.*) It should not effervesce with acids. When its solution in nitric acid is precipitated by chloride of sodium in excess, the supernatant liquid is not discoloured by bihydrosulphate of ammonia. The non-action of this test shows the absence of most foreign metals, especially copper and lead. It parts with its oxygen with great facility, being decomposed by many organic substances, and even causing sulphur to take fire when the two are rubbed together, quite dry, in a mortar. (*Chem. News*, May 7, 1864, p. 217.) Oxide of silver consists of one eq. of silver 108, and one of oxygen 8=116.

Medical Properties. This oxide has been proposed as a substitute for nitrate of silver, as having the general therapeutic virtues of the latter, without its escharotic effect, and objectionable property of discolouring the skin. It was first tried as a medicine by Van Mons and Sementini. In 1840 it was employed by Dr. Butler Lane, who considered it to act as a sedative. In 1845 the late Sir James Eyre strongly recommended it in his work on exhausting diseases. Dr. Lane used it with more or less success in nausea, cardialgia, pyrosis, various painful affections of the stomach without organic lesion, dysentery, diarrhœa, night-sweats without other obvious affection, dysmenorrhœa, menorrhagia, leucorrhœa, chronic enlargements of the uterus attended with flooding, &c. The oxide appeared to exert a peculiar control over uterine fluxes. Some of the cases treated required the use of tonics, after the curative influence of the oxide had been exerted. The late Dr. Golding Bird also obtained favourable effects from the use of oxide of silver, and confirmed to a certain extent the results of Dr. Lane, especially as to its valuable powers in menorrhagia. Thus far no case of cutaneous discoloration is known to have occurred; though Dr. Lane gave the oxide repeatedly for two months, and Dr. Bird in more than a hundred cases, in one for four months. Dr. Lane observed one case in which repeated salivation occurred, and Dr. Bird several in which the gums were affected. But, in order to draw any inference from these results, the prescriber should be certain that the medicine is not contaminated with black oxide of mercury. In stomach disease, characterized by a glairy instead of a watery discharge, Dr. Bird derived not the slightest benefit from the oxide, though he used it in thirty cases. In epilepsy it is supposed by some that the oxide will accomplish all that can be expected from the nitrate, with less risk to the stomach, and without incurring the danger of discolouring the skin. In tænia it has been used successfully in two cases by Mr. Whittel. The dose of oxide of silver is a grain, twice or thrice a day, given in pill. In no case did Dr. Lane carry the dose beyond six grains in the twenty-four hours. The pills should not be made with honey, conserve of roses, or other excipient containing glucose; and, indeed, most organic substances, especially in a moist state, deoxidize the oxide, reviving the silver. Mr. Ambrose Smith recommends, as among the best excipients, gum arabic, or this with a little syrup. (*Proceed. of Am. Pharm. Assoc.*, 1859, p. 308.) Oxide of silver has been used in the form of ointment, composed of from five to ten grains to the drachm of lard, as an application to venereal sores, and to the urethral membrane in gonorrhœa, smeared on a bougie. B

ARSENICUM.

Preparation of Arsenic.

The officinal liquid preparations of arsenic are, in compliance with the Pharmacopœias, considered under the head of *Liquores* or *Solutions*. (See *Liquor Arsenici et Hydrargyri Iodidi*, *Liquor Potassæ Arsenitis*, and *Liquor Sodæ Arsenitis*, in *Part II.*) It is only the Iodide of Arsenic that is treated of in this place.

ARSENICI IODIDUM. *U. S. Iodide of Arsenic.*

"Take of Arsenic *sixty grains;* Iodine *three hundred grains.* Rub the Arsenic in a mortar until reduced to a fine powder; then add the Iodine, and rub them together until they are thoroughly mixed. Put the mixture into a small flask or a test-tube, loosely stopped, and heat it very gently until liquefaction occurs. Then incline the vessel in different directions, in order that any portion of the Iodine, which may have condensed on its surface, may be returned into the melted mass. Lastly, pour the melted Iodide on a porcelain slab, and, when it is cold, break it into pieces, and keep it in a well-stopped bottle." *U. S.*

This iodide was introduced into the U. S. Pharmacopœia for the purpose of being used in preparing the solution of iodide of arsenic and mercury. It is made by the direct combination of its constituents, with the aid of a gentle heat.

Properties, &c. Iodide of arsenic is an orange-red, crystalline solid, entirely soluble in water, and wholly volatilized by heat. In composition it is considered to be a *teriodide*, consisting of one eq. of arsenic 75, and three of iodine 378·9 = 453·9. It has been used by Biett as an external application in corroding tubercular skin diseases. By the late Dr. A. T. Thomson it was given internally with advantage in lepra, impetigo, and diseases resembling cancer. Dr. F. C. Crane cured a case of what he considered cancer of the breast by its use for nearly eight months. The ointment used by Biett was composed of three grains of the iodide to an ounce of lard. The dose for internal exhibition is an eighth of a grain three times a day, given in pill or solution.

Off. Prep. Liquor Arsenici et Hydrargyri Iodidi. B.

ATROPIA.

Preparations of Atropia.

ATROPIA. *U. S., Br. Atropia.*

"Take of Belladonna Root, in fine powder, *forty-eight troyounces;* Purified Chloroform *four troyounces and a half;* Diluted Sulphuric Acid, Solution of Potassa, Alcohol, Water, each, *a sufficient quantity.* Mix the powder with a pint of Alcohol, and, having introduced the mixture into a cylindrical percolator, pour Alcohol gradually upon it until sixteen pints have passed. From the liquid, thus obtained, distil off twelve pints of alcohol. To the residue add sufficient Diluted Sulphuric Acid to give it an acid reaction, and, having evaporated the liquid to half a pint, add an equal bulk of Water, and filter through paper. To the filtered liquid add, first a troyounce and a half of the Chloroform, and then Solution of Potassa in slight excess, and shake the whole together, at intervals, for half an hour. When the heavier liquid has subsided, separate it, and, having added a troyounce and a half of the Chloroform to the lighter liquid, again shake them together, and separate the heavier from the lighter liquid as before. Add to this lighter liquid the remainder of the Chloroform, and, after agitation, separate the heavier liquid for the third time. Mix the heavier liquids in a capsule, and set the mixture aside until, by spontaneous evaporation, the Atropia is left dry." *U. S.*

"Take of Belladonna Root, recently dried and in coarse powder, *two pounds* [avoirdupois]; Rectified Spirit *ten pints* [Imperial measure]; Slaked Lime *one ounce* [avoird.]; Water *half a fluidounce;* Distilled Water *ten fluidounces;* Chloroform *three fluidounces;* Dilute Sulphuric Acid, Carbonate of Potash, and Purified Animal Charcoal, each, *a sufficiency.* Macerate the Root in two quarts [Imp. meas.] of the Spirit, for twenty-four hours, with frequent stirring. Transfer to a displacement apparatus, and exhaust with the remainder of the Spirit by slow percolation. Add the Lime to the tincture placed in a bottle, and shake occasionally several times. Filter, add the Dilute Sulphuric

Acid in very feeble excess, and filter again. Distil off three-fourths of the Spirit, add to the residue the Distilled Water, evaporate at a gentle heat, but as rapidly as possible, until the liquid is reduced to one-third of its volume and no longer smells of alcohol; then let it cool. Add very cautiously, with constant stirring, a solution of the Carbonate of Potash so as nearly to neutralize the acid, care, however, being taken that an excess is not used. Set to rest for six hours, then filter, and add Carbonate of Potash in such quantity that the liquid shall acquire a decided alkaline reaction. Place it in a bottle with the Chloroform; mix well by frequently repeated brisk agitation, and pour the mixed liquids into a funnel furnished with a glass stop-cock. When the Chloroform has subsided, draw it off by the stop-cock, and distil it on a water-bath from a retort connected with a condenser. Dissolve the residue in warm Rectified Spirit; digest the solution with a little Animal Charcoal; filter, evaporate, and cool until colourless crystals are obtained." *Br.*

The U. S. process is a modification of the one proposed by Prof. Procter in a communication to the American Pharmaceutical Association, published in their Proceedings for the year 1860. The root is first exhausted by alcohol, by means of percolation, a large proportion of the alcohol is distilled off, and sulphuric acid is added in slight excess, so as to convert the atropia into the sulphate, and thus enable it to be held in solution in the next step of the process. The liquid is now further concentrated, so as to separate nearly all the alcohol, and then mixed with water to separate resinous and fatty matters. The sulphate of atropia is left in solution. This, after filtration, is treated with chloroform and solution of potassa in slight excess, the latter to separate the atropia from the sulphate, and the former to dissolve it when thus separated; and the repeated agitation with the chloroform is in order that the whole of the atropia may be dissolved. Chloroform is admirably adapted to this purpose, at once by its insolubility in water, and by its extraordinary solvent power over atropia, of which it is capable of taking up 33 per cent. The chloroformic solution sinks to the bottom in consequence of its density, and, having been separated, yields the atropia by spontaneous evaporation. The alkaloid as thus obtained is not pure, still containing resinous and colouring matters; but it was deemed sufficiently so for medical use. This we think unfortunate; for it is impossible, unless the alkaloid be obtained pure or very nearly so, to determine, in any particular instance, unless by a complicated operation, the precise amount of impurity, and consequently the precise strength of the preparation. Had it been deemed advisable to follow the process of Mr. Procter, in all its steps, this result might have been avoided. Though atropia is very soluble in chloroform, the sulphate of that alkaloid is insoluble. Consequently, if the impure solution of the sulphate left after the precipitation of the resinous matter by water, be thoroughly agitated, as suggested by Mr. Procter, with a portion of chloroform, it is deprived of most of its remaining resinous, fatty, and colouring matters, still retaining the alkaloid in the form of sulphate, which, after the removal of the chloroform, it will yield in a comparatively pure state to the subsequent treatment by solution of potassa and chloroform. Though caustic potassa is believed to decompose atropia by prolonged contact, yet, in this instance, its opportunity for any injurious action would be too fugitive to justify apprehension on this score; for it speedily becomes neutralized by the sulphuric acid, while the liberated alkaloid is as quickly seized by the chloroform, and carried out of its sphere of action. But, even with this improvement of the process, the alkaloid, as yielded by the spontaneous evaporation, is not quite free from impurity, and, to be obtained entirely pure and colourless, should be dissolved in alcohol, treated with a little animal charcoal, and then allowed to crystallize by the spontaneous evaporation of the alcoholic solution after filtration. Prof. Procter obtained only about one-third of 1 per cent. of pure atropia from the amount of root used. The use of chloroform as a

solvent of atropia, in preparing that alkaloid, was, we believe, first suggested by M. Rabourdin, of Orleans, in France. The application of it to the purification of the impure sulphate originated with Prof. Procter. As chloroform is too valuable to be lost when it can conveniently be saved, it would be advisable, when it is used in this process, instead of allowing it to escape by spontaneous evaporation, to recover it by distillation with a warm-bath, taking care, by using a temperature not exceeding 160° F., to shun any danger of decomposing the atropia.

The British process, as will be seen by comparing it with the notes below, is a combination of the processes of Mein and Rabourdin, the former being followed until after the addition of carbonate of potassa, and the alkaloid thus liberated being taken up by chloroform as in the latter. The use of lime in the earlier stage of the proceedings is to cause a precipitation of various substances which would otherwise embarrass the subsequent operations.*

Properties. Atropia is in silky, prismatic, acicular crystals, which, when quite pure, are colourless, but, as obtained according to our officinal formula, are yellow-

* The following is the process employed by Mein for procuring atropia. The roots of plants two or three years old were selected. Of these, in extremely fine powder, 24 parts were digested, for several days, with 60 parts of alcohol of 86 or 90 per cent. The liquid having been separated by strong expression, the residue was treated anew with an equal quantity of alcohol; and the tinctures, poured together and filtered, were mixed with one part of hydrate of lime, and frequently shaken for 24 hours. The copious precipitate which now formed was separated by filtering; and diluted sulphuric acid was added drop by drop to the filtered liquor, till slightly in excess. The sulphate of lime having been separated by a new filtration, the alcoholic liquid was distilled to one-half, then mixed with 6 or 8 parts of pure water, and evaporated with a gentle heat till the whole of the alcohol was driven off. The residual liquid was filtered, cautiously evaporated to one-third, and allowed to cool. A concentrated aqueous solution of carbonate of potassa was then gradually added, so long as the liquid continued to be rendered turbid; and the mixture was afterwards suffered to rest some hours. A yellowish resinous substance, which opposes the crystallization of the atropia, was thus precipitated. From this the liquid was carefully decanted, and a small additional quantity of the solution of the carbonate was dropped into it, till it no longer became turbid. A gelatinous mass now gradually formed, which, at the end of twelve or twenty-four hours, was agitated in order to separate the mother-waters, then thrown upon a filter, and dried by folds of unsized paper. The substance thus obtained, which was atropia in an impure state, was dissolved in five times its weight of alcohol; and the solution, having been filtered, was mixed with six or eight times its bulk of water. The liquor soon became milky, or was made so by evaporating the excess of alcohol, and, in the course of 12 or 24 hours, deposited the atropia in the form of light-yellow crystals, which were rendered entirely pure and colourless by washing with a few drops of water, drying on blotting paper, and again treating with alcohol. From 12 oz. of the root, Mein obtained 20 grs. of the alkaloid. (*Journ. de Pharm.*, xx. 87.)

M. Rabourdin, of Orleans, in France, prepares atropia by means of chloroform in the following manner. To each litre (about 2 pints) of the expressed juice of the fresh leaves, deprived of its albumen by heat and filtration, or to a filtered solution of 60 grammes (about 15 drachms) of extract in 200 grammes of distilled water, 4 grammes of potassa, and 30 grammes of chloroform are added, the whole is shaken for a minute, and then set aside. In half an hour, the chloroform, holding the atropia in solution, is seen at the bottom of the vessel, resembling a greenish oil. The supernatant liquor is decanted, and small portions of water successively added and removed, until no longer rendered turbid. The chloroformic solution is then distilled, by means of a salt-water bath, until all the chloroform has passed. The residue is treated with a little water acidulated with sulphuric acid, which dissolves the atropia, leaving a green resinous matter. The solution is then filtered, the atropia precipitated by carbonate of potassa in slight excess, and the precipitate dissolved in rectified alcohol, which, upon evaporation, yields it in beautiful groups of needles. (*Gaz. Méd. de Paris*, Oct. 19, 1850.)

Mr. W. T. Luxton obtains atropia by adding a little sulphuric acid to a strong decoction of the leaves so as to precipitate the albumen, filtering, and either passing gaseous ammonia through the clear liquor, or suspending in it a lump of carbonate of ammonia. Atropia slowly crystallizes, and in a day or two may be separated on a filter, and deprived of colour by washing with spirit of ammonia. Mr. Luxton obtained between 5 and 6 grains from 1000 of the leaves. (See *Am. Journ. of Pharm.*, xxvii. 156.)

An account of the effects of numerous reagents upon the muriate of atropia, by Dr. A. Von Planta, may be found in the *American Journal of Pharmacy* (xxiii. 38).

ish-white. It is inodorous, but has a bitter and acrid taste. It melts at 194° F., and at 284° is volatilized, a portion being unchanged, but the greater part destroyed. It is inflammable, giving off an odour like that of benzoic acid, and, when burned in the open air, leaving no residue. By distilling it with bichromate of potassa and sulphuric acid, Dr. E. Pfeiffer succeeded in obtaining crystals of benzoic acid. (*Am. J. of Pharm.*, May, 1864, p. 226.) Dr. Kraut, by heating it with baryta-water, succeeded in obtaining an uncrystallizable salt, consisting of a peculiar acid and peculiar base, the former of which he calls *atropic acid* and the latter *tropia*. (*Ibid.*, p. 232.) It is said, moreover, that when a little of it, dissolved in a few drops of sulphuric acid, is heated, an odour is given out resembling that of orange flowers. (*Ibid.*, March, 1864, p. 112.) It is soluble in 300 parts of water at 60°, in 25 parts of ether, less so in alcohol, and, according to Schlimpert, in a little more than 3 parts of chloroform; and in all these liquids it is more soluble hot than cold. It has a strong alkaline reaction, forms crystallizable salts with acids, and, in solution, gives a lemon-yellow precipitate with terchloride of gold. Heated with potassa or soda it gives out ammonia, and is rendered inert by prolonged contact with the former alkalies. In very dilute solution, it produces, when applied to the eye, a speedy and durable dilatation of the pupil. Its composition is represented by the formula $C_{34}H_{23}NO_6$.

Medical Properties and Uses. The effects of atropia on the system are precisely those of belladonna, whether locally or generally, whether in moderate doses as a remedy, or in excessive quantities as a poison. It is in general, however, somewhat more speedy in its operation, probably in consequence of its easier absorption. Thus, the poisonous action of belladonna is seldom experienced in less than half an hour, while that of atropia shows itself violently in fifteen or twenty minutes. The most prominent effects from the smallest remedial doses are dryness and stricture of the throat, and slight uneasiness of the head, with confusion or giddiness; from somewhat larger doses, dilatation of the pupil, some dimness of vision, frontal headache, slight delirium, flushed face, and sometimes a scarlet rash; from poisonous doses, the above symptoms in a more aggravated form, great dimness or total temporary loss of vision, excessive dilatation of the pupil, intense headache or violent delirium followed by stupor, paralytic sensations, intense redness of the face, neck, &c., at first acceleration but afterwards depression of the pulse, and finally great prostration, profound coma, coldness of the extremities, and death, if relief is not obtained. Sometimes nausea and vomiting are produced, and occasionally diarrhœa. There is often an increased disposition to micturate; and atropia has been detected in the urine of those who have taken it freely. In a case recorded by Dr. James Andrew two-thirds of a grain occasioned the most alarming symptoms, which continued for several days (*Ed. Month. Journ. of Med. Sci.*, xiv. 34); and a lady, under the care of M. Roux, of Brignolles, took somewhat more than a grain, with the same threatening symptoms (*Ann. de Thérap.*, 1861, p. 14); though, in both cases, recovery took place under treatment. In a child of three years old less than half a grain was followed by the same alarming symptoms, and the same favourable result. (*Med. Times and Gaz.*, Dec. 1850, p. 601.) A solution of atropia dropped into the eye produces dilatation of the pupil after ten or fifteen minutes, without causing congestion or inflammation; and the dilatation will usually continue for two or three days. Sometimes it is said that the dilatation is followed by contraction of the pupil, especially when the dose is large. The alkaloid also produces its characteristic constitutional effects when applied to the skin denuded of the epidermis, or to a mucous membrane, as of the rectum, vagina, &c., and especially when injected into the subcutaneous areolar tissue. The remedies for its poisonous operation are the same as those for belladonna; the most prominent being evacuation of the stomach, cold applications to the head, the preparations of opium internally, and stimulants when the strength is

failing. The officinal compound solution of iodine has been given in poisoning by atropia, and with apparent advantage, in one or two cases, though other remedies were employed at the same time. It acts by forming an insoluble compound with the alkaloid. (See *Belladonna.*)

Atropia may be used internally for all the purposes for which belladonna is given; but it is chiefly as a local remedy, for application to the eye, or to the surface of the body, or for subcutaneous injection that it is preferred; and for these purposes it has the advantage over the ordinary preparations of belladonna, of greater precision of dose, quicker action, and greater neatness and cleanliness. The dose to begin with, for internal use, is about one-thirtieth of a grain, which may be gradually increased till some effect is experienced; but it is almost too powerful for prudent employment in this way, especially as all the effects of belladonna may be readily obtained from the extract. Dr. Sieveking found, in a trial upon himself, that one-hundredth of a grain produced brief vertigo followed by dryness of the throat, without affection of the viscera, but with nervous depression next day. (*B. and F. Med.-Chir. Rev.*, July, 1858, Am. ed., p. 179.) It may be given dissolved in diluted alcohol, in the proportion of two grains to half a fluidounce, of which four minims, or twice the number of drops may be given for a commencing dose. If given in pill, the greatest care should be taken to distribute the atropia equally in the pill-mass before dividing it. For application to the eye, one grain may be dissolved in four fluidrachms of distilled water by means of a few drops of acetic acid, of which no more should be used than is necessary to effect the solution. Of this, a single drop, applied to the inner surface of the lower lid, will produce dilatation of the pupil in 15 or 20 minutes. The same solution may be used for subcutaneous injection in the quantity of 8 or 10 drops to commence with, and gradually increased. For application to the sound skin, the form of ointment is most convenient. This may be made by rubbing a grain of the alkaloid first with four minims of alcohol, and then with a drachm of lard. Glycerin and olein also have been recommended as vehicles of atropia for external use; and may be incorporated with it in the same proportion.

When solution of atropia is used locally for dilating the pupil, it may be either dropped into the eye within the lower lid, or may be introduced on small slips of paper previously saturated with the solution and dried, or, what is still more convenient, by means of minute circular discs of gelatin, made by mixing the solution with gelatin and evaporating so as to procure a thin film, which is to be cut into circular pieces. These have the advantage over paper that they do not require to be subsequently removed from the eye.

Off. Prep. Atropiæ Sulphas, *U. S.*; Liquor Atropiæ, *Br.*; Unguentum Atropiæ, *Br.* W.

ATROPIÆ SULPHAS. *U. S. Sulphate of Atropia.*

"Take of Atropia *sixty grains*; Stronger Ether *four fluidounces and a half*; Sulphuric Acid *six grains*; Stronger Alcohol *a fluidrachm*. Dissolve the Atropia in the Ether; then mix the Acid and Alcohol, and add the mixture, drop by drop, to the ethereal solution until the Atropia is saturated. Allow the liquid to stand until the precipitate formed is deposited. Then decant the ether, and expose the residue to spontaneous evaporation until the salt is dry." *U. S.*

This is essentially the process of M. Ch. Maitre, which is contained in a note in the 11th edition of the Dispensatory. Atropia being soluble in ether while its sulphate is insoluble in that fluid, a convenient method is afforded for preparing the sulphate with little evaporation. By adding the mixed acid and alcohol to the ethereal solution, the sulphate is formed, and being insoluble in the ether is deposited; while the little left dissolved in the alcohol is obtained by spontaneous evaporation. The quantity of acid added is intended to saturate the alkaloid; but if the saturation should not be exact, it would be easy to render it so by

the addition of a little more of the alkaloid or a little more of the acid, as the case may be.

From the great facility with which atropia undergoes change, much caution is necessary in preparing its salts; and the process was arranged in reference to this caution. Upon the addition of the mixed acid and alcohol to the ethereal solution, the liquid becomes milky, and deposits on the sides of the vessel a copious precipitate, of a viscid appearance, which soon dries upon the decantation of the ether, and the placing of the vessel in a drying room. To succeed with this process, it is necessary that the liquids employed should be carefully freed from water, the sulphuric acid being monohydrated, and that the temperature should be kept as low as possible. There should be no excess of acid; and, if such an excess should be found upon applying the test of litmus paper, the solution should be neutralized by a portion of reserved solution of atropia. (*Am. Journ. of Pharm.*, xxviii. 361, from *Repert. de Pharm.*)

Sulphate of atropia, as thus obtained, is a white slightly crystalline powder, having the taste of atropia, very soluble in water and alcohol, but insoluble in ether and chloroform. It should be dissipated by heat, and neutral to test-paper. It is known to be a sulphate by giving a white precipitate with chloride of barium, and a salt of atropia by its effect in dilating the pupil, when a drop of a weak solution is introduced into the eye.

If it be required to procure the sulphate in the form of crystals, which may sometimes be desirable to avoid adulteration, the process of M. Lanceau may be employed. A solution of crystallized atropia in absolute alcohol, in the proportion of 2·89 parts of the former to 4 parts of the latter by weight, having been made with the assistance of a gentle heat, 0·4 parts of sulphuric acid of the sp. gr. 1·85, diluted with 3 parts of absolute alcohol, are to be gradually added, and stirred with a glass rod, until saturation, as shown by test paper, is effected. The solution is then allowed to evaporate spontaneously, and the thinner the stratum the sooner will the process be completed. The crystals are in colourless needles more or less interlaced. (See *Am. Journ. of Pharm.*, July, 1863, p. 315.)

The effects of the salt on the system are precisely the same as those of atropia, and it may be used in the same dose. Its only advantage over the alkaloid is its solubility in water. A solution of this salt in the proportion of one part to one hundred of the solvent has been found instantaneously efficacious in the relief of toothache, applied in the quantity of a drop or two to the denuded dental pulp; and it is said, in the same quantity, to produce complete insensibility of the dental nerves, in cases in which an artificial tooth is inserted in a living root. (*Ann. de Thérap.*, 1861, p. 19.)* W.

* *Valerianate of Atropia.* This salt has been supposed to have peculiar virtues; though, in consideration of the very minute proportion of the valerianic acid in each dose, it is extremely doubtful whether it is capable, in any appreciable degree, of modifying the influence of the alkaloid. It may be prepared by dissolving 38 parts of pure and dry atropia in 140 parts of alcohol of 85°, and mixing the solution with another made by dissolving 12 parts of pure valerianic acid in 10 parts of alcohol of the same strength; and allowing the mixed liquids to evaporate spontaneously at a heat of from 86° to 100° F. (*Journ. de Pharm.*, Mars, 1864, p. 236.) According to M. Michéa, the valerianate of atropia produces the effects of this alkaloid in smaller doses than the sulphate or even atropia itself. He has often known half a milligramme (about $\frac{1}{130}$ gr.) to produce dryness of the throat and dilatation of the pupils the day after its exhibition, while it is generally not till the expiration of several days that he had been able to obtain the same effect from double the dose of the sulphate given daily. He also found less of the valerianate required than of the sulphate to modify the paroxyms of epilepsy. (*Ann. de Thérap.*, 1864, p. 31.) In the *Journal de Pharmacie* for Nov. 1858 (p. 347) there is a particular account of the chemical properties and mode of procuring valerianate of atropia in the crystalline form, to which the reader is referred. It is probable that, as in the case of valerianate of ammonia, less difficulty will be found, if our officinal monohydrated valerianic acid is employed.—*Note to the twelfth edition.*

BARIUM.

Preparation of Barium.

BARII CHLORIDUM. *U. S. Chloride of Barium. Muriate of Baryta.*

"Take of Carbonate of Baryta, in small pieces, Muriatic Acid, each, *four troyounces;* Water *a pint.* Mix the Acid with the Water, and gradually add the Carbonate of Baryta. Towards the close of the effervescence apply a gentle heat, and, when chemical action has ceased, filter the liquid, and evaporate so that crystals may form when it cools." *U. S.*

When carbonate of baryta is employed for obtaining chloride of barium, as in the officinal process, the reactions are very simple. The muriatic acid displaces the carbonic acid with effervescence; and, by reacting with the baryta, forms chloride of barium and water. The solution of chloride of barium, thus obtained, yields crystals of the chloride by concentration and cooling. Another plan is that which procures it from the sulphate, as directed in the late Edinburgh Pharmacopœia. In this the sulphate, previously ignited and powdered, is mixed with charcoal and exposed to a low white heat, by which its constituents are deoxidized, and sulphuret of barium produced; the oxygen escaping in combination with the carbon as carbonic oxide and acid. The sulphuret of barium, after having been dissolved in water, is decomposed by the addition of muriatic acid; sulphuretted hydrogen being evolved, and chloride of barium formed in solution, from which, in the usual manner, the solid salt is obtained.

Of these processes, that in which the native carbonate is used is the simplest and most convenient; but the carbonate is comparatively a rare mineral, and, as the sulphate in fine powder is a cheap article of commerce, being extensively employed for mixing with white lead, it is almost always used for obtaining chloride of barium and the other barium compounds.

Properties. Chloride of barium is a permanent white salt, possessing a bitter and disagreeable taste. It crystallizes in rhombic tables with beveled edges. It dissolves in about two and a half times its weight of cold water, and in a little more than its own weight at 222°, the boiling point of a saturated solution. It is scarcely soluble in absolute alcohol, but dissolves in rectified spirit. Alcohol, impregnated with it, burns with a yellow flame. When exposed to heat, it decrepitates and loses its water of crystallization, and at a red heat fuses. It is decomposed by the sulphates, oxalates, and tartrates, and the alkaline phosphates, borates, and carbonates; also by nitrate of silver, acetate and phosphate of mercury, and acetate of lead. When pure it does not deliquesce. Its solution is not affected by ammonia, which proves the absence of alumina and sesquioxide of iron, or by sulphuretted hydrogen, which shows that neither copper nor lead is present. After the whole of the barium has been precipitated by an excess of sulphuric acid, the supernatant liquid is shown to be free from lime by the non-action of carbonate of soda. Lime may be separated by the process of Dr. Wolcott Gibbs, which consists in adding to the solution of the chloride a small portion of the solution of hydrate of baryta, and then passing through it a current of carbonic acid, when the whole of the lime will be thrown down as a carbonate. (Wurtz, *N. Y. Journ. of Pharm.*, i. 164.) If strontia be present, an alcoholic solution of the salt will burn with a red flame. Like all the soluble salts of barium it is poisonous. It consists of one eq. of chlorine 35·5, one of barium 68·7, and two of water 18 = 122·2. It is used in medicine only in solution. The officinal solution, Liquor Barii Chloridi, is treated of among the LIQUORES, or *Solutions.*

Off. Prep. **Liquor Barii Chloridi** *U. S.* B

BEBERIA.

Preparation of Bebeeria.

BEBERIÆ SULPHAS. *Br. Sulphate of Bebeeria.*

"Take of Bebeeru Bark [Nectandra, *U. S.*], in coarse powder, *one pound* [avoirdupois]; Sulphuric Acid *half a fluidounce;* Slaked Lime *three-quarters of an ounce,* or *a sufficiency;* Rectified Spirit *sixteen fluidounces,* or *a sufficiency;* Solution of Ammonia, Dilute Sulphuric Acid, Distilled Water, each, *a sufficiency;* Water *one gallon* [Imperial measure]. Add the Sulphuric Acid to the Water; pour upon the Bark enough of this mixture to moisten it thoroughly; let it macerate for twenty-four hours; place it in a percolator, and pass through it the remainder of the acidulated water. Concentrate the acid liquor to the bulk of one pint, cool, and add gradually the Lime in the form of milk of lime, agitating well, and taking care that the fluid still retains a distinct acid reaction. Let it rest for two hours; filter through calico; wash the precipitate with a little cold Distilled Water, and add to the filtrate Solution of Ammonia until the fluid has a faint ammoniacal odour. Collect the precipitate on a cloth, wash it twice with ten ounces of cold water, squeeze it gently with the hand, and dry it on the vapour bath. Pulverize the dry precipitate, put it into a flask with six ounces of the Rectified Spirit, boil, let it rest for a few minutes, and pour off the spirit. Treat the undissolved portion in a similar manner with fresh Spirit until it is exhausted. Unite the spirituous solutions, add to them four ounces of Distilled Water, and distil so as to recover the greater part of the spirit. To the residue of the distillation add by degrees, and with constant stirring, Dilute Sulphuric Acid till the fluid has a slight acid reaction. Evaporate the whole to complete dryness on the water-bath, pulverize the dry product, pour on it gradually one pint [Imp. meas.] of cold Distilled Water, stirring diligently, filter through paper, evaporate the filtrate to the consistence of syrup, spread it in thin layers on flat porcelain or glass plates, and dry it at a heat not exceeding 140°. Preserve it in stoppered bottles." *Br.*

This is a new officinal of the British Pharmacopœia, scarcely deserving the prominence thus given to it from anything yet known of its powers, especially when it is considered how unsparingly not a few of the older remedies, still thought by many practitioners to be efficacious, have been swept out of the officinal catalogue.

In the above process the bark is exhausted by water acidulated with sulphuric acid; lime is added to separate various inert matters, still leaving the acid in excess, as otherwise it might precipitate the bebeeria itself; the filtered liquor is treated with ammonia which throws down the bebeeria; the precipitate is exhausted by alcohol which dissolves the alkaloid; and the solution, having been concentrated, is treated with sulphuric acid so as to form the sulphate, which is obtained by evaporation to dryness. It is obvious that the salt of bebeeria thus obtained must be very impure, and among other substances probably contains a portion of sipeeria, another alkaloid of the bark. It is in dark-brown translucent scales, yellow when reduced to powder, of a strongly bitter taste, and soluble in water and alcohol. According to the Br. Pharmacopœia, "its watery solution gives with caustic soda a yellowish-white precipitate, which is dissolved by agitating the mixture with twice its volume of ether; and the ethereal solution, separated by a pipette, and evaporated, leaves a yellow translucent residue, entirely soluble in diluted acids." If the whole of the precipitate produced is dissolved by ether, it cannot contain sipeeria, which is insoluble in that menstruum. The officinal tests given are that it is "entirely destructible by heat," and that "water forms with it a clear brown solution."

Sulphate of bebeeria is a tonic, supposed to possess antiperiodic powers, and

has been given in intermittent fever and other periodical diseases. The dose is from two to five grains. (See *Nectandra*, in Part I.) W.

BISMUTHUM.

Preparations of Bismuth.

BISMUTHI SUBCARBONAS. *U. S.* *Subcarbonate of Bismuth.*

"Take of Bismuth, in pieces, *two troyounces;* Nitric Acid *eight troyounces and a half;* Water of Ammonia *five fluidounces;* Carbonate of Soda *ten troyounces;* Distilled Water *a sufficient quantity.* Mix four troyounces and a half of the Nitric Acid with four fluidounces of Distilled Water in a capacious glass vessel, and, having added the Bismuth, set the whole aside for twenty-four hours. Dilute the resulting solution with ten fluidounces of Distilled Water, stir it thoroughly, and, after twenty-four hours, filter through paper. To the filtered liquid, previously diluted with four pints of Distilled Water, slowly add the Water of Ammonia, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with two pints of Distilled Water, drain it again, and press out as much of the liquid as possible. Then place the precipitate in a proper vessel, add the remainder of the Nitric Acid, and heat nearly to the boiling point. When the solution has become cold, slowly add to it Distilled Water, with constant stirring, until the further addition of this liquid begins to produce a permanent milkiness. Then set the solution aside, and, at the end of twenty-four hours, filter through paper.

"Dissolve the Carbonate of Soda in twenty fluidounces of Distilled Water, with the aid of heat, and filter the solution through paper. To this, when cold, slowly add the solution of nitrate of bismuth, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with Distilled Water until the washings pass tasteless. Lastly, press the precipitate so as to free it as far as possible from water, dry it on bibulous paper with a gentle heat, and rub it into powder." *U. S.*

This preparation was first made officinal in the existing edition of the U. S. Pharmacopœia. As metallic bismuth generally contains arsenic, it is very important to provide that this should be left behind, in the processes for making its medicinal preparations. It is on this account that the present formula is so elaborate. The bismuth is first dissolved in nitric acid, a portion of which oxidizes the metal, with the evolution of nitrous vapours, while another portion combines with the oxide produced to form nitrate of bismuth. At the same time the arsenic is also oxidized at the expense of the nitric acid, and unites with a portion of the oxidized metal so as to generate the arseniate of bismuth. Both of these salts, therefore, are contained in the solution, which is very concentrated. Both have the property, when their solution is diluted with water, to separate into two salts, one an insoluble subsalt which is deposited, and the other a soluble supersalt which is held in solution. But the arseniate is more disposed to the change than the nitrate, and requires for the purpose a smaller amount of water of dilution. Hence, the first direction, after the metal has been dissolved, is to add a moderate quantity of distilled water, insufficient to cause the decomposition of the nitrate. From this diluted solution the insoluble subarseniate is slowly deposited, so as, in the course of twenty-four hours, to free it almost if not entirely from the poisonous metal. This is separated by filtration, and the solution is now diluted with a much larger quantity of distilled water, which causes a copious deposition of subnitrate of bismuth. But, in order not to waste the supernitrate remaining in solution, this is decomposed by ammonia, which takes most of the nitric acid, and precipitates the bismuth combined with the remainder in the form of subnitrate. The whole of the precipitated subnitrate, thus freed from

arsenic, is redissolved in nitric acid, and the solution of the nitrate now obtained, being diluted with just so much water as to produce a commencing precipitation of subnitrate, is freed by filtering from the small quantity formed, and slowly added to a solution of carbonate of soda. An interchange of principles takes place; nitrate of soda and carbonate of bismuth are formed, the former of which remains in solution, and the latter is deposited. This part of the process tends still further to get rid of the arsenic; for if any of the arsenic acid or arseniate of bismuth exist in the solution, the poisonous acid would combine with the soda, and thus forming a soluble salt, would be retained by the water. Nothing now remains but to wash, dry, and powder the precipitate.

Subcarbonate of bismuth may also be obtained free from arsenic by first purifying the bismuth, then dissolving it in three times its weight of nitric acid, evaporating the solution to two-thirds, adding it drop by drop to a solution of carbonate of soda, and carefully washing the precipitate. The bismuth may be freed from arsenic by two successive fusions with ten times its weight of nitre, or, as recommended by M. St. Pierre, by adding to it from 2·5 to 5 per cent. of zinc, and strongly heating the mixture for an hour in a crucible, with a piece of charcoal to prevent the oxidation of the zinc. Both the arsenic and zinc are driven off. (*Chem. News*, Jan. 16, 1861.) W.

Properties. Subcarbonate of bismuth is a white or yellowish-white powder, without odour or taste, and insoluble in water, whether pure or impregnated with carbonic acid. (*Berzelius.*) Its sp. gr. is about 4. It effervesces with acids, and, when exposed to heat, loses 9·5 per cent. of its weight (*U. S.*), in consequence of the escape of carbonic acid, and is converted into the anhydrous teroxide, of a light-yellow colour. When mixed with sulphuric acid, and subjected to Marsh's test, it should yield no arsenic, or merely a trace. Its formula is BiO_3,CO_2.

Medical Properties and Uses. This salt was brought into notice by M. Hannon, of Brussels, who recommends it as a substitute for the subnitrate. He considers it to act for the first few days of its employment as a sedative, and afterwards as a tonic. Like the subnitrate it is applicable to the treatment of gastralgia following the phlegmasias of the digestive organs, and attended with a red tongue, laborious digestion, acid eructations, and spasmodic vomitings. He conceives it, however, to have many advantages over the subnitrate, among which are its more ready tolerance by the stomach, its greater solubility in the gastric juice, its power to neutralize excess of acid in the stomach, and the want of any tendency to constipate. The dose is from 15 to 45 grains, given three times a day just before meals, and gradually increased. It may be taken in a little water. (*Ann. de Thérap.*, 1857, p. 214.) B.

BISMUTHI SUBNITRAS. *U. S.* Bismuthum Album. *Br. Subnitrate of Bismuth. White Bismuth.*

"Take of Bismuth, in pieces, *two troyounces;* Nitric Acid, Carbonate of Soda, each, *ten troyounces;* Water of Ammonia *six fluidounces;* Distilled Water *a sufficient quantity.* Mix four troyounces and a half of the Nitric Acid with four fluidounces of Distilled water, in a capacious glass vessel, and, having added the Bismuth, set the whole aside for twenty-four hours. Dilute the resulting solution with ten fluidounces of Distilled Water, stir it thoroughly, and, at the end of twenty-four hours, filter through paper.

"Dissolve the Carbonate of Soda in twenty fluidounces of Distilled Water with the aid of heat, and filter the solution through paper. To this, when cold, slowly add the solution of nitrate of bismuth, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with Distilled Water until the washings pass tasteless, and drain again as completely as possible. Then place the moist precipitate in a capacious vessel, gradually add the remainder of the Nitric Acid, and heat nearly to the boiling point.

When the solution has become cold, slowly add to it Distilled Water, with constant stirring, until the further addition of this liquid begins to produce a permanent milkiness. Then set the solution aside, and, at the end of twenty-four hours, filter through paper. To the filtered liquid, previously diluted with four pints of Distilled Water, slowly add the Water of Ammonia, with constant stirring. Transfer the whole to a strainer, and, after the precipitate has been drained, wash it with two pints of Distilled Water, drain it again, and press out as much of the liquid as possible. Lastly, dry it upon bibulous paper with a gentle heat, and rub it into powder." *U. S.*

"Take of Bismuth, in coarse powder, *two ounces* [avoirdupois]; Nitric Acid *two fluidounces and a half* [Imperial measure]; Distilled Water *one gallon* [Imp. meas.]. Dilute the Nitric Acid with three [fluid]ounces of the Water, and add the Bismuth in successive portions. When effervescence has ceased, apply for ten minutes a heat approaching that of ebullition, and decant the solution from any particles of metal which may remain undissolved. Evaporate the solution till it is reduced to two fluidounces, and pour it into half a gallon of the Water. When the precipitate which forms has subsided, decant the supernatant liquid, and agitate the sediment with the remainder of the Water. After two hours, again decant, and, having placed the product on a filter, dry it at a temperature of 212°." *Br.*

The U. S. process is new, the British that of the late Dublin Pharmacopœia. The alterations from the old process, in the former, were based upon the wish to get rid of any arsenic that might be present in the bismuth used. This is accomplished by first preparing the carbonate, by adding the nitric acid solution of bismuth to a solution of carbonate of soda in excess, whereby most of the arsenic is retained in the solution probably as arseniate of soda, while the insoluble carbonate is precipitated. This is dissolved, with the aid of heat, in nitric acid, so as to make a very concentrated solution of the nitrate, to which, when cold, just so much water is added as to begin to produce a permanent turbidness. The object of this is to allow any arsenic that may be still present to be deposited, which happens for reasons stated in explaining the process for procuring the subcarbonate. (See *page* 1024.) The deposited matter having been precipitated, only the pure nitrate remains in solution, which is made to yield the subnitrate by large dilution with water, and still more completely by the addition of ammonia.

In the British formula, the old method is pursued of simply dissolving the bismuth in nitric acid somewhat diluted, concentrating the solution, and precipitating by adding it to a large quantity of water. When bismuth is added to dilute nitric acid, red fumes are copiously given off, and the metal, oxidized by the decomposition of part of the nitric acid, is dissolved by the remainder so as to form a solution of the ternitrate of teroxide of bismuth. It is unnecessary to have the metal in powder; as it dissolves with great facility when added to the acid in fragments. When the solution is completed, the liquor should be added to the water, and not the water to the solution. Immediately on the contact of the solution with the water, four eqs. of the ternitrate are resolved into three eqs. of mononitrate of bismuth (subnitrate) which precipitates, and one eq. of the 9-nitrate which remains in solution. $4(BiO_3,3NO_5)=3(BiO_3,NO_5)$ and BiO_3, $9NO_5$. In order to have a smooth light powder, which is most esteemed, the precipitate should be well washed to remove every trace of free nitric acid, and dried as speedily as possible. In the use of this formula it is taken for granted that the bismuth has been ascertained to be free from arsenic; and, if it prove upon the application of Marsh's test to be otherwise, means should certainly be employed to purify before using it. Measures for this purpose have been mentioned under subcarbonate of bismuth. Should the subnitrate or subcarbonate be ascertained to contain arsenic, it may, as suggested by Dr. Herapath, be purified by boiling it with solution of caustic soda or potassa, twice successively, then th r-

oughly washing the residue, which will be yellow oxide of bismuth, dissolving it again in nitric acid, and precipitating by water as before. (*Chem. News*, Feb. 14, 1863, p. 77.) In the washing of subnitrate of bismuth, the salt is asserted to lose a portion of its nitric acid; and the change may be considerable, if the washing be persevered with so long as the liquid comes away in any degree acidulous. It has been ascertained by Julius Löwe that this effect may be avoided by washing with a very dilute solution of nitrate of ammonia, containing one part in 500 parts of water. (*Chem. Gaz.*, March 15, 1859, p. 119.)

Properties. Subnitrate of bismuth is a heavy powder, of a pure-white colour, a faintly sour smell and taste, and the property of reddening moistened litmus paper. It is slightly soluble in water, and readily so in the strong acids, from which it is precipitated by water. The fixed alkalies dissolve it sparingly, and ammonia more readily. It is darkened by hydrosulphuric acid gas, but not by exposure to light, unless it contains a little silver, or is subjected to the influence of organic matter. If it dissolves in nitric acid without effervescence, it contains no carbonate, and, if the nitric solution is not precipitated by dilute sulphuric acid, it is free from lead. It sometimes contains arsenic, which may be detected by acting on it with pure sulphuric acid, evaporating to dryness, dissolving in hot distilled water, and testing a part of the solution by Marsh's apparatus. By this method M. Lassaigne detected one-sixth of 1 per cent. of arsenic in a sample of subnitrate sold in Paris. The same chemist has found as much as 27 per cent. of chloride of bismuth in this preparation, when obtained by precipitating, with water, a solution of bismuth in a mixture of nitric and muriatic acids. The same impurity is introduced, to a small extent, by using common water containing chlorides; and subsulphate of bismuth renders the preparation impure, when the water used contains sulphate of lime. (*Journ. de Chim. Med.*, Mai, 1855, p. 276.) These facts show the necessity of using distilled water. As regards the origin of the chlorine sometimes existing in commercial subnitrate of bismuth, it is asserted by Mr. R. C. Tichborne to be a common practice with the manufacturer, in order to save the bismuth existing in the mother-liquor, after the deposition of the subnitrate, to precipitate it with chloride of sodium, thus obtaining an insoluble oxychloride of bismuth, which is then added to the previous product. (*Pharm. Journ.*, Feb. 1860, p. 413.) The new metal thallium is said to be present in most specimens of the pharmaceutical preparations of bismuth. For the modes of detecting and separating it, the reader is referred to the *Chemical News* (March 7, 1863, p. 109). Subnitrate of bismuth was called, by the earlier chemists, *magistery of bismuth*. It consists of one eq. of nitric acid 54, one of teroxide of bismuth 237, and one of water $9 = 300$. When heated to redness it loses 20 per cent. of its weight. *U. S.*

Medical Properties. Subnitrate of bismuth is antispasmodic, absorbent, and slightly sedative and astringent. When its use is too long continued it produces scorbutic symptoms, a proof that it is absorbed. It was first used as a medicine by Dr. Odier, of Geneva. It is principally employed in painful affections of the stomach, such as cardialgia, pyrosis, and gastrodynia, in spasmodic diseases, and in dysentery and diarrhœa. Rayer employed it with advantage in the diarrhœa of phthisis and typhus, and Aran recommended it in the obstinate form of the complaint which sometimes follows typhoid fever. It has been used also in dysentery. M. Monneret particularly insists upon the remarkable efficacy of the medicine, given in very large doses, in chronic gastro-intestinal affections, attended with diarrhœa; a plan of treatment which has been followed by several practitioners with advantage. M. Trousseau has successfully employed subnitrate of bismuth in the diarrhœa of children in the form of enema, in the dose of two scruples, mixed with thick flaxseed tea. M. Monneret uses it thus in much larger doses. He thinks that in diarrhœa its action is entirely local; but this view is combated by Dr. Lussanna, who believes that a part of the medicine enters the

circulation, though it never passes into the urine. Its use always blackens the stools. The dose of subnitrate of bismuth, usually prescribed, is five grains, gradually increased to fifteen, twice or thrice a day, given in pill, or mixed with sweetened water. Upon the plan of large doses, recommended by M. Monneret, from half an ounce to an ounce is given daily, in divided doses, in the diarrhœa of adults; from half a drachm to a drachm in that of infants; and from a drachm to two drachms in painful affections of the stomach. In these large doses the medicine is said to be perfectly safe; and yet Orfila mentions, as resulting from an overdose, gastric distress, nausea, vomiting, diarrhœa or constipation, colic, heat in the breast, slight rigors, vertigo, and drowsiness. These effects are to be combated by mucilaginous drinks, enemata, and emollient fomentations, and, in case of inflammation, by bleeding, both general and local. The contradictory statements as to the safety of the preparation can be explained only on the supposition that it is sometimes rendered poisonous by the presence of arsenic, chloride of bismuth, or free nitric acid; and a strong motive is thus furnished to the apothecary to prepare the medicine with the greatest care.

M. Monneret recommends the external use of subnitrate of bismuth as a drying application. In the treatment of ulcers, especially scrofulous ones, provided no risk would be incurred by stopping the discharge, he sprinkles the powder over the whole ulcerated surface. M. E. Caby has used it as a topical application in leucorrhœa, gonorrhœa, and gleet. When used in leucorrhœa, the entire surface of the vagina is dusted with the powder. The injection for gonorrhœa or gleet is made by mixing with water as much of the subnitrate as can be conveniently suspended. Three parts of the salt to twenty of water have been recommended. A portion of the mixture is injected thrice daily, and, each time, retained five minutes. The external use of subnitrate of bismuth is attended with no pain. (*Ranking's Abstract*, xx. 188.)* B.

* *Citrate of Bismuth and Ammonia. Liquor Bismuthi.* Though the insolubility of the officinal preparations of bismuth is probably one of the causes of their efficiency in certain diseases of the alimentary mucous membrane, enabling them by deposition on the surface to protect it against irritation from the contents of the stomach and bowels, yet a soluble form of the metal has been sought for, in the hope that it might, in this condition, operate on the *system* in smaller doses, and with greater certainty and efficiency. This want has been to some extent supplied by a secret preparation, made and sold by Mr. Schacht, of Clifton, England, which, under the name of *Liquor Bismuthi*, has, for the last five or six years, been used to a considerable extent in Great Britain. Mr. Ch. R. C. Tichborne, having analyzed the liquid, and found it to contain oxide of bismuth, ammonia, and citric acid, announced the discovery at a meeting of the Pharmaceutical Society, when Mr. Schacht, being present, acknowledged the correctness of the analysis, stating, at the same time, that he had never made a secret of the composition of his solution to medical practitioners, and that a fluidrachm of his liquid contained one grain of the teroxide. (*Pharm. Journ.*, Jan. 1864, p. 301.) A formula for the preparation was given by Mr. Tichborne, which, however, on repeated trial by Mr. N. Gray Bartlett, of Chicago, proved to be impracticable. After numerous experiments, Mr. Bartlett has succeeded in making a solution which has all the desired qualities, and a formula for which he has published in the *American Journal of Pharmacy* for January, 1865. He first prepares a *citrate of bismuth* by dissolving a *troy-ounce* of the subcarbonate of bismuth in 720 *grains* of nitric acid, diluting the solution after effervescence has ceased with *a fluidounce and a half* of distilled water gradually introduced, and then adding this solution, slowly and with constant stirring, to another solution made by dissolving 600 *grains* of citrate of potassa in *two pints* of distilled water. By an interchange of principles, nitrate of potassa and citrate of bismuth are formed, the latter of which, being insoluble, is precipitated, and is obtained by throwing the whole upon a filter, thoroughly washing the salt with distilled water, and then drying it on bibulous paper with a gentle heat. The next step is to prepare the *citrate of bismuth and ammonia*. This is done by rubbing the citrate of bismuth with sufficient distilled water to make a paste, and adding to this gradually, and with constant trituration, stronger water of ammonia until the citrate is dissolved, care being taken to avoid an excess of ammonia. The solution is now filtered, and spread on glass to dry. Citrate of bismuth and ammonia, thus obtained, is in fine, glossy, translucent, colourless scales, of a slightly acidulous, somewhat metallic, not disagreeable taste, very soluble in water, but not deliquescent, and of an acid reaction.

CADMIUM.

Preparation of Cadmium.

CADMII SULPHAS. *U. S. Sulphate of Cadmium.*

"Take of Cadmium, in small pieces, *a troyounce;* Nitric Acid *two troyounces* Carbonate of Soda *three troyounces;* Sulphuric Acid *four hundred and twenty grains;* Distilled Water *a sufficient quantity.* To the Cadmium and two fluidounces of Distilled Water, introduced into a glass vessel, add by degrees the Nitric Acid, and, when the action slackens, apply a gentle heat until the metal is dissolved. Filter the solution, and, having dissolved the Carbonate of Soda in six fluidounces of Distilled Water, mix the solutions thoroughly. Wash the precipitate obtained until the water passes tasteless, and dissolve it in the Sulphuric Acid, diluted with four fluidounces of Distilled Water. Then evaporate the solution to one-third, and set it aside to crystallize. Lastly, dry the crystals on bibulous paper." *U. S.*

A nitrate of cadmium is first formed, in consequence of the greater facility with which nitric acid acts upon that metal than sulphuric acid. The cadmium is oxidized at the expense of a part of the acid, with the production of hyponitric acid fumes, and the resulting oxide unites with the undecomposed part of the acid to form the nitrate. This is then decomposed in solution by carbonate of soda, with a mutual interchange of principles; the nitric acid of the nitrate of cadmium taking the soda of the carbonate, and forming nitrate of soda which is retained in solution, while the carbonic acid and oxide of cadmium combine to produce the insoluble carbonate of that metal, which is deposited. This, having been washed, is treated with dilute sulphuric acid, by which the carbonic acid is expelled, and the sulphate of cadmium generated in solution, from which it is obtained by concentration and crystallization.

Properties. Sulphate of cadmium crystallizes in oblique prisms with rhomboidal bases, which are transparent and colourless, and said to resemble those of sulphate of zinc. They have an astringent, slightly acidulous, and austere taste, effloresce on exposure to the air, and are very soluble in water. The solution, even though acidulated, gives with hydrosulphuric acid a yellow precipitate, becoming orange-yellow, of sulphuret of cadmium, which is dissolved by strong muriatic acid, but is insoluble in solutions of potassa or ammonia, and is thus readily distinguished from the sulphuret of arsenic. With hydrosulphate of ammonia it gives a yellow precipitate insoluble in an excess of the hydrosulphate. Ammonia produces a white precipitate, soluble in an excess of the precipitant; carbonate of ammonia a white one insoluble in an excess; ferrocyanide of potassium a white precipitate not dissolved by muriatic acid; and the ferridcyanide a brownish-yellow one soluble in a large excess of that acid. (*Brande & Taylor.*) By these tests sulphate of cadmium is distinguished as a salt of that metal. As a sulphate it is known by yielding a precipitate with chloride of barium not

From an analysis by Mr. Bartlett, it appears to consist of one eq. of teroxide of bismuth 237, one of ammonia 26, and one of citric acid 165, with 5 eqs. of water 45=473; and its formula is $BiO_3,NH_4O,C_{12}H_5O_{11}+5HO$.

There is no occasion for a permanent solution of this salt, as it may at any time be dissolved when wanted for use. But, as it is in the liquid form that it has obtained its present reputation, we give a formula for a permanent solution prepared by Mr. Bartlett. Dissolve 260 *grains* of citrate of bismuth and ammonia in *fourteen fluidounces* of distilled water, neutralize the solution with water of ammonia, and add *two fluidounces* of alcohol. The solution of the salt without addition is liable to spontaneous decomposition; but, in the opinion of Mr. Bartlett, it is completely protected by the ammonia and alcohol, so that in this state it will keep indefinitely. The dose of the solid citrate is two grains, that of the solution a fluidrachm. For further particulars in regard to the preparation of the salt and its solution, the reader is referred to Mr. Bartlett's paper in the *Am. Journ. of Pharm.* (Jan. 1865) already noticed.—*Note to the twelfth edition.*

soluble in nitric acid. Zinc precipitates cadmium in the metallic state from the solution. Cadmium suspended in a solution of sulphate of copper precipitates that metal, leaving sulphate of cadmium in solution; and this has been proposed as a method of obtaining the salt. The formula of sulphate of cadmium as commonly given is CdO,SO_3+4HO; but, according to M. de Hauer, it is said to have eight eqs. of water for every three of the salt, and its formula is $3(CdO,SO_3)+8HO$. (*Chem. News*, Nov. 29, 1862, p. 268.) W.

Medical Uses. Sulphate of cadmium is said to resemble sulphate of zinc as an astringent and emetic. Besides these properties, it possesses, according to M. Grimaud, valuable powers as a remedy in syphilis, rheumatism, and gout. As yet it has been used almost exclusively as an astringent and stimulating remedy in diseases of the eyes. In specks and opacities of the cornea, it has been employed successfully by both American and European surgeons. It is used either in solution, in the proportion of from half a grain to four grains to the fluidounce of distilled water, or in the form of ointment, made by mixing two grains with four scruples of fresh lard. M. Fronmüller has employed it, with excellent results, in specks of the cornea, dissolved in rose-water in the proportion of three grains to two fluidounces, conjoined with from half a fluidrachm to a fluidrachm and a half of wine of opium. We have had no experience with sulphate of cadmium as an internal remedy, and can give no authoritative statement as to the proper dose. Nor does this appear to have been well determined; for, while on the one hand we are told that it is ten times as strong as sulphate of zinc, on the other it is said to be used for the same purposes and in the same doses as that salt. (Bouchardat, *Ann. de Thérap.*, 1857, p. 231.) B.

CALX.

Preparations of Lime.

The liquid preparations of lime, *Liquor Calcis* and *Liquor Calcii Chloridi*, have, in conformity with the present edition of the U. S. Pharmacopœia, been transferred to the *Solutions*. (See *Liquores*.)

CALCIS CARBONAS PRÆCIPITATA. *U. S.*, *Br.* *Precipitated Carbonate of Lime.*

"Take of Solution of Chloride of Calcium *five pints and a half;* Carbonate of Soda *seventy-two troyounces;* Distilled Water *a sufficient quantity.* Dissolve the Carbonate of Soda in six pints of Distilled Water. Heat this solution and the Solution of Chloride of Calcium, separately, to the boiling point, and mix them. After the precipitate has subsided, separate it from the supernatant liquid by decantation, and wash it with boiling Distilled Water until the washings cease to be affected by a solution of nitrate of silver. Lastly, dry the precipitate on bibulous paper." *U. S.*

"Take of Chloride of Calcium *five ounces* [avoirdupois]; Carbonate of Soda *thirteen ounces* [avoird.]; Boiling Distilled Water *a sufficiency.* Dissolve the Chloride of Calcium and the Carbonate of Soda each in two pints [Imperial measure] of the Water; mix the two Solutions; and allow the precipitate to subside. Collect this on a calico filter, wash it with boiling Distilled Water, until the washings cease to give a precipitate with nitrate of silver, and dry the product at the temperature of 212°." *Br.*

These processes do not essentially differ. In each a mutual interchange of principles takes place, resulting in the production of chloride of sodium which remains in solution, and carbonate of lime which is deposited. Any peculiar advantage of the preparation must depend on the minute division of its particles. According to Dr. Bridges, this effect is best obtained by employing the solutions at the boiling temperature, a precaution which is observed in both the

present officinal processes. (*Amer. Journ. of Pharm.*, xvi. 163.) When properly made, it is a very pure carbonate of lime, in the form of a fine white powder, free from grittiness, insoluble in water, but wholly soluble in dilute muriatic acid with copious effervescence. These properties serve to distinguish it from sulphate of lime, with which it is sometimes adulterated, and which has even been sold for it. It is known to be a salt of lime by giving a copious white precipitate with oxalate of ammonia, when this is added to its solution in muriatic acid, previously neutralized by ammonia. It is dissolved by nitric acid, giving a clear solution, which if perfectly neutral, and boiled to drive off carbonic acid, gives no precipitate with saccharated solution of lime in excess, or with nitrate of silver, showing the absence of phosphates and chlorides. Its formula is CaO,CO_2, and equivalent number 50. For ordinary use, it probably has no such superiority over prepared chalk as to counterbalance its greater expensiveness. It is preferred by some to chalk in the preparation of tooth-powders. It is frequently sold in the shops under the name of *creta præcipitata*. The dose is from 10 to 40 grains or more. W.

CALCIS HYDRAS. *Br. Slaked Lime.*

"Take of Lime, recently burned, *two pounds* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Place the Lime in a metal pot, pour the Water upon it, and when vapour ceases to be disengaged cover the pot with its lid, and set it aside to cool. When its temperature has fallen to that of the atmosphere, remove its contents, pass the powder through an iron-wire sieve, and put it into a wide-mouthed bottle, which should be accurately closed with a well-fitted cork. Slaked Lime should be recently prepared." *Br.*

The U. S. Pharmacopœia has no separate formula for this preparation, but directs it to be made when at any time it may be wanted. In the process of slaking, water combines with lime to form a solid hydrate, with the evolution of much heat and the escape of white vapours, which consist of steam holding particles of lime in suspension. By union with water the lime acquires a whiter colour, and if previously in masses, becomes much softer, swelling up, and breaking into a coarse soft powder or friable lumps. When perfectly dry, it consists of one eq. of each of its constituents, with the formula CaO,HO. For the properties of lime the reader is referred to the head of *Calx*, in Part I. Hydrate of lime is used exclusively as a pharmaceutical agent.

CALCIS PHOSPHAS PRÆCIPITATA. *U. S., Br. Precipitated Phosphate of Lime.*

"Take of Bone, calcined to whiteness, and in fine powder, *four troyounces;* Muriatic Acid *eight troyounces;* Water of Ammonia *twelve fluidounces*, or *a sufficient quantity;* Distilled Water *a sufficient quantity.* Macerate the Bone with the Acid, diluted with a pint of Distilled Water, until it is dissolved, and filter the solution. Add another pint of Distilled Water, and then, gradually, Water of Ammonia until the liquid acquires an alkaline reaction. Mix the precipitate obtained, while yet in the state of magma, with twice its bulk of boiling Distilled Water, and pour the whole upon a strainer. Wash the precipitate with boiling Distilled Water until the washings cease to be affected by a solution of nitrate of silver, acidulated with nitric acid. Lastly, dry the precipitate with a gentle heat." *U. S.*

"Take of Bone Ash *four ounces* [avoirdupois]; Hydrochloric Acid *six fluidounces;* Distilled Water *two pints* [Imperial measure]; Solution of Ammonia *twelve fluidounces*, or *a sufficiency.* Digest the Bone Ash in the Hydrochloric

Acid diluted with a pint of Water, until it is dissolved. Filter the solution, if necessary; add the remainder of the Water, and afterwards the solution of Ammonia, until the mixture acquires an alkaline reaction; and, having collected the precipitate on a calico filter, wash it with boiling Distilled Water as long as the liquid which passes through occasions a precipitate, when dropped into the solution of nitrate of silver acidulated with nitric acid. Dry the washed product at a temperature not exceeding 212°." *Br.*

This preparation, whatever opinion may be entertained of its real powers, has been very properly introduced into the U. S. Pharmacopœia, as it is considerably used, and is by some much esteemed.

The muriatic acid dissolves the phosphate of lime of the bones, and lets it fall, on the addition of ammonia, in a state of minute division. The ablution is intended to free it from adhering muriate of ammonia. The salt thus obtained is, for the sake of distinction, called *bone phosphate of lime.* It is a white powder, without taste or smell, insoluble in water, but very soluble in nitric, muriatic, and acetic acids, from which it is precipitated unchanged by ammonia. By an intense heat it is fused, but is not otherwise changed. It consists, according to Mitscherlich, of one equivalent of phosphoric acid and three of lime.

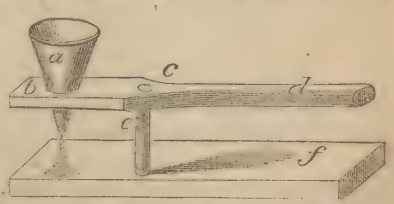
The chemical characteristics of bone phosphate of lime, besides those mentioned, are that with its solution in dilute nitric acid, oxalate of ammonia produces a white precipitate of oxalate of lime, and acetate of lead a white precipitate of phosphate of lead; and, if the nitric solution be neutralized as far as possible without causing a permanent precipitate of phosphate of lime, ammoniacal nitrate of silver throws down from it a lemon-yellow precipitate of phosphate of silver. (*Christison's Dispensatory.*)

Medical Uses. In the form of burnt hartshorn, phosphate of lime formerly enjoyed a brief popularity in the treatment of rickets and mollities ossium, in which its use seemed to be indicated upon obvious chemical grounds. It has recently been again brought into notice in consequence of the suggestion by Benecke (*London Lancet*, July, 1851), that, as it is essential in animals as well as plants to the formation of cells, it might be found useful in certain pathological states of the system characterized by defective nutrition, such as the scrofulous affections. Upon considerations of this kind, the late Dr. W. Stone, of New Orleans, was induced to employ it in cases of scrofulous ulceration, phthisis, &c., and with considerable supposed advantage. (See *St. Louis Med. and Surg. Journ.*, x. 38.) Subsequently, it has been used by other practitioners, and, in connection with other phosphates, as those of iron, soda, and potassa, has acquired no little reputation in different forms of scrofula and phthisis. When, however, it is considered that, in ordinary food, there is more of the phosphates than the system has need of, so that they are constantly escaping with the stools; and that in those very disorders in which they are supposed to be indicated they are not unfrequently in excess in the blood and urine, in consequence, probably, of the rapid disintegration of the tissues, it would seem doubtful whether the want, in scrofulous cases, is so much that of materials for cells as of due power to appropriate those materials. In the reported cases, the phosphate of lime has generally been administered in connection with cod-liver oil or other tonics; to which, there is reason to believe, any benefit experienced is more truly ascribable than to the phosphate. In two of Dr. Stone's cases the good effects began to be experienced at the period when they might have been expected from the oil alone. Phosphate of lime is thought to have proved useful by hastening the union of fractured bones; and M. Alphonse Milne-Edwards is said to have shown, by experiments upon dogs and rabbits, that, in these animals, the callus in fractured bones forms more quickly under its use than without it. (*Med. Times and Gaz.*, May, 1856, p. 489.) Its use in curvature of the spine and rickety affections in general has also been revived by M. Piorry and others. Though

insoluble in water, it is probably in general dissolved by the gastric liquids, in consequence of the acid present in them; and, if desirable, it may readily be administered in solution by the addition of one of the acids mentioned in the above account of its chemical properties. The dose is from ten to thirty grains.*

Off. Prep. Pulvis Antimonialis, *Br.* W.

CRETA PRÆPARATA. *U. S., Br. Prepared Chalk.*



"Take of Chalk *a convenient quantity.* Add a little water to the Chalk, and rub it into fine powder. Throw this into a large vessel nearly full of water, stir briskly, and, after a short interval, decant the supernatant liquor, while yet turbid, into another vessel. Treat the coarser particles of the Chalk, remaining in the first vessel, in a similar manner, and add the turbid liquid to that previously decanted. Lastly, set the liquid by that the powder may subside, and, having poured off the water, dry the powder." *U. S.*

"Take of Chalk *one pound* [avoirdupois]; Water *a sufficiency.* Reduce the Chalk to powder, and, having rubbed this in a mortar with as much Water as will give it the consistence of cream, fill the mortar with more Water, and stir well, giving the whole a circular motion. Allow the mixture to stand for fifteen seconds, and then decant the milky liquid into a large vessel. Rub what remains in the mortar, adding as much Water as was previously used, and, after allowing it to settle for fifteen seconds, again decant, and let this process be repeated several times, using, if necessary, additional Chalk. Transfer the fine sediment which subsides from the decanted liquids to a filter, and dry it at a temperature of 212°." *Br.*

The object of these processes is to reduce chalk to a very fine powder. The mineral, previously pulverized, should be rubbed with a little water upon a porphyry slab, by means of a muller of the same material. Having been thus very minutely divided, it is agitated with water, which upon standing a short time deposits the coarser particles, and, being then poured off, slowly lets fall the remainder in an impalpable state. The former part of the process is called *levigation*, the latter *elutriation*. The soft mass which remains after the decanting of the clear liquor, is made to fall upon an absorbent surface in small portions, which when dried have a conical shape.† Practically, prepared chalk is generally made on the large scale from *whiting* by the manufacturer. For the particulars of the process the reader is referred to the *Pharm. Journ.* (viii. 416).

* *Syrup of Phosphate of Lime.* Mr. T. S. Wiegand has proposed a syrup of phosphate of lime, to be made in the following manner. Take of the precipitated phosphate ℥j, muriatic acid f℥ss, water f℥vij, sugar q. s. Mix the phosphate with a fluidounce of the water; add the acid; filter the resulting solution; then add the remainder of the water, and enough sugar to make twelve fluidounces of syrup; and, finally, strain. (*Am. Journ. of Pharm.*, xxvi. 297.)—*Note to the eleventh edition.*

† Several insoluble substances, besides chalk, are brought habitually into the form of small cones, such as prepared oyster-shell, phosphate of lime, rust of iron, subnitrate of bismuth, &c. The mode by which this is effected is by the use of a simple implement, consisting of a funnel of tinned-iron, with the neck removed (*a*), fixed at the expanded extremity (*b*) of a piece of wood about a foot long (*c*), having its other end in the form of a handle (*d*), with a stout piece of wood about 4 inches long (*e*), attached perpendicularly to the lower side of it, so as to serve as a support when fixed in a sockét. The material to be shaped is introduced in a very soft, almost diffluent state into the funnel, and the instrument, then raised in the hand by the handle, is brought down so that its support shall strike with a gentle shock against a flat surface of chalk stone (*f*), and these little shocks are rapidly repeated. At each one of them a small portion of the soft mass escapes from the mouth of the funnel, and falls on the stone, where it hardens into the shape of a cone; the chalk serving to absorb the moisture rapidly, and thus enabling it quickly to solidify.—*Note to the twelfth edition.*

Medical Properties and Uses. This is the only form in which chalk is used in medicine. It is an excellent antacid; and, as the salts which it forms in the stomach and bowels, if not astringent, are at least not purgative, it is admirably adapted to diarrhœa accompanied with acidity. It is also sometimes used in acidity of stomach attending dyspepsia and gout, when a laxative effect is to be avoided; is one of the best antidotes for oxalic acid; and has been recommended in rachitis. In scrofulous affections it may sometimes do good by forming soluble salts with acid in the primæ viæ, and thus finding an entrance into the blood-vessels. It is frequently employed as an application to burns and ulcers, which it moderately stimulates, while it absorbs the ichorous discharge, and thus prevents it from irritating the diseased surface, or the sound skin. It is given internally in the form of powder, or suspended in water by the intervention of gum arabic and sugar. (See *Mistura Cretæ.*) It is better fitted for the chalk mixture than the precipitated carbonate of lime, in consequence of its more impalpable character. The dose is from ten to forty grains or more.

Pharm. Uses. In preparing Acidum Citricum, *Br.;* Acidum Tartaricum, *Br.;* Zinci Chloridum, *U. S.*

Off. Prep. Hydrargyrum cum Cretâ; Mistura Cretæ; Pulvis Cretæ Aromaticus, *Br.;* Trochisci Cretæ, *U. S.* W.

TESTA PRÆPARATA. *U. S. Prepared Oyster-shell.*

"Take of Oyster-shell *a convenient quantity.* Free the Oyster-shell from extraneous matter, wash it with boiling water, and, having reduced it to a fine powder, treat this in the manner directed for Prepared Chalk." *U. S.*

Prepared oyster-shell differs from prepared chalk in containing animal matter, which, being very intimately blended with the carbonate of lime, is supposed by some physicians to render the preparation more acceptable to a delicate stomach. It is given as an antacid in diarrhœa, in the dose of from ten to forty grains or more, frequently repeated. A preparation has been introduced, within a few years, into use in this country, under the name of *Castillon's powders*, consisting of sago, salep, and tragacanth, each, in powder, *a drachm*, prepared oyster-shell *a scruple*, and sufficient cochineal to give colour to the mixture. A drachm of this is boiled in a pint of milk, and the decoction used *ad libitum* as a diet in chronic bowel affections. W.

CARBO.

Preparation of Charcoal.

CARBO ANIMALIS PURIFICATUS. *U. S., Br. Purified Animal Charcoal.*

"Take of Animal Charcoal, in fine powder, Muriatic Acid, each, *twelve troy-ounces;* Water *twelve fluidounces.* Pour the Muriatic Acid, previously mixed with the Water, gradually upon the Charcoal, and digest with a gentle heat for two days, occasionally stirring the mixture. Having allowed the undissolved portion to subside, pour off the supernatant liquid, wash the Charcoal frequently with water until the washings cease to afford a precipitate with the nitrate of silver, and dry it." *U. S.*

"Take of Bone Black *sixteen ounces* [avoirdupois]; Hydrochloric Acid *ten fluidounces;* Distilled Water *a sufficiency.* Mix the Hydrochloric Acid with a pint of the Water, and add the Bone Black, stirring occasionally. Digest at a moderate heat for two days, agitating from time to time; collect the undissolved charcoal on a calico filter, and wash with Distilled Water till what passes through gives scarcely any precipitate with nitrate of silver. Dry the charcoal, and then heat it to redness in a covered crucible." *Br.*

Animal charcoal, as it is made by charring bones, necessarily contains bone-phosphate and carbonate of lime, the presence of which does no harm in some

decolorizing operations; but, in delicate chemical processes, these salts may be dissolved or decomposed, and thus become a source of impurity. It is on this account that animal charcoal requires to be purified from its calcareous salts; and this is accomplished by dilute muriatic acid, which dissolves the phosphate and decomposes the carbonate. According to Dr. Stenhouse, aluminized vegetable charcoal may be substituted for purified animal charcoal, and is equally efficacious as a decolorizer. (See *page* 215.)

Purified animal charcoal is a dark brownish-black powder. If it contain carbonate of lime, muriatic acid will cause effervescence, and the solution obtained will give a precipitate with carbonate of ammonia; and if phosphate or sulphate of lime be present, the acid will dissolve the salt, and yield it as a precipitate on the addition of ammonia. In the Br. Pharmacopœia, it is stated that, when burned at a high temperature, with free access of air, it leaves scarcely any residue.

It has been shown by Mr. Robert Warington that bitter vegetable substances, including the organic alkalies, are removed from solution by passing through *purified* animal charcoal, especially when the action is assisted by heat. M. Weppen finds that a similar effect is produced by it in removing resins from tinctures, tannic acid and bitter principles from astringent and bitter infusions, and certain metallic salts from their solutions. Purified animal charcoal, thus employed, has been resorted to by M. Lebourdais as an agent for obtaining the active principles of plants. A decoction or infusion of the plant is either boiled with or filtered through the charcoal, which takes up, more or less completely, the bitter and colouring principles. The charcoal, after having been washed and dried, is treated with boiling alcohol, which dissolves the principles taken up. Finally, the alcohol is distilled off, and the principles are obtained in a separate state. In this way digitaline, ilicin, scillitin, colombin, colocynthin, arnicina, strychnia, quinia, and other principles have been obtained by M. Lebourdais. (*Chem. Gaz.*, Nov. 15, 1848.) In relation to the method of M. Lebourdais, see a paper by Mr. J. S. Cobb, in the *Am. Journ of Pharm.* for July, 1851, from the London *Pharmaceutical Journal.* Dr. A. B. Garrod has proposed purified animal charcoal as an antidote to vegetable and animal poisons, with which it appears to combine. According to his experiments, common bone-black has not one-fifth of the power possessed by the purified substance; and vegetable charcoal and lampblack are nearly or quite useless. The amount of the antidote proposed by Dr. Garrod is half an ounce for each grain of a vegetable organic alkali. Dr. Alfred Taylor deems the results of Dr. Garrod inconclusive. Prof. B. H. Rand, of this city, has made some interesting observations in relation to the antidotal powers of purified animal charcoal, and has proved that poisonous doses of the strongest vegetable poisons may be swallowed with impunity, if mixed with that substance. (*Med. Exam.*, Sept. 1848.)*

* *Revivification of Animal Charcoal.* To the large manufacturing chemist, and in a less degree to the pharmaceutist, it is an object of some importance to revivify the animal charcoal which has lost its absorbent property, and thus to fit it for future use. This has been done by exposing it to an intense heat, so as to decompose all the organic, and drive off all the volatile principles it may have absorbed; but this will not deprive it of fixed inorganic substances which may contaminate it. Messrs. Leplay and Cusinier, in a paper on the use of animal charcoal in the refining of sugar, offer certain principles and suggest certain practical processes in reference to this agent, which are of general interest, and which have appeared to us to merit a notice here. The absorbing powers of animal charcoal are different for different substances, and do not become exhausted simultaneously. For its revivification after use, different measures are required in accordance with the degree to which its powers may have been lost. There are, indeed, means of increasing these absorbent powers even beyond the degree to which they may have been originally possessed. None of these revivifying measures require a heat above 212°. The following are the practical principles. 1. When animal charcoal is employed in filtering, its first series of absorbing powers are exhausted at furthest in four hours. These are such as affect "viscid, nitrogeneous, ammoniacal, sapid, and odorous matters." In regard to these the original power

In using animal charcoal for decolorizing active vegetable principles, great caution should be observed, as much loss is often incurred by the absorption of those principles by the charcoal.

Pharm. Uses. In preparing Acidum Gallicum, *U. S.;* Atropia, *Br.;* Digitalinum, *Br.;* Morphiæ Hydrochloras, *Br.;* Santoninum, *Br.;* Strychnia, *U. S.;* and Veratria. B.

CATAPLASMATA.

Cataplasms.

Cataplasms or *poultices* are moist substances intended for external application, of such a consistence as to accommodate themselves accurately to the surface to which they are applied, without being so liquid as to spread over the neighbouring parts, or so tenacious as to adhere firmly to the skin. As they are in this country seldom made by the apothecary, they were not deemed by the compilers of the U. S. Pharmacopœia proper objects for officinal direction. The ounce used in the following processes is the avoirdupois. W.

CATAPLASMA CARBONIS. *Br. Charcoal Poultice.*

"Take of Wood Charcoal, in powder, *half an ounce;* Bread *two ounces;* Linseed Meal *one ounce and a half;* Boiling Water *ten fluidounces.* Macerate the Bread in the Water for a short time near the fire, then mix, and add the Linseed Meal gradually, stirring the ingredients, so that a soft poultice may be formed. Mix with this half the Charcoal, and sprinkle the remainder on the surface of the poultice." *Br.*

Charcoal, recently prepared, has the property of absorbing those principles upon which the offensive odour of putrefying animal substances depends. In the form of poultice, it is an excellent application to foul and gangrenous ulcers, correcting their fetor, and improving the condition of the sore. It should be frequently renewed. W.

CATAPLASMA CONII. *Br. Hemlock Poultice.*

"Take of Hemlock Leaf, in powder, *one ounce;* Linseed Meal *three ounces;* Boiling Water *ten fluidounces.* Mix the Hemlock and Linseed Meal, and add them to the water gradually, constantly stirring." *Br.*

This cataplasm may be advantageously employed as an anodyne application to cancerous, scrofulous, syphilitic, and other painful ulcers; but its liability to produce narcotic effects, in consequence of the absorption of the active principle of the hemlock, should not be overlooked. W.

CATAPLASMA FERMENTI. *Br. Yeast Poultice.*

"Take of Beer Yeast *six fluidounces;* Flour *fourteen ounces;* Water,

is entirely restored by passing a current of steam through the granulated animal charcoal contained in the filter; and it can be restored indefinitely. 2. The second series of absorbing powers concern free alkalies, as potash, soda, lime, and their salts; and require a much longer time for their exhaustion, to the extent of six or eight times the period required for the first series. These powers are revived by pouring muriatic acid largely diluted with water upon the charcoal in the filter, and afterwards by prolonged washing with water. 3. The third series of absorbing powers embrace colouring principles, and continue thirty or forty times longer than the first. For the restoration of these powers the measure deemed most efficient is washing with weak boiling solutions of the caustic alkalies. All these measures may be applied to the charcoal still contained in the filter, or removed to a special apparatus for the purpose. 4. These methods restore the original properties. To give additional absorbent powers, a solution of biphosphate of lime is poured upon the animal charcoal still containing its original tribasic phosphate. When these salts meet, a new phosphate is produced with two eqs. of base, which is insoluble in water, has no acid reaction, and possesses very energetic powers of absorption. (See *Am. Journ. of Pharm.*, Nov. 1862, p. 552.)—*Note to the twelfth edition.*

heated to 100°, *six fluidounces.* Mix the Yeast with the Water, and stir in the Flour. Place the mass near the fire till it rises." *Br.*

By exposing a mixture of yeast and flour to a gentle heat, fermentation takes place, and carbonic acid gas is extricated, which causes the mixture to swell, and is the source of its peculiar virtues. The yeast cataplasm is gently stimulant, and is sometimes applied with benefit to foul and gangrenous ulcers, the fetor of which it corrects, while it is supposed to hasten the separation of the slough. The carbonic acid may also act as an anæsthetic agent. W.

CATAPLASMA LINI. *Br. Linseed Poultice.*

"Take of Linseed Meal *four ounces;* Olive Oil *half a fluidounce;* Boiling Water *ten fluidounces.* Mix the Linseed Meal with the Oil, then add the Water gradually, constantly stirring." *Br.*

The flaxseed meal which remains after the expression of the oil is here employed; but that which has not been submitted to pressure is decidedly preferable, and answers an excellent purpose when mixed with boiling water, without other addition. Fresh lard or olive oil, spread upon the surface of the poultice, serves to prevent its adhesion to the skin, and to preserve its softness.

The use of this and other emollient cataplasms is to relieve inflammation, or to promote suppuration. They act mainly by the sedative influence of their moisture, and by excluding the air. The one most extensively employed, perhaps because its materials are always at hand, is that prepared by heating together milk and the crumb of bread. The milk should be quite sweet, and fresh lard should be incorporated with the poultice. Mush made with the meal of Indian corn also forms an excellent emollient cataplasm. W.

CATAPLASMA SINAPIS. *Br. Mustard Poultice.*

"Take of Mustard, in powder, Linseed Meal, each, *two ounces and a half;* Boiling Water *ten fluidounces.* Mix gradually the Linseed Meal with the Water, and add the Mustard, constantly stirring." *Br.*

The simplest and most effectual mode of preparing a mustard poultice, is to mix the powdered mustard of the shops with a sufficient quantity of warm water to give it a due consistence. When a weaker preparation is required, an equal portion or more of rye or wheat flour should be added. Vinegar never increases its efficiency, and, in the case of the black mustard seed, has been ascertained by MM. Trousseau and Blanc to diminish its rubefacient power. The same may be said of alcohol. A boiling temperature is also injurious by interfering with the development of the volatile oil or acrid principle. (See *Sinapis.*)

These poultices are frequently called *sinapisms.* They are powerfully rubefacient, exciting a sense of warmth in a few minutes, and usually becoming insupportably painful in less than an hour. When removed they leave the surface intensely red and burning; and the inflammation frequently terminates in desquamation, or even blistering if the application be too long continued. Obstinate ulcers and gangrene also sometimes result from the protracted action of mustard, especially on parts possessed of little vitality. As a general rule, the poultice should be removed when the patient complains much of pain; and in cases of insensibility should not, unless greatly diluted, be allowed to remain longer than one, or at most two hours; as violent inflammation, followed by obstinate ulceration, is apt to take place upon the occurrence of reaction. In children particular care is necessary to avoid this result. The poultice should be thickly spread on linen, and may be covered with gauze or unsized paper in order to prevent its adhesion to the skin. If hairs are present they should be removed by the razor. Sinapisms may be employed in all cases in which it is desirable to produce a speedy and powerful rubefacient impression. W.

CATAPLASMA SODÆ CHLORINATÆ. *Br. Chlorine Poultice.*

"Take of Solution of Chlorinated Soda *two fluidounces;* Linseed Meal

four ounces; Boiling Water *eight fluidounces.* Add the Linseed Meal gradually to the Water, stirring constantly; then mix in the Solution of Chlorinated Soda." *Br.*

This is an excellent application to sloughing and other fetid ulcers, to correct the smell, and afford a moderate stimulation. W.

CERATA.

Cerates.

These are unctuous substances consisting of oil or lard, mixed with wax, spermaceti, or resin, to which various medicaments are frequently added. Their consistence, which is intermediate between that of ointments and of plasters, is such that they may be spread at ordinary temperatures upon linen or leather, by means of a spatula, and do not melt or run when applied to the skin. In preparing them, care should usually be taken to select the oil or lard perfectly free from rancidity. The liquefaction should be effected by a very gentle heat, which may be applied by means of a water-bath; and during the refrigeration the mixture should be well stirred, and the portions which solidify on the sides of the vessel should be made to mix again with the liquid portion, until the whole assumes the proper consistence. When a large quantity is prepared, the mortar or other vessel into which the mixture may be poured for cooling, should be previously heated by means of boiling water. It has been proposed to substitute paraffin for wax in the preparation of the cerates; but there has yet been too little trial of it to justify a decision upon its merits. It is, we think, unfortunate that this class of preparations has been abandoned in the British Pharmacopœia; the several cerates having been rejected, or transferred to the class of Ointments. Independently of the connection between the name and one of the characteristic constituents of the cerates, there is a ground of difference between them and the ointments in their consistence; that of the cerates being such as to render them especially suitable for spreading on linen, while that of ointments is peculiarly adapted to inunction. W.

CERATUM ADIPIS. *U. S.* Ceratum Simplex. *U. S.* 1850. *Cerate of Lard. Simple Cerate.*

"Take of Lard *eight troyounces;* White Wax *four troyounces.* Melt them together, and stir the mixture constantly until cool." *U. S.*

We regret the loss of the old name of simple cerate, which always seemed to us very appropriate. Wax was the essential ingredient, while the place of lard might be supplied by olive or almond oil, or any bland fatty matter of a very soft or liquid consistence. Lard, however, is, we think, preferable to olive oil, as it may always be had perfectly sweet, and is the mildest application which can be made to irritated surfaces. In the preparation of this cerate, peculiar care should be taken that the oleaginous ingredient be entirely free from rancidity, and that the heat employed be not sufficient to produce the slightest decomposition; for the value of the preparation depends on its perfect blandness. To avoid change, it should be put up in small jars, and covered closely with tin foil so as to exclude the air. It is used for dressing blisters, wounds, &c., in all cases in which the object is to prevent the contact of air and preserve the moisture of the part, and at the same time to avoid all irritation. It is sometimes improperly employed as the vehicle of substances to be applied by inunction. For this purpose lard should be used in winter, and simple ointment in summer; the cerate having too firm a consistence. W.

CERATUM CANTHARIDIS. *U. S.* Emplastrum Cantharidis. *Br. Cerate of Cantharides. Blistering Cerate. Cerate of Spanish Flies. Cantharides Plaster.*

"Take of Cantharides, in very fine powder, *twelve troyounces;* Yellow Wax, Resin, each, *seven troyounces;* Lard *ten troyounces.* To the Wax, Resin, and Lard, previously melted together and strained through muslin, add the Cantharides, and, by means of a water-bath, keep the mixture in a liquid state for half an hour, stirring occasionally; then remove it from the water-bath, and stir it constantly until cool." *U. S.*

The *British Pharmacopœia* directs of Cantharides, in very fine powder, *twelve ounces* (avoirdupois); Yellow Wax, and Prepared Suet, each, *seven ounces and a half;* Resin *three ounces*, and Prepared Lard *six ounces;* melts the Wax, Suet, and Lard together by a steam or water-bath, adds the Resin previously melted; then removes from the bath, and, a little before they solidify, sprinkles in the cantharides, and mixes by stirring briskly.

This is the common *blistering plaster* of the shops. As it can be readily spread without the aid of heat, it is properly a cerate, and is, therefore, correctly named in the U. S. Pharmacopœia. It is essentially the same as prepared by the two processes; though the U. S. formula has a decided advantage over the British, in keeping the mixture of the flies and the other ingredients for some time at an elevated temperature, while, in the latter, they are not mixed with the fatty matters until these begin to become cool. Care was formerly considered requisite, in making the cerate, not to injure the flies by heat. It was, therefore, recommended that they should not be added to the other ingredients until immediately before these begin to stiffen, after having been removed from the fire; and this direction is still continued in the British formula. But from the experiments of Mr. Donovan (*Dublin Med. Press*, Aug. 1840), and those of Professor Procter (*Am. Journ. of Pharm.*, xiii. 302, and xxiv. 296), it may be inferred that the vesicating principle of Spanish flies is not injured or dissipated by a heat under 300° F., and that an elevated temperature, instead of being hurtful, is positively advantageous in the preparation of the cerate. The cantharidin is thus more thoroughly dissolved by the oleaginous matter, and consequently brought more efficiently into contact with the skin, than when retained in the interior of the tissue of the fly. Another advantage, stated by Donovan, is that the moisture, usually existing to a certain extent in all the ingredients of the cerate, is thus dissipated, and the preparation is less apt to become mouldy, or otherwise to undergo decomposition. Instead, therefore, of waiting until the melted wax, resin, and lard begin to stiffen, it is better to add the powder before the vessel is removed from the fire. Mr. Donovan recommends that, as soon as the other ingredients are melted, the powdered flies should be added, and the mixture stirred until the heat is shown by a thermometer to have risen to 250°, when the vessel is to be removed from the fire, and the mixture stirred constantly until cool. At the heat mentioned, ebullition takes place in consequence of the escape of the moisture contained in the materials. In the cerate thus prepared, the active matter has been dissolved by the lard, and the powder may be separated, if deemed advisable, by straining the mixture before it solidifies. Care should be taken that the temperature be not so high as to decompose the ingredients; and it would be better to keep it within 212° by means of a water-bath, than to incur any risk from its excess. Violent irritation and even vesication of the face of the operator are stated to have resulted from exposure to the vapours of the liquid, at a temperature of 250°. (*Pharm. Journ.*, ii. 391.) From an experiment, however, of Prof. Procter, it appears that, though cantharidin begins to volatilize slightly at 250°, and rapidly rises in vapour and sublimes at from 402° to 412°, yet it is not decomposed unless by increasing the heat considerably above the last mentioned point. (*Am. Journ. of Pharm.*, xxiv. 296 and 298.) It is desirable that the flies should be very finely pulverized. Powdered euphorbium is said to be sometimes fraudulently added.

The cerate will always raise a blister in ordinary conditions of the system, if

the flies are good, and not injured in the preparation. It should be spread on soft leather, though linen or even paper will answer the purpose when that is not to be had. An elegant mode of preparing it for use is to spread a piece of leather, of a proper size, first with adhesive plaster, and afterwards with the cerate, leaving a margin of the former uncovered, in order that it may adhere to the skin. Heat is not requisite, and should not be employed in spreading the cerate. Some sprinkle powdered flies upon the surface of the plaster, press them lightly with a roller, and then shake off the portion which has not adhered; but, if the flies originally employed were good, this addition is superfluous. Prof. Procter is in the habit of applying over the surface with a brush an ethereal tincture of cantharides, which leaves a thin coating of extract, and renders the preparation more certain.

Upon the application of the plaster, the skin should be moistened with warm vinegar or other liquid; and a good rule is to cover the surface of the plaster closely with very thin gauze or unsized paper, which prevents any of the cerate from adhering to the cuticle, and is thought by some to diminish its liability to occasion strangury. In adults, when the full action of the flies is desired, and the object is to produce a permanent effect, the application should be continued for twelve hours, and on the scalp for twenty-four hours. In very delicate persons, however, or those subject to strangury, or upon parts of a loose texture, or when the object is merely to produce a blister to be healed as quickly as possible, the plaster should remain no longer than is necessary for the production of full redness of the skin, which generally occurs in five or six hours, or even in a shorter time. It should then be removed, and followed by a bread and milk poultice, or some other emollient dressing, under which the cuticle rises, and a full blister is usually produced. By this management the patient will generally escape strangury, and the blister will very quickly heal after the discharge of the serum.* In young children, cantharides sometimes produce alarming and even fatal ulceration, if too long applied. From two to four hours are usually sufficient for any desirable purpose. When the head, or other very hairy part is to be blistered, an interval of ten or twelve hours should, if possible, be allowed between the shaving of the part and the application of the plaster; so that the abrasions may heal, and some impediment be offered to the absorption of the flies. After the blister has been formed, it should be opened at the most depending parts, and, the cuticle being allowed to remain, should be dressed with simple cerate; but, if it be desirable to maintain the discharge for a short time, resin cerate should be used, and the cuticle removed if it can be done without inconvenience. When it is wished that the blistered surface should heal as soon as possible, and with the least inconvenience to the patient, Dr. Maclagan recommends a dressing of cotton wadding; an emollient poultice being first applied for two hours after the removal of the blistering cerate, the cuticle then cut, and the surface afterwards covered with the cotton, with its raw surface next the skin. Should the dressing become soaked, so much of the cotton may be removed as can be done without disturbing the cuticle, and a new batch applied. The cotton is to be allowed to remain until the old cuticle spontaneously

* The late Dr. M. B. Smith, of Philadelphia, informed us that he had frequently employed uva ursi, as a preventive of strangury from blisters, and had never found it to fail. He gave a small wineglassful of the officinal decoction (see *Decoctum Uvæ Ursi*) every hour, commencing two hours after the application of the blister. Camphor is sometimes incorporated with the blistering cerate to prevent strangury, though with doubtful effect. A plan proposed by M. Vée is to spread over the surface of the plaster, when ready for delivery, by means of the finger, a saturated solution of camphor in ether. The ether evaporates, leaving a thin coating of camphor uniformly diffused. (*Journ. de Pharm.*, 3e *sér.*, viii. 68.) The late Dr. Joseph Hartshorne, of Philadelphia, was in the habit, in cases where he apprehended strangury, of directing four grains of opium and twenty of camphor to be mixed with the cerate of a blister of large size, and experienced the happiest effects from the addition.

separates. The effects of an issue may be obtained by employing savine ointment, or the ointment of Spanish flies, as a dressing. If much inflammation take place in the blistered surface, it may be relieved by emollient poultices, or weak lead-water. Where there is an obstinate indisposition to heal, we have found nothing so effectual as the cerate of subacetate of lead, mixed with an equal weight of simple cerate. When deep and extensive ulceration occurs in consequence of general debility, bark or sulphate of quinia should be used, with nutritious aliment.

Various preparations of cantharides have been proposed and employed as substitutes for the cerate. They consist for the most part of cantharidin, more or less pure, either dissolved in olive oil and applied to the skin by means of a piece of paper saturated with it, or incorporated with wax and spread in a very thin layer upon fine waxed cloth, silk, or paper, constituting the *blistering cloth*, *blistering paper*, *vesicating taffetas*, *&c.*, of the shops. The advantages of these preparations are that they occupy less space, are more portable, and, being very pliable, are more easily adapted to irregularities of the surface. Absolutely pure cantharidin is expensive and not requisite; as extracts of cantharides, made with ether, alcohol, or boiling water, will answer every purpose. Henry and Guibourt give the following formula. Digest powdered cantharides in ether, distil off the ether, evaporate the residue by means of a salt-water bath, until ebullition ceases, melt the oily mass which remains with twice its weight of wax, and spread the mixture upon waxed cloth. The *waxed cloth* may be prepared by spreading upon linen or muslin a mixture composed of 8 parts of white wax, 4 of olive oil, and 1 of turpentine, melted together. An extract of cantharides, of a buttery consistence, said to act very efficiently when applied by means of paper greased with it, is prepared by digesting 4 parts of flies with 1 part of strong acetic acid, and 16 of alcohol, straining, filtering, and evaporating at a moderate heat. A preparation which received the favourable report of a committee of the Society of Pharmacy, at Paris, is the following, proposed by M. Dubuisson. Four parts of a hydro-alcoholic extract of the flies, made by maceration, is mixed with an aqueous solution of one part of pure gelatin, so as to obtain a solution of suitable consistence, which is then applied upon a piece of extended waxed cloth, care being taken that the brush should always have the same direction. When the first layer has dried, a second and a third are to be applied in the same manner. The gelatin renders the cloth more adhesive and less deliquescent. The hydro-alcoholic extract is preferred to the alcoholic, because it contains less of the green oil, which does not readily mix with the other ingredients. The committee, however, preferred the aqueous extract, as cheaper and more active. This taffeta has been tried, and found to raise blisters in four hours. (*Journ. de Pharm.*, 3e *sér.*, viii. 67.) A strong decoction of the flies in olive oil, applied by means of paper, would probably answer a similar purpose with these more elaborate preparations; but none of them is likely to supersede the officinal cerate. For very speedy vesication, an infusion of the flies in strong acetic acid is sometimes employed. A preparation, called *cantharidal collodion*, has within a few years been introduced into use, and has acquired so great a popularity with the profession that it was deemed proper, at the recent revision of the Pharmacopœia, to introduce a formula for its preparation. (See *Collodium cum Cantharide.*)

It is said that the flies, by ebullition with water, are deprived of their property of producing strangury, while their vesicating powers remain unaltered. (*Paris's Pharmacologia.*) Dr. Theophilus Beesley, of Philadelphia, was in the habit of employing a cerate made with cantharides prepared in this manner, and never knew it to produce strangury in more than two or three instances. (*Journ. of the Phil. Col. of Pharm.*, iv. 185.) In a letter addressed to one of the authors by Dr. James Couper, of Newcastle, Delaware, a similar method of pre-

paring the flies is recommended as an expedient against strangury, both from his own experience, and that of the late Dr. Groom, of Elkton, Maryland, from whom he derived his knowledge of the plan. Yet there can be no doubt that boiling water extracts cantharidin from the flies; and the cerate made as here recommended must be weaker in the blistering principle than the officinal.

Off. Prep. Emplastrum Picis cum Cantharide, *U. S.* W.

CERATUM CETACEI. *U. S. Spermaceti Cerate.*

"Take of Spermaceti *a troyounce;* White Wax *three troyounces;* Olive Oil *five troyounces.* Melt together the Spermaceti and Wax; then add the Oil previously heated, and stir the mixture constantly until cool." *U. S.*

The direction to heat the oil before adding it to the other ingredients is important. If added cold, it is apt to produce an irregular congelation of the wax and spermaceti, and thus to render the preparation lumpy. This cerate is employed as a dressing for blisters, excoriated surfaces, and wounds, and as the basis of more active preparations. When the ingredients are pure and sweet, it is perfectly free from irritating properties. From experiments made by Mr. J. B. Barnes, London, it appears that this cerate keeps much better when made of unbleached materials, than when prepared with olive oil and wax previously bleached. (*Pharm. Journ.*, Jan. 1861, p. 352.) W.

CERATUM EXTRACTI CANTHARIDIS. *U. S. Cerate of Extract of Cantharides.*

"Take of Cantharides, in fine powder, *five troyounces;* Stronger Alcohol *two pints and a half*, or *a sufficient quantity;* Resin *three troyounces;* Yellow Wax *six troyounces;* Lard *seven troyounces.* Moisten the Cantharides with Stronger Alcohol, pack them in a cylindrical percolator, and gradually pour on Stronger Alcohol until the liquid passes nearly colourless. Evaporate the filtered liquid, by means of a water-bath, to the consistence of a soft extract. Mix this with the Resin, Wax, and Lard, previously melted together, and keep the whole at the temperature of 212° for fifteen minutes. Lastly, strain the mixture through muslin, and stir it constantly until cool." *U. S.*

This is a new officinal of our Pharmacopœia, adopted from a formula of Mr. Wm. R. Warner, published in the *American Journal of Pharmacy* (Jan. 1860, p. 11), and intended as a substitute for the old *Ceratum Cantharidis*, from which it differs mainly in containing an alcoholic extract of the flies instead of the flies themselves. If the percolation be well conducted, so as to exhaust the cantharides, of which the active matter is soluble in alcohol, this cerate ought theoretically to be more effective than the old blistering cerate; as the active principles are separated from the inert matter of the flies which envelops them in the natural state, and must in some measure interfere with their action; and it is said that its superior efficacy has been practically ascertained. It is to be used in the same manner as the cerate of cantharides. W.

CERATUM PLUMBI SUBACETATIS. *U. S.* UNGUENTUM PLUMBI SUBACETATIS. *Br. Cerate of Subacetate of Lead. Goulard's Cerate.*

"Take of Solution of Subacetate of Lead *two fluidounces and a half;* White Wax *four troyounces;* Olive Oil *eight troyounces;* Camphor *thirty grains.* Mix the Wax, previously melted, with *seven troyounces* of the Oil. Then remove the mixture from the fire, and, when it begins to thicken, gradually pour in the Solution of Subacetate of Lead, stirring constantly with a wooden spatula till it becomes cool. Lastly, add the Camphor, dissolved in the remainder of the Oil, and mix them." *U. S.*

The *British Pharmacopœia* takes *six fluidounces* of the Solution of Subacetate of Lead, *eight ounces* [avoirdupois] of White Wax, *a pint* [Imperial measure] of Olive Oil, and *sixty grains* of Camphor, and proceeds in the man-

ner above directed, except that the wax and oil are melted by means of a steam or water bath, instead of over a fire; and in this respect its directions are more judicious than those of the U. S. Pharmacopœia.

This cerate received the name by which it is commonly known from M. Goulard, by whom it was employed and recommended. It soon begins to assume a yellowish colour, and after a short time becomes so rancid as to be scarcely fit for use. Hence it should be prepared in small quantities at once. The late Mr. Jacob Bell found it more satisfactory when made with yellow wax. (*Pharm. Journ.*, March, 1859, p. 459.) Eggenfels, a German pharmaceutist, recommends the following method of proceeding to prevent its change of colour. The wax and oil are melted in a water-bath; the solution of acetate of lead, previously heated, is added in small portions successively; and the mixture well stirred, and digested for some time; a partial saponification takes place, and an emulsion afterwards; and the cerate retains its white colour. (See *Am. Journ. of Pharm.*, Sept. 1861, p. 408.) It is used chiefly in excoriations, burns, scalds, and chilblains, and in cutaneous eruptions. We have found it more effectual than any other application to blistered surfaces indisposed to heal; and, on the recommendation of the late Dr. Parrish, have used it in the following combination with advantage in various cutaneous eruptions of a local character. Take of cerate of subacetate of lead, simple cerate, each, *half an ounce;* calomel, powdered opium, each, *a drachm;* mix them. The same preparation, without the opium, was a favourite remedy with the late Dr. Wistar in similar complaints. W.

CERATUM RESINÆ. *U. S.* Unguentum Resinæ. *Br. Resin Cerate. Ointment of Resin. Basilicon Ointment.*

"Take of Resin *ten troyounces;* Yellow Wax *four troyounces;* Lard *sixteen troyounces.* Melt them together, strain the mixture through muslin, and stir it constantly until cool." *U. S.*

"Take of Resin, in coarse powder, *eight ounces;* Yellow Wax *four ounces;* Simple Ointment *sixteen ounces.* Melt with a gentle heat, strain the mixture while hot, and stir constantly until it cools." *Br.*

The straining is directed in consequence of the impurities which resin often contains. Resin cerate, commonly called *basilicon ointment*, is much used as a gently stimulant application to blistered surfaces, indolent ulcers, burns, scalds, and chilblains. We have found no application more effectual in disposing the ulcers which follow burns to heal.

Off. Prep. Ceratum Sabinæ, *U. S.;* Linimentum Terebinthinæ, *Br.* W.

CERATUM RESINÆ COMPOSITUM. *U. S. Compound Resin Cerate.*

"Take of Resin, Suet, Yellow Wax, each, *twelve troyounces;* Turpentine *six troyounces;* Flaxseed Oil *seven troyounces.* Mix them together, strain the mixture through muslin, and stir it constantly until cool." *U. S.*

This is somewhat more stimulating than the preceding, but is applicable to similar purposes, particularly to the treatment of indolent ulcers. Under the name of *Deshler's salve*, it is popularly employed in some parts of the United States. It should be kept well protected from the air, in consequence of its liability when exposed to acquire a tough consistence. W.

CERATUM SABINÆ. *U. S.* Unguentum Sabinæ. *Br. Savine Cerate. Ointment of Savine.*

"Take of Savine, in fine powder, *three troyounces;* Resin Cerate *twelve troyounces;* Ether *a sufficient quantity.* Moisten the Savine with Ether, pack it firmly in a cylindrical percolator, and pour on Ether until the filtered liquid passes nearly colourless. Evaporate this spontaneously to the consistence of syrup, add the concentrated liquid to the Resin Cerate, softened by a gentle heat, and mix them thoroughly." *U. S.*

"Take of Fresh Savine, bruised, *eight ounces;* White Wax *three ounces;* Prepared Lard *sixteen ounces.* Melt the Lard and the Wax together on a water-bath, add the Savine, and digest for twenty minutes. Then remove the mixture, and express through calico." *Br.*

As the savine used in this country is generally brought from Europe in the dried state, we are compelled to resort to a mode of preparing the cerate different from that usually employed in Europe. In the Pharmacopœia of 1850, the dried savine was simply mixed, in powder, with resin cerate previously softened; and the proportion used was one part of the powder to six parts of the cerate. Nor did we find the preparation thus made to be "intolerably acrid and almost caustic," as Dr. Duncan described it. On the contrary, it answered very well the purpose for which it was used, that of maintaining the discharge from blistered surfaces. The process, however, of the present edition of the Pharmacopœia is certainly more elegant than the former, and probably, if well executed, will yield a more effective product; as the active matter is extracted by the ether, and must operate more energetically than while entangled in the inert matter of the leaves. The only objection to it is its expensiveness. A cerate, prepared in the same manner as the former cerate, from the leaves of the red cedar (*Juniperus Virginiana*) is sometimes substituted for that of savine, but is less efficient. Prepared according to the process of the *British* Pharmacopœia, savine cerate has a fine deep-green colour, and the odour of the leaves. It should be kept in closely covered vessels.

Savine cerate is preferable to the ointment of Spanish flies as a dressing for perpetual blisters, from the circumstance that it has no tendency to produce strangury. The white coating which forms, during its use, upon the blistered surface should be occasionally removed, as it prevents the contact of the cerate. It is sometimes applied to seton cords, to increase the discharge. W.

CERATUM SAPONIS. *U. S. Soap Cerate.*

"Take of Soap Plaster *two troyounces;* White Wax *two troyounces and a half;* Olive Oil *four troyounces.* Melt together the Plaster and Wax, add the Oil, and, after continuing the heat a short time, stir the mixture until cool." *U. S.*

This is a much neater preparation than that of the Pharmacopœia of 1850, which was made by boiling the solution of subacetate of lead with soap, and then, after concentration, adding the wax and oil melted together; nor is there any reason to suppose that it is less efficient. Soap cerate is thought to be cooling and sedative; and is used in scrofulous swellings and other instances of chronic external inflammation. It was formerly employed by Mr. Pott as a dressing for fractured limbs; but answers no other purpose in these cases than to yield mechanical support. W.

CERATUM ZINCI CARBONATIS. *U.S. Cerate of Carbonate of Zinc.*

"Take of Precipitated Carbonate of Zinc *two troyounces;* Ointment of Lard *ten troyounces.* Mix them." *U. S.*

This preparation is an imitation of the cerate recommended by Turner, and is intended as a substitute for the former Ceratum Zinci Carbonatis and more recent Ceratum Calaminæ of the U. S. Pharmacopœia, as more reliable, in consequence of the frequent falsification of calamine. It is mildly astringent, and is used in excoriations and superficial ulcerations, produced by the chafing of the skin, irritating secretions, burns, or other causes.* W.

* *Ceratum Calaminæ.* U. S. 1850. Though abandoned as an officinal preparation, in consequence of the frequent adulteration or substitution to which calamine is liable, the preparation is still considerably used, and a formula is, therefore, required. The following is the late officinal process. "Take of Prepared Calamine, Yellow Wax, each, *three ounces;* Lard *a pound.* Melt the Lard and Wax together, and when on cooling they begin to thicken, add the Calamine, and stir the mixture constantly until cool." The uses of this cerate are the same as those mentioned in the text, under *Ceratum Zinci Carbonatis.*

CINCHONIA.

Preparation of Cinchonia.

CINCHONIÆ SULPHAS. *U. S. Sulphate of Cinchonia.*

"Take of the mother-water, remaining after the crystallization of Sulphate of Quinia, in the process for preparing that salt, *a convenient quantity;* Solution of Soda, Alcohol, Diluted Sulphuric Acid, Animal Charcoal, in fine powder, each, *a sufficient quantity.* To the mother-water add gradually, with constant stirring, Solution of Soda, until the liquid becomes alkaline. Collect on a filter the precipitate formed, wash it with water, and dry it. Then wash it with successive small portions of Alcohol, to remove other alkaloids which may be present. Mix the residue with eight times its weight of water, and, having heated the mixture, add gradually Diluted Sulphuric Acid until it is saturated and becomes clear. Then boil the liquid with Animal Charcoal, filter it while hot, and set it aside to crystallize. Lastly, drain the crystals, and dry them on bibulous paper. By evaporating the mother-liquid, more crystals may be obtained." *U. S.*

Sulphate of Cinchonia is now for the first time officinally recognised, having been introduced into the U. S. Pharmacopœia at the late revision; and this recognition is certainly justified by its great importance as a medicine. In consequence of its greater solubility it remains behind in the mother-waters, when sulphate of quinia crystallizes, in the process for preparing the latter salt. To separate it from other substances contained in the mother-waters, it is decomposed by solution of soda, which is preferable to potassa, as it forms a very soluble salt with sulphuric acid, whereas the sulphate of potassa, being of difficult solubility, might fall with the precipitated cinchonia. The precipitate may be safely washed with small portions of alcohol, as the alkaloid is almost insoluble in that liquid when cold. It is next reconverted into the sulphate, and, the solution having been boiled with *unpurified* animal charcoal to decolorize it, and at the same time neutralize any possible excess of sulphuric acid which might interfere with the crystallization of the salt, is filtered while hot, and then allowed to stand. It is peculiarly important that there should be no excess of sulphuric acid while the solution is exposed to heat, as, under this influence, the alkaloid is much disposed to become uncrystallizable. Hence the advantage of using unpurified animal charcoal or bone black, as the carbonate of lime contained in it neutralizes any excess of the acid. The sulphate of cinchonia, held in solution by the liquid while hot, is deposited by it upon cooling in crystals.

It may be prepared also by first obtaining cinchonia from one of the pale barks (see *page* 289); treating this with water acidulated with sulphuric acid, added gradually till the alkaloid is dissolved; then boiling with purified animal charcoal, filtering the solution while hot, and setting it aside to crystallize. By alternate evaporation and crystallization all the sulphate may be obtained.

There are two sulphates of cinchonia. The officinal salt may be considered either as the neutral sulphate, consisting of one eq. of cinchonia 308, one of sulphuric acid 40, and two of water of crystallization $18 = 366$; or, according to the view of Liebig, as a *disulphate*, consisting of two eqs. of base 308, one of acid 40, and two of water. By the addition of the necessary quantity of acid, it passes into the higher sulphate (bisulphate, or neutral sulphate, according to the view that may be adopted), which is soluble in less than half its weight of water at 58°. We have always been inclined to the view which considers it as the neutral salt, and this probably now predominates with chemists, so that the salt is properly named sulphate of cinchonia in the Pharmacopœia. It crystallizes in short, oblique, shining prisms with dihedral summits, which melt at 212°, at a somewhat higher temperature lose their water of crystallization, and at a red heat are dissipated, without residue. Its taste is very bitter. It is soluble in

fifty-four parts of water at common temperatures, and in a smaller quantity of boiling water, and is readily dissolved by alcohol, but very sparingly by ether. The tests by which it may be known as a salt of cinchonia are mentioned under the head of *Cinchona* in Part I. (*page* 289). That it is a sulphate will be shown by the white precipitate produced with its solution by chloride of calcium.*

Medical Properties and Uses. It is now pretty well determined that sulphate of cinchonia has the same remedial properties as sulphate of quinia. That it is equally efficient as an antiperiodic remedy, in a somewhat larger dose, has been established by abundant experience. (See a paper, by Dr. A. P. Turner, in the *Am. Journ. of Med. Sci.*, April, 1864, p. 396.) As a tonic it may be given in the dose of a grain or two, three or four times a day; as an antiperiodic, fifteen grains to half a drachm may be given between the paroxysms. It may be taken in pill or solution. In the latter case, the solution of the salt may be aided by the addition of a little aromatic sulphuric acid, in the proportion, for example, of a minim or two drops for each grain of the salt, in a solution of eight grains to a fluidounce of water. W

COLLODIUM.

Preparations of Collodion.

COLLODIUM. *U. S.*, *Br. Collodion.*

"Take of Cotton, freed from impurities, *half a troyounce;* Nitrate of Potassa, in fine powder, *ten troyounces;* Sulphuric Acid *fifteen troyounces and a half;* Stronger Ether *twenty-one fluidounces;* Stronger Alcohol *a sufficient quantity.* Add the Sulphuric Acid to the Nitrate of Potassa in a glass or porcelain vessel, and stir them together until they are uniformly mixed. When the temperature of the mixture is below 122°, add the Cotton, and, by means of stout glass rods, imbue it thoroughly with the mixture. Then cover the vessel closely with a glass or porcelain lid, and allow it to stand for twenty-four hours. Transfer the Cotton to a larger vessel, and wash it, first with cold water until the washings cease to have an acid taste, and then with boiling water. Press it as dry as possible with the hand, pack it tightly in a conical percolator, and pour upon it Stronger Alcohol until the remaining water is displaced; then again press it as dry as possible with the hand. Mix the Stronger Ether with six fluidounces of Stronger Alcohol in a suitable bottle, and, having added the moist Cotton to the mixture, agitate occasionally until it is dissolved. The Cotton, prepared for solution by this formula, and dried at 212°, weighs three hundred and thirty-six grains.

"Collodion may also be made by dissolving fifty-six grains of Cotton, prepared as above, and dried at 212°, in a mixture of three fluidounces and a half of Stronger Ether and a fluidounce of Stronger Alcohol." *U. S.*

"Take of Pyroxylin *one ounce* [avoirdupois]; Ether *thirty-six fluidounces* [Imperial measure]; Rectified Spirit *twelve fluidounces* [Imp. meas.]. Mix the Ether and the Spirit, and add the Pyroxylin. Set aside for a few days, and, should there be any sediment, decant the clear solution. Keep it in a stoppered bottle." *Br.*

Collodion is a solution of freshly prepared gun cotton in ether, assisted by a little alcohol. Gun cotton was originally obtained from cotton by steeping it in nitric acid, by the action of which it is converted into an explosive compound.

* A new test, distinguishing between sulphates of quinia and cinchonia, has recently been announced by M. Palm, of Russia, in the polysulphuret of potassium prepared by boiling solution of potassa with an excess of sulphur. When a solution of this sulphuret is added to a boiling solution of sulphate of quinia, the latter, however small the quantity present, is thrown down as a red terebinthinate mass, which hardens on cooling, and then assumes the appearance of a resin; while with sulphate of cinchonia a white powder is precipitated containing sulphur. (*Journ. de Pharm.*, Mai, 1864, p. 459.)

(See *Gun Cotton* in Part III.) When gun cotton is intended for solution in ether, a better preparation for this purpose is made by the process of Dr. Ellet, of South Carolina College, which consists in steeping cotton in a mixture of nitre and sulphuric acid. This mixture sets free the necessary nitric acid for effecting the change in the cotton. Gun cotton, thus prepared, more readily dissolves in ether than that made by direct reaction of nitric acid; and, for that reason, the process of Dr. Ellet was adopted in the U. S. formula. The present officinal preparation is somewhat stronger than that of the Pharmacopœia of 1850, having a considerably smaller proportion of the ether and alcohol conjointly, though the proportion of alcohol is much increased. On account of the facility with which ether evaporates, it is the better menstruum for remedial purposes; but gun cotton will not dissolve in that liquid when quite pure, and the addition of a little alcohol is necessary. The existing proportion was adjusted by Dr. Squibb, who found by frequent trial some increase in the quantity of alcohol desirable; and the resulting preparation has been found to answer well in practice. The increase of alcohol, however, though the quantity directed is six times greater than before, is in reality much less than this; for the common ether directed in the formula of 1850 itself contains a very considerable proportion of alcohol, while the stronger ether now used has comparatively little. Other improvements in the process are the fixing of the temperature at which the cotton is to be introduced into the acid mixture, which was before left indefinite, and the more complete removal of water from the gun cotton by displacing it with alcohol after expression. The process is now said to work well in practice, and yields a preparation more firm and adhesive than the old formula. Gun cotton, prepared as above directed, is not liable to decomposition, but continues fit for solution in ether for a considerable time. Hence the propriety of the alternative formula, in which the gun cotton, dried at 212°, may be dissolved in a due proportion of the two menstrua. In following the U. S. process, it is necessary that the sulphuric acid be of the officinal strength.

In the British process, gun cotton, denominated pyroxylin, is directed to be dissolved in a mixture of ether and alcohol; a formula for the preparation of pyroxylin being given in the *Appendix* to the Pharmacopœia. It is asserted, however, that the pyroxylin made by that formula, though an excellent explosive compound, is not readily dissolved by the mixture of ether and alcohol. (*Pharm. Journ.*, March, 1864, p. 416.)

Collodion is a transparent, colourless liquid, of a syrupy consistence, and ethereal smell. When applied to a dry surface, the ether quickly evaporates, and a transparent film is left, having remarkable adhesiveness and contractility. On account of the great volatility of ether, collodion must be kept in bottles well stopped. When insecurely kept, the liquid thickens and becomes less fit for the use of the surgeon. The thickened liquid sometimes contains acicular crystals, as was first observed by Mr. Higginson, of London, and afterwards by Prof. Leidy, of this city, who examined it with the microscope.

Collodion was first applied to the purposes of surgery by Mr. J. Parker Maynard, student of medicine, of Boston, in January, 1847. It is employed for holding together the edges of incised wounds, for covering ulcers or abraded surfaces with an impervious film not acted upon by water, and for encasing parts which require to be kept without relative motion. It is applied, brushed over the part, or by means of strips of muslin. In whatever way applied, the solvent quickly evaporates, and leaves the solid adhesive material. According to Lepage, gun cotton will dissolve in equal parts of ether and alcohol, forming a solution quite as adhesive as that made with ether alone. As this solution dries more slowly, it may prove preferable to the ethereal solution in certain cases. The strong contractile power of the collodion coating is an objection to it for some purposes. This property is removed, according to Mr. C. S. Raud, of Philadelphia, by dis-

solving first one part of gun cotton, and then one part of Venice turpentine, in twenty parts of ether. To give more flexibility to the film, M. Sourisseau, of Kaiserberg, adds one part of elemi to twelve of collodion. According to Mr. Startin, of London, opacity and elasticity may be imparted at the same time, by adding from half a drachm to a drachm of lard, or some similar fatty matter, previously dissolved in ether, to an ounce of collodion. The qualities of softness and elasticity are given by combining collodion with castor oil, in the proportion of thirty parts to two, agreeably to the plan of M. Guérsant, who found it useful, thus modified, in erysipelas; and the proportion of castor oil may be increased if thought desirable. An elastic collodion, somewhat similar, in which, besides castor oil, Venice turpentine and white wax are ingredients, has been proposed by E. Lauras. (*Pharm. Journ.*, xii. 303.) A very pliable collodion may be made of thirty parts of collodion, twelve of Venice turpentine, and six of castor oil. According to MM. Cap and Garot, the most successful way for obtaining an elastic collodion is to mix two parts of glycerin with one hundred of collodion. *Glycerized collodion* is exceedingly supple, does not crack and scale off from the skin, and accommodates itself to the motions of the part. In order to imitate the colour of the skin, an ethereal tincture of turmeric or saffron may be added, so as to produce the desired tint. Dr. Meller has proposed a solution of shell-lac in highly rectified alcohol, so as to have a gelatinous consistence, as a succedaneum for collodion.

Collodion has been used with advantage by Dr. J. R. Mitchell, of Dublin, and by Dr. Aran, to form an artificial covering to ulcers of the os and cervix uteri, thereby allowing the healing process to go on underneath; by M. Weizlar, of Aix-la-Chapelle, in chilblains; and by Dr. J. W. Freer, of Illinois, in erysipelas. According to Dr. Christen, of Prague, collodion is useful in erysipelas from local causes only, such as wounds, ulcers, burns, &c., but hurtful in the disease from an internal cause. The same writer condemns its use to prevent pitting in small-pox as positively injurious. In burns collodion has been found highly useful by several practitioners, especially in conjunction with castor oil. Its application produces sharp pain at first. It acts by affording a protective covering to the cutis, and, in superficial inflammation, probably, in part, by expelling the blood from the inflamed vessels through the contractile power of the film. This property of collodion has been taken advantage of in the treatment of chronic entropium, two cases of which, successfully treated by it, have been reported by Mr. William Batten. (*Ranking's Abstract*, No. 23, p. 134.) Dr. J. H. Claiborne has used a thick coating of collodion with decided advantage as a compressing agent for the discussion of buboes. It is said to have proved useful in phlegmasia dolens, and is asserted even to have cured a case of puerperal peritonitis, spread over the surface of the abdomen. (*Med. Times and Gaz.*, Oct. 1859, p. 342.)

Mr. Erasmus Wilson has used collodion with decided advantage in certain diseases of the skin. In chapped nipples it has an admirable effect. When applied to ulcers, abrasions, or chaps of the skin, it requires to be diluted with ether, so as to render it nearly as limpid as water. Mr. J. H. Tucker found it useful in stopping the bleeding from leech-bites. M. Sourisseau and Mr. E. H. Durden have used it as a coating for pills, which are thereby deprived of taste, but not injured in medical properties.

Collodion has been variously medicated, and thus made the vehicle of several important medicines for external application. *Iodized collodion* has been proposed by Dr. C. Fleming, for the purpose of obtaining the specific effects of iodine in a rapid manner, especially on tumours. It is made by dissolving from ten to twenty grains of iodine in a fluidounce of collodion. M. Aran has proposed a *ferruginous collodion*, made of equal parts of collodion and tincture of chloride of iron, as a remedy in erysipelas. A *caustic collodion* may be prepared by dissolving 4 parts of corrosive sublimate in 30 of collodion. Dr. Macke, of Soran,

has used this preparation for destroying nævi materni. The eschar formed is one or two lines in thickness, and separates in from three to six days, leaving but a trifling cicatrix. (See *Am. Journ. of Pharm.*, May, 1858, for formulas in which collodion is made the vehicle of iodine, belladonna, sulphur, &c.) All these medicated collodions are most conveniently applied by means of a camel's hair brush.

Collodion has become an important agent in various photographic processes.

B.

COLLODIUM CUM CANTHARIDE. *U. S. Collodion with Cantharides. Cantharidal Collodion.*

"Take of Cantharides, in fine powder, *eight troyounces;* Cotton, prepared by the process for Collodion, and dry, *one hundred grains;* Stronger Ether *a pint and a half;* Stronger Alcohol *a sufficient quantity.* Introduce the Cantharides into a cylindrical percolator, and, having pressed them firmly, gradually pour on the Ether. When fifteen fluidounces have passed, set aside the liquid in a close vessel, and continue the percolation with Stronger Alcohol until half a pint more of liquid is obtained. Set this in a warm place for spontaneous evaporation, and, when it is reduced to a fluidounce, mix it with the reserved liquid. Then add the Cotton to the mixture, and agitate occasionally until it is dissolved. Lastly, keep the solution in a well-stopped bottle." *U. S.*

This was originally proposed by M. Ilisch, of St. Petersburg, Russia, and was introduced into our Pharmacopœia at the late revision. The flies are exhausted successively by ether and alcohol, the ethereal solution is set aside, the alcoholic is allowed to evaporate till reduced from eight fluidounces to one, and the two liquids being then mixed are used as the menstruum for gun cotton. But, considering the character of the menstruum, it appears to us that it must frequently fail to dissolve the cotton; as a larger proportion of alcohol is required for the purpose than will remain when the tincture has been reduced to one fluidounce by evaporation. Had common ether, which always contains a considerable proportion of alcohol, been adopted instead of stronger ether, there would probably have been enough alcohol to render the process effectual, and economy would at the same time have been consulted. Should, therefore, the formula fail in the hands of the operator, we would suggest the substitution of the common ether. The original process of M. Ilisch was to exhaust, by percolation, a pound of cantharides, with a mixture consisting of a pound of ether and three ounces of acetic ether; and in two ounces of this liquid dissolve 25 grains of gun cotton. Professor Procter states that it has been found more advantageous to exhaust the flies with ether, distil off the ether, and mix the oily residue with collodion already prepared of the proper consistence (*Am. Journ. of Pharm.*, xxiv. 303); and this is probably a better formula than the officinal. Mr. Charles S. Rand, in a communication to the *American Journal of Pharmacy* (xxii. 18), states that Ilisch's preparation, made with double the proportion of ether, vesicates equally well, and proposes the addition of about 1 per cent. of Venice turpentine, which he has found to prevent the disagreeable and sometimes painful contraction of the preparation upon drying. The preparation may be kept indefinitely, in an opaque glass-stoppered bottle, without change; but, on exposure to the light, the greenish colouring matter of the flies bleaches, and the liquid becomes yellowish.

Cantharidal collodion is a very convenient epispastic remedy. It may be applied to the surface by means of a camel's hair brush, and, after the evaporation of the ether, which takes place in less than a minute, may be reapplied if the surface should not be well covered. It produces a blister in about the same time as the ordinary cerate, and has the advantages that it is applied with greater facility, is better adapted to cover uneven surfaces, and retains its place more certainly. According to Mr. Rand, if the evaporation of the ether be restrained by a piece of oiled silk immediately after its application, it will act much more speedily.

W.

CONFECTIONES. *U. S., Br.*

Confections.

Under the general title of Confections, the Pharmacopœias include all those preparations having the form of a soft solid, in which one or more medicinal substances are incorporated with saccharine matter, with a view either to their preservation or more convenient administration. The old division into Conserves and Electuaries has been abandoned; but, as there is some ground for the distinction, we shall make a few general remarks upon each division, before proceeding to the consideration of the individual preparations.

Conserves consist of recent vegetable substances and refined sugar beat into a uniform mass. By means of the sugar, the vegetable matter is enabled to resist for some time the decomposition to which it would otherwise be exposed in the undried state, and the properties of the recent plant are thus retained to a certain extent unaltered. But, as active medicines even thus treated undergo some change, and those which lose their virtues by desiccation cannot be long preserved, the few conserves now retained are intended rather as convenient vehicles of other substances than for separate exhibition. The sugar used in their preparation should be reduced to a fine powder by pounding and sifting, as otherwise it will not mix uniformly with the other ingredients.

Electuaries are mixtures consisting of medicinal substances, especially dry powders, combined with syrup or honey, in order to render them less unpleasant to the taste, and more convenient for internal use. They are usually prepared extemporaneously; and it is only when their complex nature renders it convenient to keep them ready made in the shops, or some peculiarity in the mode of mixing the ingredients requires attention, that they become proper objects for officinal direction. Their consistence should not be so soft, on the one hand, as to allow the ingredients to separate, nor so firm, on the other, as to prevent them from being swallowed without mastication. Different substances require different proportions of syrup. Light vegetable powders usually require twice their weight, gum-resins two-thirds of their weight, resins somewhat less, mineral substances about half their weight, and deliquescent salts not more than one-tenth. Should the electuary be found, after having been kept for a short time, to swell up and emit gas, it should be beat over again in a mortar, so that any portion of the sugar which may have crystallized may be again accurately incorporated with the other ingredients. Should it, on the contrary, become dry and hard from the mutual reaction of its constituents, more syrup should be added, so as to give it the requisite consistence. If the dryness result from the mere evaporation of the aqueous part, water should be added instead of syrup, and the same remark is applicable to the conserves. To prevent the hardening of electuaries, the French writers recommend the use of syrup prepared from brown sugar, which is less apt to crystallize than that made from the refined. Molasses would answer the same purpose; but its taste might be objectionable. Some employ honey, but this is not always acceptable to the stomach. W.

CONFECTIO AROMATICA. *U. S. Aromatic Confection.*

"Take of Aromatic Powder *four troyounces;* Clarified Honey *four troyounces*, or *a sufficient quantity*. Rub the Aromatic Powder with Clarified Honey until a uniform mass is obtained of the proper consistence." *U. S.*

The aromatic confection has been abandoned in the Br. Pharmacopœia, probably because readily prepared extemporaneously. It affords, nevertheless, a convenient means of administering the spices contained in it, and an agreeable vehicle for other medicines. The present U. S. formula differs favourably from that of 1850 in the omission of the saffron; and the place of the syrup of orange peel has been economically supplied by using a larger proportion of honey

The confection is given in debilitated states of the stomach. The dose is from ten to sixty grains. W

CONFECTIO AURANTII CORTICIS. *U. S.* *Confection of Orange Peel.*

"Take of Sweet Orange Peel, recently separated from the fruit by grating, *twelve troyounces;* Sugar [refined] *thirty-six troyounces.* Beat the Orange Peel with the Sugar, gradually added, until they are thoroughly mixed." *U. S.*

This confection, like the preceding, has been dropped in the recent consolidation of the British Pharmacopœias. It is sometimes used as a grateful aromatic vehicle or adjunct of tonic and purgative powders. W.

CONFECTIO OPII. *U. S.* *Confection of Opium.*

"Take of Opium, in fine powder, *two hundred and seventy grains;* Aromatic Powder *six troyounces;* Clarified Honey *fourteen troyounces.* Rub the Opium with the Aromatic Powder, then add the Honey, and beat the whole together until thoroughly mixed." *U. S.*

This confection was intended as a substitute for those exceedingly complex and unscientific preparations, formerly known by the names of *theriaca* and *mithridate*, which have been expelled from modern pharmacy. It was an officinal of the London and Edinburgh Colleges; but has been discarded in the British Pharmacopœia. The preparation is a combination of opium with spices, which render it more stimulant, and more grateful to a debilitated stomach. It may be given in atonic gout, flatulent colic, diarrhœa unattended with inflammation, and other diseases requiring the use of a stimulant narcotic. Added to Peruvian bark or sulphate of quinia, it increases the efficacy of this remedy in obstinate cases of intermittent fever. One grain of opium is contained in about thirty-six grains of the confection. W.

CONFECTIO PIPERIS. *Br.* *Confection of Black Pepper.*

"Take of Black Pepper, in fine powder, *two ounces;* Caraway, in fine powder, *three ounces;* Clarified Honey *fifteen ounces.* Rub them well together in a mortar." *Br.*

This preparation was intended as a substitute for *Ward's paste*, which acquired some reputation in Great Britain as a remedy in piles and ulcers of the rectum. To do good, it must be continued, according to Mr. Brodie, for two, three, or four months. The dose is from one to two drachms repeated two or three times a day. Its stimulating properties render it inapplicable to cases attended with much inflammation. W.

CONFECTIO ROSÆ. *U. S.* CONFECTIO ROSÆ GALLICÆ. *Br.* *Confection of Rose. Confection of Roses.*

"Take of Red Rose, in fine powder, *four troyounces;* Sugar [refined], in fine powder, *thirty troyounces;* Clarified Honey *six troyounces;* Rose Water *eight fluidounces.* Rub the Rose with the Rose Water heated to 150°; then gradually add the Sugar and Honey, and beat the whole together until thoroughly mixed." *U. S.*

"Take of Fresh Red-Rose Petals *one pound;* Refined Sugar *three pounds.* Beat the Petals to a pulp in a stone mortar; add the Sugar, and rub them well together." *Br.*

In the British process the unblown petals only are used, and these should be deprived of their claws; in other words, the rose buds should be cut off a short distance above their base, and the lower portion rejected. In the last three editions of the U. S. Pharmacopœia, dried roses have been substituted for the fresh, as the latter are not brought to our market. The process is very similar to that of the French Codex. We have been informed, however, that much of the confection of roses made in Philadelphia is prepared from the fresh petals of the

hundred-leaved rose and others, by beating them into a pulp with sugar, as in the British process. An excuse for this deviation from the officinal formula is, that the confection thus made has greater adhesiveness than the officinal, and is therefore better fitted for the formation of pills.

This confection is slightly astringent, but is almost exclusively used as a vehicle of other medicines, or to impart consistence to the pilular mass.

Off. Prep. Pilula Aloës Barbadensis, *Br.;* Pil. Aloës et Assafœtidæ, *Br.;* Pil. Aloës et Myrrhæ, *Br.;* Pil. Aloës Socotrinæ, *Br.;* Pil. Ferri Carbonatis, *Br.;* Pilulæ Hydrargyri; Pil. Plumbi cum Opio, *Br.* W.

CONFECTIO ROSÆ CANINÆ. *Br. Confection of Hips.*

"Take of Hips, carefully deprived of their seeds, *one pound;* Refined Sugar, *two pounds.* Beat the Hips to a pulp in a stone mortar, add the Sugar, and rub them well together." *Br.*

This preparation is acidulous and refrigerant, and is used in Europe for forming more active medicines into pills and electuaries. W.

CONFECTIO SCAMMONII. *Br. Confection of Scammony.*

"Take of Scammony, or Resin of Scammony, in fine powder, *three ounces;* Ginger, in fine powder, *one ounce and a half;* Oil of Caraway *one fluidrachm;* Oil of Cloves *half a fluidrachm;* Syrup *three fluidounces;* Clarified Honey *one ounce and a half.* Rub the powders with the Syrup and the Honey into a uniform mass, then add the Oils and mix." *Br.* The ounce used in this process is the avoirdupois ounce.

The confection is actively cathartic in the dose of half a drachm or a drachm; but is very little used. It would seem that, according to the British Pharmacopœia, it was a matter of indifference whether scammony or its resin should be used. As this drug is generally found in the market, it has but little more than half the strength of the resin. It is true that the purest and best scammony is much stronger than this, yet it is decidedly weaker than its resin, and the Pharmacopœia itself describes it as containing only from 80 to 90 per cent. of this ingredient. It appears to be a strange want of precision thus to confound the two, as if they were to be given in the same dose. W.

CONFECTIO SENNÆ. *U.S., Br. Confection of Senna. Lenitive Electuary.*

"Take of Senna, in fine powder, *eight troyounces;* Coriander, in fine powder, *four troyounces;* Purging Cassia, finely bruised, *sixteen troyounces;* Tamarind *ten troyounces;* Prune, sliced, *seven troyounces;* Fig, bruised, *twelve troyounces;* Sugar, in coarse powder, *thirty troyounces;* Water *a sufficient quantity.* Digest, in a close vessel, by means of a water-bath, the Purging Cassia, Tamarind, Prune, and Fig in three pints of Water for three hours. Separate the coarser portions with the hand, and pass the pulpy mass, by rubbing, first through a coarse hair sieve, and then through a fine one, or a muslin cloth. Mix the residue with a pint of Water, and, having digested the mixture for a short time, treat it as before, and add the product to the pulpy liquid first obtained. Then, by means of a water-bath, dissolve the Sugar in the pulpy liquid, and evaporate the whole until it weighs ninety-six troyounces, or until it has been brought to the consistence of honey. Lastly, add the Senna and Coriander, and incorporate them thoroughly with the other ingredients while yet warm." *U.S.*

"Take of Senna, in fine powder, *seven ounces;* Coriander, in fine powder, *three ounces;* Figs *twelve ounces;* Tamarinds *nine ounces;* Cassia Pulp *nine ounces;* Prunes *six ounces;* Extract of Liquorice, *three-quarters of an ounce;* Refined Sugar *thirty ounces;* Distilled Water *twenty-four fluidounces.* Boil the Figs gently in the Water in a covered vessel for four hours; then express and strain the liquor; and, having added more Distilled Water to make up the

quantity to twenty-four fluidounces, put into it the Prunes, and boil as before for four hours. Add the Tamarinds and the Cassia; macerate for a short time; and press the pulp through a hair sieve. Dissolve the Sugar and the Extract of Liquorice in the mixture with a gentle heat; and, while it is still warm, add to it gradually the mixed Senna and Coriander, and stir diligently until all the ingredients are thoroughly combined. The resulting Confection should weigh sixty ounces." *Br.* The ounce employed in the British process is the avoirdupois ounce.

The confection of senna, when properly made, is an elegant preparation, and keeps well if properly secured. The present U. S. process differs from the old in preparing the pulps, as suggested in former editions of this Dispensatory, instead of taking them already prepared; and this is no doubt the best plan. The only material difference is the omission of the liquorice root in the present formula, and this is of no other consequence than that its taste may be missed in the confection. It is not uncommon to omit the cassia pulp in the preparation of the confection, as the pods are not always to be found in the market. But, as this is next to senna the most active ingredient, the omission is to be regretted; and there is no doubt that a steady demand for the fruit would be met by an abundant supply from the West Indies.*

This is one of our best and most pleasant laxatives, being admirably adapted to cases of habitual costiveness, especially in pregnant women and persons affected with piles. It is also very useful in the constipation which is apt to attend convalescence from fevers and other acute diseases. The mean dose is two drachms, to be taken at bedtime. W.

CONFECTIO SULPHURIS. *Br. Confection of Sulphur.*

"Take of Sublimed Sulphur *four ounces* [avoirdupois]; Acid Tartrate of Potassa *one ounce* [avoird.]; Syrup of Orange Peel *four fluidounces.* Rub them well together." *Br.*

This is merely a mode of administering the two laxatives sulphur and bitartrate of potassa; and the relative proportion of the latter is so small that it can have little effect. The dose is from two to four drachms or more. W.

CONFECTIO TEREBINTHINÆ. *Br. Confection of Turpentine.*

"Take of Oil of Turpentine *one fluidounce;* Liquorice Root, in powder, *one ounce* [avoirdupois]; Clarified Honey *two ounces* [avoird.]. Rub the Oil of Turpentine with the Liquorice, add the Honey, and mix them together to a uniform consistence." *Br.*

Confections might be multiplied indefinitely upon the principle which appears to have been adopted here, that, namely, of giving a convenient formula for the administration of medicines. The effects of this confection are those only of the oil of turpentine. The dose may be from a scruple to a drachm. W.

CUPRUM.

Preparation of Copper.

CUPRUM AMMONIATUM. *U. S. Ammoniated Copper.*

"Take of Sulphate of Copper *half a troyounce;* Carbonate of Ammonia *three hundred and sixty grains.* Rub them together in a glass mortar until efferves-

* Senna has been variously prepared to obtain the effects of this confection, in a more agreeable, or less complex form. Thus, under the name of *medicated prunes* a confection is prepared by mixing prunes with concentrated infusion of senna, and evaporating with a gentle heat to the proper consistence, a little sugar being added to improve the flavour; *senna figs* appear to be made by slitting figs, and impregnating the interior parts with extract or powder of senna; and *senna paste* consists of figs and powdered senna, beaten thoroughly together to the consistence of a confection, and then covered with granulated sugar. —*Note to the eleventh edition.*

cence ceases. Then wrap the Ammoniated Copper in bibulous paper, dry it with a gentle heat, and keep it in a well-stopped glass bottle." *U. S.*

When the two salts above mentioned are rubbed together, a reaction takes place between them, attended with the extrication of the water of crystallization of the sulphate of copper, which renders the mass moist, and with the simultaneous escape of carbonic acid gas from the carbonate (sesquicarbonate) of ammonia, which occasions an effervescence. The colour is at the same time altered, passing from the light blue of the powdered sulphate of copper to a beautiful deep azure. The nature of the chemical changes which take place is not precisely known. One of the views which have been taken is, that the blue vitriol parts with a portion of its acid to the ammonia of the carbonate, thus forming a subsulphate of copper and sulphate of ammonia, which are either mixed together, or chemically united in the form of a double salt, the sulphate of copper and ammonia. According to Phillips, the sulphuric acid of the sulphate of copper unites with the ammonia of a portion of the sesquicarbonate of ammonia; while the carbonic acid of the decomposed sesquicarbonate partly escapes, and partly combines with the oxide of copper; so that the resulting preparation consists of sulphate of ammonia, carbonate of copper, and undecomposed sesquicarbonate of ammonia. It is highly probable that Cuprum Ammoniatum, independently of the excess of sesquicarbonate of ammonia which it may contain, is identical with the crystallized salt obtained by dropping a solution of pure ammonia into a solution of sulphate of copper till the subsalt first thrown down is dissolved, then concentrating, and precipitating by alcohol. Now, from the analysis of this salt by Berzelius, it appears to contain one equivalent of sulphuric acid, one of oxide of copper, two of ammonia, and one of water, which may be supposed to be combined in the form of a double salt—the *cupro-sulphate of ammonia*—consisting of one eq. of sulphate of ammonia, one of cuprate of ammonia, in which the oxide of copper acts the part of an acid, and one of water of crystallization ($NH_3.SO_3+NH_3.CuO+HO$). But as half an ounce of sulphate of copper would require for such a result somewhat less than the same weight of sesquicarbonate of ammonia, there must be a considerable excess of the latter salt, unless dissipated in the drying process. In the uncertainty which exists as to the precise nature of the preparation, the name of *ammoniated copper* appears to be the most appropriate as a pharmaceutical title.

This salt has a beautiful deep azure-blue colour, a strong ammoniacal odour, and a styptic, metallic taste. It is soluble in water, and the solution has an alkaline reaction on vegetable colours; but, unless there be excess of sesquicarbonate of ammonia, the solution deposits subsulphate of copper if much diluted. When exposed to the air it parts with ammonia, and is said to be ultimately converted into sulphate of ammonia and carbonate of copper. This change is apt to occur, to a greater or less extent, while it is drying. It should not, therefore, be prepared in large quantities at a time, and should be kept in well-closed bottles. By heat the whole of it is dissipated, except the oxide of copper. Arsenious acid precipitates a green arsenite of copper from its solution. Potassa, soda, lime-water, and the acids are incompatible with it.

Medical Properties and Uses. Ammoniated copper is tonic, and is thought to exercise an influence over the nervous system which renders it antispasmodic. It has been much employed in epilepsy, in which it was recommended by Cullen. There is good reason to believe that it has occasionally effected cures; but like all other remedies in that complaint it very frequently fails. It has also been used in chorea, hysteria, and worms; and by Swediaur as an injection in gonorrhœa and leucorrhœa. In overdoses it produces vomiting, and the poisonous effects which result from the other preparations of copper. (See *Cuprum.*) It is said, however, to be less apt to excite nausea. The dose is a quarter or half a grain, repeated twice a day, and gradually increased to four or five grains. It

may be given in pill or solution. The medicine should not be very long continued without interruption; according to Cullen, not longer than a month. It has been discarded by the British Council; but surely it must be still used in Great Britain to an extent, which would render expedient an officinal regulation of the mode of preparing it. W.

DECOCTA.

Decoctions.

Decoctions are solutions of vegetable principles, obtained by boiling the substances containing these principles in water. Vegetables generally yield their soluble ingredients more readily, and in larger proportion, to water maintained at the point of ebullition, than to the same liquid at a lower temperature. Hence decoction is occasionally preferred to infusion as a mode of extracting the virtues of plants, when the call for the remedy is urgent, and the greatest possible activity in the preparation is desirable. The process should be conducted in a covered vessel, so as to confine the vapour over the surface of the liquid, and thus prevent the access of atmospheric air, which sometimes exerts an injurious agency upon the active principle. The boiling, moreover, should not, as a general rule, be long continued; as the ingredients of the vegetable are apt to react on each other, and thus lose, to a greater or less extent, their original character. The substance submitted to decoction should if dry be either powdered or well bruised, if fresh, should be sliced, so that it may present an extensive surface to the action of the solvent; and previous maceration for some time in water is occasionally useful by overcoming the cohesion of the vegetable fibre. Should the physician not happen to prescribe this preliminary comminution, the apothecary should nevertheless not omit it.

All vegetable substances are not proper objects for decoction. In many the active principle is volatile at a boiling heat, in others it undergoes some change unfavourable to its activity, and in a third set is associated with inefficient or nauseous principles, which, though insoluble, or but slightly soluble in cool water, are abundantly extracted by that liquid at the boiling temperature, and thus encumber, if they do not positively injure the preparation. In all these instances, infusion is preferable to decoction. Besides, by the latter process, more matter is often dissolved than the water can retain, so that upon cooling a precipitation takes place, and the liquid is rendered turbid. When the active principle is thus dissolved in excess, the decoction should always be strained while hot; so that the matter which separates on cooling, may be mixed again with the fluid by agitation at the time of administering the remedy.

In compound decoctions, the ingredients may be advantageously added at different periods of the process, according to the length of boiling requisite for extracting their virtues; and, should any one of them owe its activity to a volatile principle, the proper plan is, at the close of the process, to pour upon it the boiling decoction, and allow the liquor to cool in a covered vessel.

As a general rule, glass or earthenware vessels should be preferred; as those made of metal are sometimes corroded by the ingredients of the decoction, which thus becomes contaminated. Vessels of clean cast-iron or common tin, or of block tin, are preferable to those of copper, brass, or zinc; but iron pots should not be used when astringent vegetables are concerned.

Decoctions, from the mutual reaction of their constituents, as well as from the influence of the air, are apt to spoil in a short time. Hence they should be prepared only when wanted for use, and should not be kept, in warm weather, for a longer period than forty-eight hours.

The new directions for decoctions in the U. S. Pharmacopœia meet, as a general rule, all the requisitions above mentioned, and are remarkably neat and pre-

cise. It is, however, to be feared that, in the aim at uniformity, in itself very desirable, the peculiar qualities of the substances submitted to the process, requiring peculiar treatment, have, in some instances, been overlooked. The directions, moreover, are adapted to the wants of the pharmaceutist, and cannot always be conveniently carried out in families, to whom the preparation of this class of medicines must often be confided. In such instances, it might be better for the physician simply to order the drug to be boiled in a covered vessel, for a certain length of time, or down to a certain amount, in a given quantity of water; as directed in former editions of the U. S. Pharmacopœia, and still directed, as a general rule, in that of Great Britain. Our list of officinal decoctions had been on former occasions so well freed from useless formulas that, at the recent revision, there did not seem to be sufficient cause to dismiss a single one from the list; while, in the British Pharmacopœia, not less than 17 of this class, formerly directed by the three Colleges, were discarded. These were the Decoctions of *Pipsissewa*, *Pale* and *Red Cinchona*, *Quince Seed*, *Bittersweet*, *Galls*, *Pomegranate Rind*, *Guaiacum Wood*, *Mezereon*, *Myrrh*, *Seneka*, *Tormentil*, *Elm Bark*, and *Uva Ursi*, and the Compound Decoctions of *Barley*, *Flaxseed*, and *Broom*. W.

DECOCTUM ALOES COMPOSITUM. *Br.* *Compound Decoction of Aloes.*

"Take of Extract of Socotrine Aloes *ninety grains;* Myrrh, bruised, Saffron, chopped fine, each, *sixty grains;* Carbonate of Potash *forty grains;* Extract of Liquorice *half an ounce* [avoirdupois]; Compound Tincture of Cardamom *four fluidounces;* Distilled Water *a sufficiency.* Triturate the Aloes, Myrrh, and Carbonate of Potash together; add the Saffron and Extract of Liquorice, and boil in fourteen [fluid]ounces of the Water for ten minutes in a covered vessel. Cool, strain through flannel, and add the Tincture of Cardamom, with as much water as may be necessary to make up the quantity of sixteen fluidounces." *Br.*

This is essentially the former process of the British Colleges. The direction is properly given to rub the aloes, myrrh, and carbonate of potassa together before the addition of the other ingredients. The effect of the alkaline carbonate is, by combining with the resin of the myrrh, and the insoluble portion (apotheme of *Berzelius*) of the aloes, to render them more soluble in water, while the liquorice assists in the suspension of the portion not actually dissolved. The tincture of cardamom is useful not only by its cordial property, but also by preventing spontaneous decomposition. This decoction is said not to filter clear when first made, but, if kept for some time, to deposit insoluble matter, and then to become bright and clear on filtering. (*Pharm. Journ.*, xiv. 491.)

Long boiling impairs the purgative property of aloes; and the same effect is thought to be produced, to a certain extent, by the alkalies, which certainly qualify its operation, and render it less apt to irritate the rectum. This decoction, therefore, is milder as a cathartic than aloes itself, and not so liable to produce or aggravate hemorrhoidal disease. At the same time it is more tonic and cordial from the presence of the myrrh, saffron, and cardamom, and derives antacid properties from the carbonate of potassa. It is given as a gentle cathartic, tonic, and emmenagogue; and is especially useful in dyspepsia, habitual constipation, and those complicated cases in which suppressed or retained menstruation is connected with enfeebled digestion and a languid state of bowels. The dose is from half a fluidounce to two fluidounces. The decoction should not be combined in prescription with acids, acidulous salts, or other saline bodies which are incompatible with the alkaline carbonate. W.

DECOCTUM CETRARIÆ. *U. S., Br.* *Decoction of Iceland Moss.*

"Take of Iceland Moss *half a troyounce;* Water *a sufficient quantity.* Boil the Iceland Moss in a pint of Water for fifteen minutes, strain with compression.

and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

"Take of Iceland Moss *one ounce* [avoirdupois]. Distilled Water *one pint and a half*. Wash the Moss in cold water, to remove impurities; boil it with the Distilled Water for ten minutes in a covered vessel, and strain while hot. The product should measure about a pint." *Br.*

The directions of the U. S. Pharmacopœia of 1850 were to boil *half an ounce* of the Moss with *a pint and a half* of Water down to a pint, and to strain with compression; and this process is preferable when the object is to extract not only the bitter principle, but also the whole of the demulcent and nutritive matter. As the bitter principle is dissolved along with the starch-like matter of the moss, this decoction unites an unpleasant flavour to its demulcent properties; but the plan which has been proposed of first extracting the bitterness by maceration in water, or a very weak solution of an alkaline carbonate, and afterwards preparing the decoction, is inadmissible; as the peculiar virtues which distinguish the medicine from the ordinary demulcents are thus entirely lost. (See *Cetraria.*) A pint of the decoction may be taken during the day. W.

DECOCTUM CHIMAPHILÆ. *U. S.* *Decoction of Pipsissewa. Decoction of Winter Green.*

"Take of Pipsissewa, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Pipsissewa in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

Though, in our estimation, a very valuable medicine, this decoction does not appear to be much used abroad, and has been omitted in the British Pharmacopœia. The U. S. directions of 1850 were to boil an ounce of the bruised leaves with a pint and a half of water to a pint, and strain; and, having been much in the habit of using the decoction thus prepared, and found it to answer our purposes well, we must confess a wish that the same direction in reference to the amount of boiling had been retained.

The medical properties and uses of pipsissewa have been detailed under the head of Chimaphila. One pint of the decoction may be given in the course of twenty-four hours. W.

DECOCTUM CINCHONÆ FLAVÆ. *U. S., Br.* *Decoction of Yellow Cinchona. Decoction of Yellow Bark.*

"Take of Yellow Cinchona, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Yellow Cinchona in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

"Take of Yellow Cinchona Bark, in coarse powder, *one ounce* [avoirdupois]; Distilled Water *one pint* [Imp. meas.]. Boil for ten minutes in a covered vessel. Strain the decoction, when cold, through calico; and add sufficient Distilled Water through the filter to make up the quantity to sixteen fluidounces." *Br.* W.

DECOCTUM CINCHONÆ RUBRÆ. *U. S.* *Decoction of Red Cinchona. Decoction of Red Bark.*

"Take of Red Cinchona, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Red Cinchona in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

The British Council has discarded this decoction, and there is no necessity for making distinct formulas for the several varieties. It would, we think, be better to have but one formula for all the varieties, with the general name of Decoctum Cinchonæ, and to leave to the physician the special designation.

The virtues of Peruvian bark, though extracted more rapidly by decoction

than by infusion, are materially impaired by long boiling, in consequence of the changes effected in its constituents, either by their mutual reaction, or by the agency of atmospheric oxygen, or by both causes united. To prevent this result, the process should be performed in a covered vessel, and continued only ten or at the furthest fifteen minutes. But, even with these precautions, a considerable precipitate takes place in the decoction upon cooling, which is thus rendered turbid. According to Pelletier, besides the kinates of cinchonia and quinia, the water dissolves gum, starch, yellow colouring matter, kinate of lime, tannin, and a portion of cinchonic red, with a minute quantity of fatty matter. But the tannin and starch, at the boiling temperature, unite to form a compound insoluble in cold water; and, when the decoction is allowed to cool, this compound is precipitated, together with a portion of the cinchonic red and fatty matter, which carry with them also a considerable quantity of the alkaline principles of the bark. (*Journ. de Pharm.*, vii. 119.) Hence, the decoction is ordered to be strained while hot, so that the portion of active matter precipitated may be mingled by agitation with the liquor, and not be lost. Pelletier recommends that a larger proportion of water, sufficient to retain the alkaloid in solution, be employed, that the decoction be filtered when cold, and then sufficiently concentrated by evaporation. A better mode is to add to the liquid some acid which may form with the quinia and cinchonia compounds more soluble than the native salts. Lemon juice has been long employed as a useful addition to the decoction of cinchona, and we can now understand the manner in which it acts. Sulphuric acid in excess answers the same purpose. By acidulating the pint of water employed in preparing the decoction with a fluidrachm of the aromatic or diluted sulphuric acid, we shall probably enable the menstruum to extract all the virtues of the bark. The propriety of such an addition is confirmed by the experiments of *MM. Henry, jun.*, and *Plisson*, who have ascertained that portions of the alkaloids exist in the bark connected with the colouring matter in the form of insoluble compounds, and that it is impossible, therefore, completely to exhaust the bark by water alone. There may, however, be some diversity of action in the different salts of quinia and cinchonia; and the native kinates may, under certain circumstances, be most efficient.

Numerous substances produce precipitates with this decoction; but comparatively few affect its activity as a medicine. (See *Infusum Cinchonæ.*) Tannic acid and the substances containing it should be excluded from the decoction; as it forms salts with the alkaline principles of the bark, which are either insoluble or but slightly soluble in water. The alkalies, alkaline earths, and salifiable bases generally should also be excluded; because, uniting with the kinic acid, they precipitate the alkaloids.

The dose of the decoction is two fluidounces, to be repeated more or less frequently according to circumstances. Two drachms of orange peel, added to the decoction while still boiling hot, improve its flavour, and render it more acceptable to the stomach. W.

DECOCTUM CORNÛS FLORIDÆ. *U. S.* *Decoction of Dogwood.*

"Take of Dogwood, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Dogwood in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

This decoction has been proposed as a substitute for that of Peruvian bark; but, though possessed of analogous properties, it is much inferior in efficacy, and is not likely to be extensively employed so long as the Peruvian tonic is attainable. The dose is two fluidounces. W.

DECOCTUM DULCAMARÆ. *U. S.* *Decoction of Bittersweet.*

"Take of Bittersweet, bruised, *a troyounce;* Water *a sufficient quantity.*

Boil the Bittersweet in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S*

This has been omitted in the British Pharmacopœia, and an infusion substituted; but why, we are at a loss to say; for there is no reason to suppose that the virtues of bittersweet are materially impaired by boiling; and the twigs, having a somewhat ligneous texture, require a more thorough operation of the menstruum than many other substances. Indeed, this is one of the decoctions in which we are disposed to prefer the formula of 1850, which directed that an ounce of the twigs should be boiled with a pint and a half of water to a pint.

The properties and uses of this decoction have been already detailed under the head of *Dulcamara*. The dose is from one to two fluidounces three or four times a day, or more frequently. W.

DECOCTUM GRANATI RADICIS. *Br. Decoction of Pomegranate Root.*

"Take of Pomegranate Root, fresh or dry, sliced, *two ounces* [avoirdupois]; Distilled Water *two pints* [Imperial measure]. Boil down to a pint, and strain." *Br.*

For the uses and dose of this decoction, see *Granati Radicis Cortex*. W.

DECOCTUM HÆMATOXYLI. *U. S., Br. Decoction of Logwood.*

"Take of Logwood, rasped, *a troyounce;* Water *a sufficient quantity.* Boil the Logwood in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

"Take of Logwood, in chips, *one ounce* [avoirdupois]; Cinnamon, in powder, *sixty grains;* Distilled Water *one pint.* Boil the Logwood in the Water for ten minutes, adding the Cinnamon towards the end, and strain. The product should measure sixteen [fluid]ounces." *Br.*

We prefer the old U. S. formula, which ordered an ounce of the logwood to be boiled with two pints down to a pint, and doubt much whether the wood is exhausted by a boiling of ten or fifteen minutes. The cinnamon of the Br. formula is in general a very suitable addition; but there might be circumstances under which it would be better avoided; and in this case, as in others, any addition to the simple decoction might be left to the judgment of the prescriber.

This is an excellent astringent in diarrhœa; particularly in that form of it which succeeds the cholera infantum of this climate, or occurs as an original complaint in children during summer. The dose for an adult is two fluidounces, for a child about two years old, two or three fluidrachms, repeated several times a day. A little bruised cinnamon may often be added with advantage at the end of the boiling, as directed in the British process. W.

DECOCTUM HORDEI. *U. S., Br. Decoction of Barley.*

"Take of Barley *two troyounces;* Water *a sufficient quantity.* Having washed away the extraneous matters which adhere to the Barley, boil it with half a pint of Water for a short time, and throw away the resulting liquid. Then, having poured on it four pints of boiling Water, boil down to two pints, and strain." *U. S.*

"Take of Pearl Barley *two ounces* [avoirdupois]; Distilled Water *one pint and a half* [Imperial measure]. Wash the Barley in cold water, and reject the washings; boil with the Distilled Water for twenty minutes, in a covered vessel, and strain." *Br.*

Barley water, as this decoction is usually called, is much employed as a nutritive drink in febrile and inflammatory complaints, and, from the total absence of irritating properties, is peculiarly adapted to cases in which the gastric or intestinal mucous membrane is inflamed. As the stomach of those for whom it is directed is often exceedingly delicate, and apt to revolt against anything hav-

ing the slightest unpleasantness of flavour, it is important that the decoction should be properly made; and, though the office of preparing it generally falls to nurses, yet the introduction of the process into the Pharmacopœia is not without advantage, as a formula is thus ever before the physician, by which he may give his directions, with the certainty, if obeyed, of having a good preparation. The use of the washing with cold water, and of the first short boiling, is completely to remove any mustiness, or other disagreeable flavour, which the barley may have acquired from exposure; and the British Pharmacopœia has probably erred in abandoning the second of these precautions. W.

DECOCTUM PAPAVERIS. *Br. Decoction of Poppies.*

"Take of Poppy Capsules, bruised, and freed from the seeds, *four ounces* [avoirdupois]; Distilled Water *three pints* [Imperial measure]. Boil for ten minutes, and strain. The product should measure thirty-two [fluid]ounces." *Br.*

This decoction is used as an anodyne fomentation in painful tumours, and superficial cutaneous inflammation or excoriation. It is recommended not to reject the seeds, as their oil, suspended in the water by the mucilage of the capsules, adds to the emollient virtues of the preparation. W.

DECOCTUM PAREIRÆ. *Br. Decoction of Pareira.*

"Take of Pareira, sliced, *one ounce and a half* [avoirdupois]; Distilled Water *one pint and a half* [Imperial measure]. Boil for fifteen minutes, and strain. The product should measure a pint [Imp. meas.]." *Br.*

This is apt to remain turbid after straining, but, if allowed to stand, gradually deposits insoluble matter, and then filters perfectly clear. (*Pharm. Journ.*, xiv. 491.) The dose is from one to two fluidounces three or four times a day. W.

DECOCTUM QUERCÛS ALBÆ. *U. S. Decoction of White-oak Bark.* DECOCTUM QUERCUS. *Br. Decoction of Oak Bark.*

"Take of White-oak Bark, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the White-oak Bark in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

"Take of Oak Bark [bark of Quercus pedunculata], bruised, *one ounce and a half* [avoirdupois]; Distilled Water *one pint and a half* [Imperial measure]. Boil for ten minutes in a covered vessel, and strain." *Br.*

The U. S. Pharmacopœia of 1850 directed to boil an ounce of the bruised bark with a pint and a half of water down to a pint; and we have little doubt that the result was a more complete exhaustion of the bark than by the present process.

This decoction contains the tannin, bitter principle, and gallic acid of oak bark. It affords precipitates with the decoction of Peruvian bark and other substances containing vegetable alkaloids, with solution of gelatin, and with most metallic salts, particularly those of iron. Alkaline solutions diminish or destroy its astringency. Its uses have been already detailed. The dose is a wineglassful, frequently repeated. W.

DECOCTUM SARSÆ. *Br. Decoction of Sarsaparilla.*

"Take of Jamaica Sarsaparilla, not split, *two ounces and a half* [avoirdupois]; Boiling Distilled Water *one pint and a half* [Imperial measure]. Digest the Sarsaparilla in the Water for an hour; boil for ten minutes in a covered vessel, cool, and strain. The product should measure a pint." *Br.*

An idea was long entertained that the virtues of sarsaparilla resided in its fecula, the extraction of which was, therefore, the main object of the decoction. Hence the long boiling formerly ordered by the London and Edinburgh Colleges. But this opinion is now admitted to have been erroneous. The activity of the root is believed to depend upon one or more acrid principles, soluble to a certain extent in water cold or hot, and either volatilized, or rendered inert by chemical change, at the temperature of 212°. This fact appears to be demonstrated by the expe

riments of Pope,* Hancock,† Soubeiran,‡ Beral, and others. Soubeiran macerated one portion of bruised sarsaparilla in cold water for twenty-four hours; infused another portion in boiling water, and digested with a moderate heat for two hours; boiled a third portion bruised, and a fourth unbruised, in water for two hours; and in each instance used the same relative quantities. Testing these various preparations by the taste, he found the cold and hot infusions scarcely different in this respect; and both possessed of a stronger odour and more acrid taste than the decoctions, of which that prepared with the bruised root was the strongest. Beral has proved that *sarsaparillin*, which is believed to be the active principle of the drug, is volatile. From these facts the inference is obvious, that the best method of imparting the virtues of sarsaparilla to water is either by cold or hot infusion. Digestion for some hours in water maintained at a temperature of 180°, or somewhat less, in a covered vessel, has strong testimony in its favour. Percolation in a displacement apparatus, if properly conducted, is a convenient and no doubt efficient mode of exhausting the root, so far as water will effect that object. Decoction is the worst method; and the longer it is continued, the weaker will be the preparation. Accordingly, in the edition of the U. S. Pharmacopœia for 1850, an infusion of sarsaparilla was substituted for the simple decoction, though abandoned in the present edition as superfluous. It is probable that, as in the case of the Peruvian bark, a boiling of ten or fifteen minutes might be advantageously resorted to, when circumstances require the preparation to be made in less time than is requisite for infusion. In every instance the root should be thoroughly bruised, or reduced to a coarse powder, thus obviating the necessity for a long maceration, merely to overcome the cohesion of its fibres. These principles, so far as refers to the menstruum, have been recognised by the framers of the present British Pharmacopœia, in which long boiling has been abandoned. The unsplit root, however, is ordered, from the conviction, probably, that the internal amylaceous part is inert; but there can be no doubt that the drug yields its virtues more readily when well bruised or otherwise comminuted than in the natural state.

Precipitates are produced by various substances with this decoction; but it has not been ascertained how far such substances interfere with its activity. Those which merely throw down the fecula do not injure the preparation.

The decoction of sarsaparilla may be administered in the dose of four or six fluidounces four times a day. W.

DECOCTUM SARSAPARILLÆ COMPOSITUM. *U. S.* DECOCTUM SARSÆ COMPOSITUM. *Br. Compound Decoction of Sarsaparilla.*

"Take of Sarsaparilla, sliced and bruised, *six troyounces;* Bark of Sassafras Root, sliced, Guaiacum Wood, rasped, Liquorice Root, bruised, each, *a troyounce;* Mezereon, sliced, *one hundred and eighty grains;* Water *a sufficient quantity.* Macerate with four pints of Water for twelve hours; then boil for a quarter of an hour, strain, and add sufficient Water, through the strainer, to make the decoction measure four pints." *U. S.*

"Take of Jamaica Sarsaparilla, not split, *two ounces and a half;* Sassafras, in chips, Guaiac Wood turnings, Fresh Liquorice Root, bruised, each, *a quarter of an ounce;* Mezereon *sixty grains;* Boiling Distilled Water *one pint and a half* [Imperial measure]. Digest all the ingredients in the Water for an hour; boil for ten minutes in a covered vessel; cool and strain. The product should measure a pint [Imp. meas.]." *Br.* The ounce employed in this process is the avoirdupois ounce.

* Trans. of the Medico-Chirurg. Society of London, vol. xii. p. 344.

† Trans. of the Medico-Botan. Society of London See also Journ. of the Philad. Col. of Pharm., vol. i. p. 295. The observations of Dr. Hancock are entitled to much credit, as he practised long in South America, in the neighbourhood of the best sarsaparilla regions.

‡ Journ. de Pharmacie, tom. xvi. p. 38.

This decoction is an imitation of the celebrated *Lisbon diet drink*. The sarsaparilla and mezereon are the active ingredients; the guaiacum wood imparting scarcely any of its virtues, and the sassafras and liquorice serving little other purpose than to communicate a pleasant flavour.

If prepared with good sarsaparilla, and with a due regard to the practical rules which may now be considered as established, the decoction may be used with great advantage as a gentle diaphoretic and alterative in secondary syphilis, either alone, or as an adjuvant to a mercurial course; also in certain scrofulous and other depraved conditions of the system, in chronic rheumatism, and in various obstinate cutaneous affections. The dose is from four to six fluidounces three or four times a day. The patient during its use should wear flannel next the skin, and avoid unnecessary exposure to changes of temperature.* W.

DECOCTUM SCOPARII. *Br. Decoction of Broom.*

"Take of Broom-tops, dried, *half an ounce* [avoirdupois]; Distilled Water *half a pint* [Imperial measure]. Boil for ten minutes in a covered vessel, and strain. The product should measure about eight [fluid]ounces." *Br.*

This decoction is used as an adjuvant to more powerful diuretics in dropsy. From half a pint to a pint may be taken during the day. W.

DECOCTUM SENEGÆ. *U. S. Decoction of Seneka.*

"Take of Seneka, bruised, *a troyounce;* Water *a sufficient quantity*. Boil the Seneka in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

In the British Pharmacopœia the decoction of seneka has been superseded by the infusion. (See *Infusum Senegæ.*)

This is one of the decoctions in which experience has shown that long boiling impairs the activity of the medicine; and the substitution in our Pharmacopœia of a moderate boiling, for the former direction to boil down from a pint and a half to a pint, was certainly judicious.

It is customary to add to the seneka in decoction an equal weight of liquorice root, which serves to cover its taste, and in some measure to obtund its acrimony. The virtues and practical application of seneka have been already treated of. (See *Senega.*) The dose of the decoction is about *two fluidounces* three or four times a day, or a tablespoonful every two or three hours. W.

DECOCTUM TARAXACI. *Br. Decoction of Taraxacum.*

"Take of Dried Dandelion Root, sliced and bruised, *one ounce* [avoirdupois]; Distilled Water *one pint and a half* [Imperial measure]. Boil for ten minutes, and strain. The product should measure one pint [Imp. meas.]." *Br.*

This decoction is most efficient when prepared, as in the present British Pharmacopœia, from the root alone. The dose is a wineglassful two or three times a day. (See *Taraxacum.*) W.

* The *Decoction of Zittmann* (Decoctum Zittmanni) is a preparation of Sarsaparilla much used in Germany, for similar purposes with our compound decoction of sarsaparilla; and, as it has attracted some attention in this country as a remedy in obstinate ulcerative affections, we give the formula of the Prussian Pharmacopœia, which is generally followed in its preparation.—"Take of sarsaparilla *twelve ounces;* spring water *ninety pounds*. Digest for twenty-four hours; then introduce, enclosed in a small bag, *an ounce and a half* of sugar of alum (*saccharum aluminis* seu *saccharum aluminatum*, consisting of equal parts of *powdered alum* and *the whitest sugar*), *half an ounce* of calomel, and *a drachm* of cinnabar. Boil to thirty pounds, and near the end of the boiling add of aniseed, fennel-seed, each, *half an ounce*, senna *three ounces*, liquorice root *an ounce and a half*. Put aside the liquor under the name of THE STRONG DECOCTION. To the residue add *six ounces* of sarsaparilla and *ninety pounds* of water. Boil to thirty pounds, and near the end add lemon peel, cinnamon, cardamom, liquorice, of each, *three drachms*. Strain and set aside the liquor under the name of THE WEAK DECOCTION." Mercury was detected by Wiggers in this decoction in very small proportion. It should not be prepared in metallic vessels, lest the mercurial in solution should be decomposed. The decoction may be drunk freely.

DECOCTUM UVÆ URSI. *U. S. Decoction of Uva Ursi.*

"Take of Uva Ursi *a troyounce;* Water *a sufficient quantity.* Boil the Uva Ursi in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.*

The decoction of uva ursi has been superseded, in the British Pharmacopœia, by the infusion. (See *Infusum Uvæ Ursi.*)

The preparation contains the tannin, extractive, and gallic acid of the leaves. For an account of its uses, see *Uva Ursi.* The dose is from one to two fluid-ounces three or four times a day. W.

DIGITALIUM.

Digitaline.

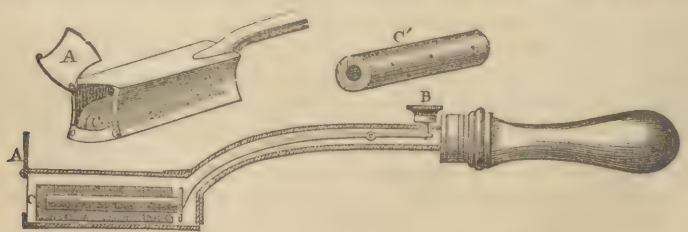
DIGITALINUM. *Br. Digitaline.*

"Take of Digitalis, in powder, *forty ounces* [avoirdupois]; Rectified Spirit, *two gallons and five fluidounces* [Imperial measure]; Distilled Water *one pint* [Imp. meas.]; Acetic Acid *half a fluidounce;* Purified Animal Charcoal *half an ounce* [avoird.]; Solution of Ammonia *a sufficiency;* Tannic Acid *one hundred and sixty grains;* Litharge, in fine powder, *a quarter of an ounce* [avoird.]; Pure Ether *a sufficiency.* Pour on the Digitalis two gallons [Imp. meas.] of the Spirit; digest at a heat of 120° for six hours; and separate the tincture by filtration and subsequent expression. Distil off the Spirit, and treat the extract with five [fluid]ounces of the Water, acidulated with the Acetic Acid. Digest with a quarter of an ounce of the Animal Charcoal, filter, and dilute the filtrate with the Water, so that it shall have the bulk of a pint. Now add the Ammonia nearly to neutralization, and afterwards the Tannic Acid dissolved in three [fluid]ounces of the Water. Wash the precipitate thus obtained with a little of the water; mix it with a small quantity of the Spirit, and carefully rub it in a mortar with the Litharge. Place the mixture in a flask, and add to it four [fluid]ounces of the Spirit; raise the temperature to 160°, and maintain it for about an hour. Then add the rest of the Animal Charcoal, filter, and remove the Spirit by distillation. Lastly, wash the residue repeatedly with the Ether." *Br.*

The above process is that of Homolle simplified by M. O. Henry, which has long occupied a place in this Dispensatory, and has been continued in the present edition, under the head of *Digitalis* in Part I. Everything has been there said which the subject seems to require. It is, we think, unfortunate that the British Council should have given officinal authority to this preparation. It has been ascertained to be a complex body, containing more or less of one or two other substances besides the proper digitaline, and consequently of uncertain strength. It would have been better to postpone the officinal recognition until the character of the active principle or principles of digitalis should be more definitely determined. Nor do we think that the Council have been happy in their title, made by affixing a Latin termination to the French. Digitalium is the proper Latin name for the active principle of digitalis, unless found to be alkaline, as it probably some time will be, when it should be called digitalia. The dose to begin with should not exceed the fiftieth or sixtieth of a grain. W.

EMPLASTRA.

Plasters.



Plasters are solid compounds intended for external application, adhesive at the temperature of the human body, and of such a consistence as to render the aid of heat necessary in spreading them. Most of them have as their basis a

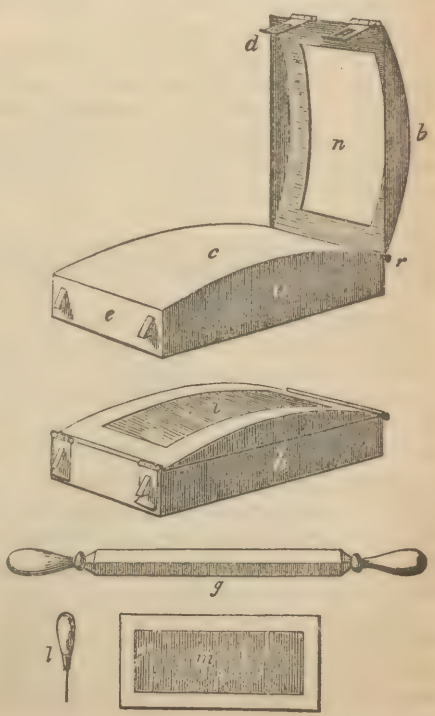
compound of olive oil and litharge, constituting the Emplastrum Plumbi of the U. S. Pharmacopœia. Those plasters which contain none of the compound of oil and litharge owe their consistence and adhesiveness to resinous substances, or to a mixture of these with wax and oleaginous matter.

In the preparation of the plasters, care is requisite that the heat employed be not sufficiently elevated to produce decomposition, nor so long continued as to drive off any volatile ingredient upon which the virtues of the Preparation may in any degree depend. After having been prepared, they are usually shaped into cylindrical rolls, and wrapped in paper to exclude the air. Plasters should be firm at ordinary temperatures, should spread easily when heated, and, after being spread, should remain soft, pliable, and adhesive, without melting, at the heat of the human body. When long kept, they are apt to change colour and to become hard and brittle; and, as this alteration is most observable upon their surface, it must depend chiefly upon the action of the air, which should therefore be as much as possible excluded. The defect may usually be remedied by melting the plaster with a moderate heat, and adding a sufficient quantity of oil to give it the due consistence.

Plasters are prepared for use by spreading them upon leather, linen, or muslin, according to the particular purposes they are intended to answer. Leather is most convenient when the application is made to the sound skin, linen or muslin when the plaster is used as a dressing to ulcerated or abraded surfaces, or with the view of bringing and retaining together the sides of wounds. The leather usually preferred is white sheep skin. A margin about a quarter or half an inch broad should usually be left uncovered, in order to facilitate the removal of the plaster, and to prevent the clothing in contact with its edges from being soiled. An accurate outline may be obtained by pasting upon the leather a piece of paper, so cut as to leave in the centre a vacant space of the required dimensions, and removing the paper when no longer needed. The same object may often be accomplished by employing two narrow rulers of sheet tin graduated in inches, and so shaped that each of them may form two sides of a rectangle. (See the figure p. 899.) These may be applied in such a manner as to enclose within them any given rectangular space, and may be fixed by weights upon the leather while the plaster is spread. For any other shape, as in the instance of plasters for the breast, pieces of tin may be employed having a vacuity within, corresponding to the required outline. The spreading of the plaster is most conveniently accomplished by means of a peculiar iron instrument employed for the purpose; though a common spatula will answer.* This may be heated by means of a spirit

* The common plaster spatula is too well known to need description. In the *Am. Journ. of Pharm.* (xxv. 29) are figures of a plaster spatula, with an instrument employed for heating it, the invention of Mr. Stockton, of Brompton, England, which present certain advantages that render them worthy of notice. We introduce the figures here, with the following description, taken from the *Lond. Pharm. Journ.* for Nov. 1853. "The blade is a hollow

case into which the heater is inserted, having a door (A) at one end, and connected at the other, by a hollow tube, with the handle. The heater (C) is supported on a lever, which passes through the hollow tube, and terminates in a thumb-button (B). By depressing the button the heater is raised so as not to be in contact with the lower part of the spatula. On



lamp. Care must be taken that the instrument be not so hot as to discolour or decompose the plaster; and special care is requisite in the case of those plasters which contain a volatile ingredient. A sufficient portion of the plaster should first be melted by the heated instrument, and, having been received on a piece of coarse stiff paper, or in a shallow tin tray open on one side, should, when nearly cool, be transferred to the leather, and applied quickly and evenly over its surface. By this plan the melted plaster is prevented from penetrating the leather, as it is apt to do when applied too hot. Before removing the paper from the edge of the plaster, if this has become so hard as to crack, the iron should be drawn over the line of junction. When linen or muslin is used, and the dimensions of the portion to be spread are large, as is often the case with adhesive plaster, the best plan is to pass the cloth "on which the plaster has been laid through a machine, formed of a spatula fixed by screws at a proper distance from a plate of polished steel." A machine for spreading plasters is described by M. Hérent in the *Journ. de Pharm.* (3*e sér.*, ii. 403).* W.

EMPLASTRUM AMMONIACI. *U. S.* *Plaster of Ammoniac.*

"Take of Ammoniac *five troyounces;* Diluted Acetic Acid *half a pint.* Dis-

removing the thumb when more heat is required, the heater is depressed, and produces the desired effect. The heater, which consists of a hollow tube of thick copper, slides on a pin which forms the termination of the lever, and which regulates its position in the box. Some heaters are perforated, to admit of their being easily heated by means of gas. The chief advantage of the spatula consists in the facility with which the heat may be regulated by means of the lever and button, which latter is quite under the control of the thumb. The box containing the heater is of brass, and, not being inserted in the fire, may be more readily kept clean than the common spatula. When several plasters are required, the heater may be removed and another inserted with facility." To the *Am. Journ. of Pharm.* (xxvi. 15) the reader is referred for the figure of another spatula which may be found convenient.—*Note to the twelfth edition.*

* Within a few years it has been customary with apothecaries to employ an apparatus, such as that here figured, for spreading quantities of plasters. An oblong rectangular block of hard wood (*a e*) has its upper surface (*c*) gently convex. To this is attached by a movable joint (at *r*) a sheet iron frame (*b*), with an opening (*n*) of the dimensions of the plaster to be spread, and clasps (*d*) at the other end, by which this may be fixed to the block. Another portion of the apparatus is a wooden measure (*m*), by which the leather is cut out, and the margin marked. The leather thus prepared is laid on the convex surface of the block (*c*); the sheet iron frame is brought down on it evenly (as at *h i*); the plaster, previously melted, is poured on the leather in the centre, and, by means of an iron instrument (*g*), previously heated by a spirit lamp, is spread uniformly over the surface, the thickness being regulated by the frame against which the iron is pressed. Any excess of plaster is thus pressed over upon the frame. The point of a sharp instrument (*l*) is then drawn along the interior edge of the frame so as to separate the plaster from it, after which the clasps are unfastened and the plaster removed.

solve the Ammoniac in the Diluted Acetic Acid, and strain; then evaporate the solution by means of a water-bath, stirring constantly until it acquires a proper consistence." *U. S.*

This plaster has been omitted in the British Pharmacopœia.

As ammoniac is not usually kept purified in our shops, the straining of the solution in the diluted acid is directed, as the most convenient method of separating impurities. Dr. Duncan remarked that the plaster, prepared in iron vessels, "acquires an unpleasant dark colour, from being impregnated with iron: whereas, when prepared in a glass or earthenware vessel, it has a yellowish-white colour, and more pleasant appearance." Care should also be used to avoid iron spatulas in its preparation, as the acetic acid acts on that metal, and discolours the plaster. The use of a moderate heat will facilitate the action of the diluted acid; and at best it is a thick creamy mass that is obtained, which requires the aid of the hand to strain it properly.

Medical Properties. The ammoniac plaster is stimulant, and is applied over scrofulous tumours and chronic swellings of the joints, to promote their resolution. It often produces a papular eruption, and sometimes occasions considerable inflammation of the skin. W.

EMPLASTRUM AMMONIACI CUM HYDRARGYRO. *U. S.*, *Br.* *Plaster of Ammoniac with Mercury.*

"Take of Ammoniac *twelve troyounces;* Mercury *three troyounces:* Olive Oil *sixty grains;* Sublimed Sulphur *eight grains.* Heat the Oil, and gradually add the Sulphur, stirring constantly until they unite; then add the Mercury, and triturate until globules cease to be visible. Boil the Ammoniac with sufficient water to cover it until they are thoroughly mixed; then strain through a hair sieve, and evaporate, by means of a water-bath, until a small portion taken from the vessel hardens on cooling. Lastly, add the Ammoniac, while yet hot, gradually to the mixture of Oil, Sulphur, and Mercury, and thoroughly incorporate all the ingredients." *U. S.*

"Take of Ammoniac *twelve ounces* [avoirdupois]; Mercury *three ounces* [avoird.]; Olive Oil *one fluidrachm;* Sulphur *eight grains.* Heat the Oil, and add the Sulphur to it gradually, stirring till they unite. With this mixture triturate the Mercury until the globules are no longer visible; and, lastly, add the Ammoniac, previously liquefied, mixing the whole carefully." *Br.*

The only use of the sulphur is to aid in the extinguishment of the mercury; as the compound formed by it with the metal is probably inert. When ammoniac not previously prepared is used, as it is not fusible by heat, it must be brought to the proper consistence by softening it in a small quantity of hot water, straining, and evaporating.

Medical Properties and Uses. This plaster unites with the stimulant power of the ammoniac the specific properties of the mercury, which is sometimes absorbed in sufficient quantity to affect the gums. It is used as a discutient in enlargement of the glands, tumefaction of the joints, nodes, and other indolent swellings, especially when dependent on a venereal taint. It is also sometimes applied over the liver in chronic hepatitis. W.

EMPLASTRUM ANTIMONII. *U. S. Plaster of Antimony.*

"Take of Tartrate of Antimony and Potassa, in fine powder, *a troyounce;* Burgundy Pitch *four troyounces.* Melt the Pitch by means of a water-bath, and strain; then add the powder, and stir them well together until the mixture thickens on cooling." *U. S.*

This is a useful formula, as it will probably supersede the former irregular methods of preparing the antimonial plaster, of which the most primitive was to sprinkle the tartar emetic in powder upon the surface of adhesive plaster, somewhat softened with heat. It affords one of the most convenient methods of ob-

taining the local pustulating effects of tartar emetic. For its effects and uses, see *Antimonii et Potassæ Tartras*, page 981. W.

EMPLASTRUM ARNICÆ. *U. S. Plaster of Arnica.*

"Take of Alcoholic Extract of Arnica *a troyounce and a half;* Resin Plaster *three troyounces.* Add the Extract to the Plaster, previously melted by means of a water-bath, and mix them." *U. S.*

These ingredients incorporate readily, and form a good plaster. The preparation was introduced into the Pharmacopœia, to enable the apothecary to meet the demand for a convenient preparation of arnica for external use. It is supposed to be useful in sprains and bruises, and sometimes probably acts beneficially by its stimulant properties in chronic rheumatism and other chronic external inflammations. (See *Arnica.*) W.

EMPLASTRUM ASSAFŒTIDÆ. *U. S. Plaster of Assafetida.*

"Take of Assafetida, Plaster of Lead, each, *twelve troyounces;* Galbanum, Yellow Wax, each, *six troyounces;* Alcohol *three pints.* Dissolve the Assafetida and Galbanum in the Alcohol by means of a water-bath, strain the liquid while hot, and evaporate to the consistence of honey; then add the Plaster and Wax previously melted together, stir the mixture well, and evaporate to the proper consistence." *U. S.*

This plaster has been omitted in the British Pharmacopœia,

The directions of the U. S. Pharmacopœia indicate the mode in which the gum-resins may be brought to the liquid state, before being incorporated with the other ingredients. Galbanum melts sufficiently by the aid of heat to admit of being strained; but this is not the case with assafetida, which must be prepared by dissolving it in a small quantity of hot water or alcohol, straining, and evaporating to the consistence of honey; and even galbanum may be most conveniently treated in the same way. Formerly these gum-resins were ordered merely to be melted and strained.

This plaster may be advantageously applied over the stomach or abdomen, in cases of hysteria attended with flatulence, and to the chest or between the shoulders in hooping-cough. W.

EMPLASTRUM BELLADONNÆ. *U. S., Br. Plaster of Belladonna.*

"Take of Alcoholic Extract of Belladonna *a troyounce;* Resin Plaster *two troyounces.* Add the Extract to the Plaster, previously melted by means of a water-bath, and mix them." *U. S.*

"Take of Extract of Belladonna *three ounces;* Soap Plaster, Resin Plaster, each, *one ounce and a half.* Melt the Plasters by the heat of a steam or water-bath; then add the Extract of Belladonna, and mix intimately." *Br.*

The most convenient method of forming this plaster is to rub the ingredients together in an earthenware mortar, placed in hot water, and then, having removed the mortar from the water-bath, to continue the trituration till the mixture cools. It was formerly prepared with the extract made from the inspissated juice of the leaves; but, in the present edition of the U. S. Pharmacopœia, the alcoholic extract has been substituted with the effect of rendering the plaster easier to be spread and more adhesive. The preparation is a useful anodyne application in neuralgic and rheumatic pains, and in dysmenorrhœa. We have seen the constitutional effects of belladonna result from its external use. W

EMPLASTRUM CALEFACIENS. *Br. Warm Plaster.*

See EMPLASTRUM PICIS CUM CANTHARIDE. *U. S.*

EMPLASTRUM CANTHARIDIS. *Br. Cantharides Plaster. Blistering Plaster.*

See CERATUM CANTHARIDIS. *U. S.*

EMPLASTRUM FERRI. *U. S.*, *Br.* EMPLASTRUM ROBORANS. *Plaster of Iron. Chalybeate Plaster. Strengthening Plaster.*

"Take of Subcarbonate of Iron *three troyounces;* Plaster of Lead *twenty-four troyounces;* Burgundy Pitch *six troyounces.* Add the Subcarbonate of Iron to the Plaster and Burgundy Pitch, previously melted together, and stir them constantly until the mixture thickens on cooling." *U. S.*

"Take of Peroxide of Iron, in fine powder, *one ounce;* Burgundy Pitch *two ounces;* Litharge Plaster *eight ounces.* Add the Peroxide of Iron to the Burgundy Pitch and Litharge Plaster, previously melted together, and stir the mixture constantly till it stiffens on cooling." *Br.*

This preparation has enjoyed some popular celebrity, under the impression that it strengthens the parts to which it is applied; whence it has derived the name of strengthening plaster. It is used in those conditions of the loins, larger muscles, and joints, which, though usually ascribed to debility, are in fact most frequently dependent on rheumatic or other chronic inflammatory affections, and, if relieved by the plaster, are so in consequence of the gentle excitation produced by it in the vessels of the skin, or of the exclusion of the air. It may also, in some instances, give relief by affording mechanical support; but neither in this, nor in any other respect can it be deemed very efficient. W.

EMPLASTRUM GALBANI. *Br. Galbanum Plaster.*

"Take of Galbanum, Ammoniac, Yellow Wax, each, *one ounce;* Litharge Plaster *eight ounces.* Melt the Galbanum and Ammoniac together, and strain. Then add them to the Litharge Plaster and Wax, also previously melted together, and mix the whole thoroughly." *Br.*

The galbanum and ammoniac are best prepared by dissolving them in a small quantity of hot water or diluted alcohol, straining the solution, and evaporating it to the proper consistence for mixing with the other ingredients. W.

EMPLASTRUM GALBANI COMPOSITUM. *U. S. Compound Plaster of Galbanum.*

"Take of Galbanum *eight troyounces;* Turpentine *a troyounce;* Burgundy Pitch *three troyounces;* Plaster of Lead *thirty-six troyounces.* To the Galbanum and Turpentine, previously melted together and strained, add first the Burgundy Pitch, and afterwards the Plaster melted over a gentle fire, and mix the whole together." *U. S.*

Before being employed in this process, the galbanum should be purified, as it often contains foreign matters which must injure the plaster. It may be freed from these by melting it with a little water or diluted alcohol, straining, and evaporating to the due consistence.

This and the preceding plaster act as an excellent local stimulant in chronic scrofulous enlargements of the glands and joints. We have employed the compound plaster in obstinate cases of this kind, which, after having resisted general and local depletion, blistering and other measures, have yielded under its use. As a discutient it is also employed in the induration which sometimes remains after the discharge of abscesses. It is said to have been useful in rickets, applied over the whole lumbar region, and has been recommended in chronic gouty and rheumatic articular affections. It should not be used in the discussion of tumours in which any considerable inflammation exists. W.

EMPLASTRUM HYDRARGYRI. *U. S.*, *Br. Mercurial Plaster.*

"Take of Mercury *six troyounces;* Olive Oil, Resin, each, *two troyounces;* Plaster of Lead *twelve troyounces.* Melt the Oil and Resin together, and, when they have become cool, rub the Mercury with them until globules of the metal cease to be visible. Then gradually add the Plaster, previously melted, and mix the whole together." *U. S.*

"Take of Mercury *three ounces;* Olive Oil *one fluidounce;* Resin *one ounce;* Litharge Plaster *six ounces.* Dissolve the Resin in the Oil with the aid of heat; let them cool; add the Mercury, and triturate till its globules disappear. Then add to the mixture the Litharge Plaster, previously liquefied, and mix the whole together." *Br.* The ounce employed in this process is the avoirdupois ounce.

The U. S. and British processes may be considered as identical in their results. The sulphuretted oil employed in the former process of the London College to facilitate the extinguishment of the mercury has been very properly abandoned.

This plaster is employed to produce the local effects of mercury upon venereal buboes, nodes, and other chronic tumefactions of the bones or soft parts, dependent on a syphilitic taint. In these cases it sometimes acts as a powerful discutient. It is frequently also applied to the side in chronic hepatitis or splenitis. In peculiarly susceptible persons, it occasionally affects the gums.

From observations made in France by M. Serres and others, it appears that the mercurial plaster of the Codex (*Emplastrum de Vigo cum Mercurio*) has the power, when applied over the eruption of smallpox, before the end of the third day from its first appearance, to check its progress, and prevent suppuration and pitting. This operation of the plaster, so far from being attended with an increase of the general symptoms, seems to relieve them in proportion to the diminution of the local affection. It is also thought that the course of the disease is favourably modified when the mercurial impression is produced upon the system. That the local effect is not ascribable to the mere exclusion of the air is proved by the fact, that the use of lead plaster was not followed by the same results. It is probable that other mercurial preparations would answer the same purpose; and the common mercurial ointment has, in our own hands, proved effectual in rendering the eruption upon the face to a considerable extent abortive, in one bad case of smallpox. But as the most successful results were obtained with the plaster above mentioned, we give the formula of the French Codex for its preparation. The weights mentioned are those of the French metrical pound. (See *table in the Appendix.*)

Emplastrum de Vigo cum Mercurio. "Take of simple plaster [lead plaster] *two pounds eight ounces;* yellow wax *two ounces;* resin *two ounces;* ammoniac, bdellium, olibanum, and myrrh, each, *five drachms;* saffron *three drachms;* mercury *twelve ounces;* turpentine [common European] *two ounces;* liquid storax *six ounces;* oil of lavender *two drachms.* Powder the gum-resins and saffron, and rub the mercury with the storax and turpentine in an iron mortar until completely extinguished. Melt the plaster with the wax and resin, and add to the mixture the powders and volatile oil. When the plaster shall have been cooled, but while it is yet liquid, add the mercurial mixture, and incorporate the whole thoroughly." This should be spread upon leather or linen cloths, and applied so as effectually to cover the part to be protected. W.

EMPLASTRUM OPII. *U. S., Br. Plaster of Opium.*

"Take of Extract of Opium *a troyounce;* Burgundy Pitch *three troyounces;* Plaster of Lead *twelve troyounces;* Water *a sufficient quantity.* Mix the Extract with three fluidounces of Water, and evaporate, by means of a water-bath, to a fluidounce and a half. Add this to the Burgundy Pitch and Plaster, melted together by means of a water-bath, and continue the heat for a short time, stirring constantly, that the moisture may be evaporated." *U. S.*

"Take of Opium, in very fine powder, *one ounce;* Resin Plaster *nine ounces.* Melt the Resin Plaster by means of a steam or water-bath; then add the Opium by degrees, and mix thoroughly." *Br.*

We decidedly prefer the extract of opium, as employed in the present U. S. process, to the opium itself of the British formula. It not only forms a better plaster, but, being soluble, is more likely to produce the anodyne effect desired, by being brought by the perspiration to the liquid state necessary for its ab-

sorption. The use of water in the former process is also an advantage, as it enables the opium to be more thoroughly incorporated with the other ingredients; but care should be taken that the moisture be well evaporated.

The opium plaster is thought to relieve rheumatic and other pains in the parts to which it is applied. W.

EMPLASTRUM PICIS. *Br. Pitch Plaster.*

"Take of Burgundy Pitch, *twenty-six ounces;* Common Frankincense [Terebinthina, U. S.] *thirteen ounces;* Resin, Yellow Wax, each, *four ounces and a half;* Expressed Oil of Nutmeg *one ounce;* Olive Oil *two fluidounces;* Water *two fluidounces.* Add the Oils and the Water to the Frankincense, Burgundy Pitch, Resin, and Wax, previously melted together; then, constantly stirring, evaporate to a proper consistence." *Br.* The ounce used in this process is the avoirdupois ounce.

This is a rubefacient plaster, applicable to catarrhal and other pectoral affections, chronic inflammation of the liver, and rheumatic pains in the joints and muscles. It often keeps up a serous discharge, which requires that it should be frequently renewed. The irritation which it sometimes excites is so great as to render its removal necessary. W.

EMPLASTRUM PICIS BURGUNDICÆ. *U. S. Plaster of Burgundy Pitch.*

"Take of Burgundy Pitch *seventy-two troyounces;* Yellow Wax *six troyounces.* Melt them together, strain, and stir constantly until they thicken on cooling." *U. S.*

In this formula, the object of the wax is simply to give a proper consistence to the Burgundy pitch, and to prevent it from breaking in cold weather. W.

EMPLASTRUM PICIS CANADENSIS. *U. S. Plaster of Canada Pitch. Hemlock Pitch Plaster.*

"Take of Canada Pitch *seventy-two troyounces;* Yellow Wax *six troyounces.* Melt them together, strain, and stir constantly until they thicken on cooling." *U. S.*

The yellow wax, in this preparation, answers the same purpose as in the Burgundy Pitch Plaster, and is even more necessary, in order to give additional consistence to the Canada Pitch, which, when pure, is somewhat too soft, at the temperature of the body, for convenient application. W.

EMPLASTRUM PICIS CUM CANTHARIDE. *U. S.* EMPLASTRUM CALEFACIENS. *Br. Plaster of Pitch with Cantharides. Warming Plaster.*

"Take of Burgundy Pitch *forty eight troyounces;* Cerate of Cantharides *four troyounces.* Melt them together by means of a water-bath, and stir constantly until the mixture thickens on cooling." *U. S.*

"Take of Cantharides, in coarse powder, *four ounces;* Boiling Water *one pint* [Imperial measure]; Expressed Oil of Nutmeg, Yellow Wax, Resin, each, *four ounces;* Soap Plaster *three pounds and a quarter;* Resin Plaster *two pounds.* Infuse the Cantharides in the boiling Water for six hours; squeeze strongly through calico, and evaporate the expressed liquid by a steam or water-bath till reduced to one-third. Then add the other ingredients, and melt in a steam or water-bath, stirring well until the whole is thoroughly mixed." *Br.* The weights employed in this process are the avoirdupois.

This plaster is an excellent rubefacient, more active than Burgundy pitch, yet in general not sufficiently so to produce vesication. As prepared by the former U. S. process, it occasionally blistered; and the proportion of cantharides has, therefore, been considerably diminished in the present formula; but, while such a reduction may render the plaster insufficiently active in most cases, it does not entirely obviate the objection · as the smallest proportion of flies would vesi-

cate in certain persons, and even the Burgundy pitch alone sometimes produces the same effect. In whatever mode, therefore, this plaster may be prepared, it cannot always answer the expectations which may be entertained; and the only plan, when the skin of any individual has been found to be very susceptible, is to accommodate the proportions to the particular circumstances of the case. Much, however, may be accomplished by care in the preparation of the plaster, towards obviating its tendency to blister. If the flies of the *Ceratum Cantharidis* have been coarsely pulverized, the larger particles coming in contact with the skin, will exert upon the particular part to which they may be applied their full vesicatory effect, while, if reduced to a very fine powder, they would be more thoroughly enveloped in the other ingredients, and thus have their strength much diluted. Hence the cerate, when used as an ingredient of the warming plaster, should contain the cantharides as minutely divided as possible; and, if that usually kept is not in the proper state, a portion should be prepared for this particular purpose. A good plan, we presume, would be to keep the cerate used in this preparation, for a considerable time, at the temperature of 212°, and then strain it so as to separate the flies. (See *Ceratum Cantharidis.*) The mode frequently pursued of preparing the warming plaster by simply sprinkling a very small proportion of powdered flies upon the surface of Burgundy pitch is altogether objectionable. The U. S. process is that of the old Dublin Pharmacopœia. We strongly approve of that portion of the British process which uses an inspissated infusion of the flies, as an equable distribution of these is thus ensured.

The warming plaster is employed in chronic rheumatism, and various chronic internal diseases attended with inflammation or an inflammatory tendency; such as catarrh, asthma, pertussis, phthisis, hepatitis, and the sequelæ of pleurisy and pneumonia. W.

EMPLASTRUM PLUMBI. *U. S.* Emplastrum Lithargyri. *Br.* *Plaster of Lead. Litharge Plaster.*

"Take of Oxide of Lead [Litharge], in fine powder, *thirty troyounces;* Olive Oil *fifty-six troyounces;* Water *a sufficient quantity.* Sift the Oxide of Lead into the Oil, contained in a suitable vessel, of a capacity equal to twice the bulk of the ingredients. Then add half a pint of boiling Water, and boil the whole together until a plaster is formed; adding from time to time, during the process, a little boiling Water, as that first added is consumed." *U. S.*

"Take of Litharge, in very fine powder, *four pounds:* Olive Oil *one gallon;* Water *three pints and a half.* Boil all the ingredients together gently in a copper pan over a clear fire, and keep simmering for four or five hours, stirring constantly, until the Oil and Litharge acquire a proper consistence for a plaster, adding more Water during the process if necessary." *Br.* The weights used in this process are the avoirdupois, and the measures the Imperial.

The importance of this plaster, as the basis of most of the others, requires a somewhat detailed account of the principles and manner of its preparation.

It was formerly thought that the oil and oxide of lead entered into direct union, and that the presence of water was necessary only to regulate the temperature, and prevent the materials from being decomposed by heat. The discovery, however, was afterwards made, that this liquid was essential to the process; and that the oil and oxide alone, though maintained at a temperature of 220°, would not combine; while the addition of water, under these circumstances, would produce their immediate union. It was now supposed that the oil was capable of combining only with the hydrated oxide of lead, and that the use of the water was to bring the oxide into that state; and, in support of this opinion, the fact was advanced that the hydrated oxide of lead and oil would form a plaster, when heated together without any free water. But, since the general reception of Chevreul's views in relation to oils, and their combinations with alkalies and other metallic oxides, the former opinions have been abandoned;

and it is now admitted that the preparation of the lead plaster affords a genuine example of saponification, as explained by that chemist. A reaction takes place between the oil and water, resulting in the development of a sweetish substance called *glycerin*, and of two acid bodies, the *oleic* and *margaric acids*, to which, when animal fat is employed instead of olive oil, a third is added, namely the *stearic*. The plaster is formed by a union of these acids with the oxide, and, prepared according to the directions of the Pharmacopœias, is in fact an oleo-margarate of lead. The glycerin remains dissolved in the water, or mechanically mixed with the plaster. That such is the correct view of the nature of this compound is evinced by the fact, that, if the oxide of lead be separated from the plaster by digestion at a moderate heat in very dilute nitric acid, the fatty matter which remains will unite with litharge with the greatest facility, without the intervention of water. According to a more recent chemical view, the fixed oils are compounds of the oily acids mentioned and *oxide of glyceryl*. When boiled with the oxide of lead and water, the oily acids combine with the metallic oxide to form the plaster, and the oxide of glyceryl takes an equivalent of water and becomes glycerin. *Glyceryl* is a hypothetical compound of carbon and hydrogen (C_6H_7), which unites with five equivalents of oxygen to form oxide of glyceryl ($C_6H_7O_5$), also a hypothetical substance, and additionally with an equivalent of water to form glycerin ($C_6H_7O_5+HO$).

Other oleaginous substances and other metallic oxides are susceptible of the same combination, and some of them form compounds having the consistence of a plaster; but, according to *M. Henry*, of Paris, no oily matter except animal fat can properly be substituted for olive oil, and no metallic oxide, not even one of the other oxides of lead, for litharge. He ascertained, moreover, that the English litharge is preferable for the formation of lead plaster to the German. From more recent experiments of Soubeiran, it appears that massicot or even minium may be substituted for litharge, and a plaster of good consistence be obtained; but that a much longer time is required for completing the process than when the officinal formula is followed. When minium is used, the necessity for its partial deoxidation renders a longer continuance of the process necessary than with massicot. According to M. Davallon, Professor in the School of Medicine and Pharmacy at Lyons, it is important that the olive oil employed should be pure; for when adulterated, as it frequently is in commerce, it yields an imperfect product. Mr. N. S. Thomas prepared a good plaster by substituting lard for olive oil, in the proportion of eight pounds of lard to five of litharge (*Am. Journ. of Pharm.*, xix. 175); and we are told that it is a common practice, in this country, to make lead plaster with a mixture of lard oil and olive oil.

Lead plaster has also been prepared by double decomposition between soap and acetate or subacetate of lead; but the results have not been so advantageous as to lead to the general adoption of this process. For particular information on the subject, the reader is referred to the *American Journal of Pharmacy* (ix. 127), and to the *Journal de Pharmacie* (xxiii. 163 and 322.)*

Preparation. The vessel in which the lead plaster is prepared should be of such a size that the materials will not occupy more than two-thirds of its capacity. The oil should be first introduced, and the litharge then sprinkled in by means of a sieve, the mixture being constantly stirred with a spatula. The par-

* M. de Mussy, physician of the hospital *de la Pitié*, having witnessed inconveniences from lead plaster in consequence of the absorption of the lead, substituted for it a plaster with a basis of oxide of zinc, which he has found to answer very well in practice. It cannot be made by direct combination of the oxide; and it is necessary to have recourse to the method of double decomposition. Solutions of white olive oil soap and of sulphate of zinc being mixed, a copious precipitate takes place of oleo-margarate of zinc, which, after being washed and dried, may be combined with resins, oil, and wax, to give it the necessary consistence. This preparation, however, is not likely to supersede the officinal. (*Journ. de Pharm.*, xxvii. 100.)—*Note to the eleventh edition.*

ticles of the oxide are thus prevented from coalescing in small masses, which the oil would not easily penetrate, and which would therefore delay the process. While the water exerts an important chemical agency in the changes which occur, it is also useful by preventing too high a temperature, which would decompose the oil, and cause the reduction of the oxide. The waste must, therefore, be supplied by fresh additions as directed in the process; and the water added for this purpose should be previously heated, as otherwise it would not only delay the operation, but by producing explosion might endanger the operator. During the continuance of the boiling, the material should be constantly stirred, and the spatula should be repeatedly passed along the bottom of the vessel, from side to side, so as to prevent any of the oxide, which is disposed by its greater density to sink to the bottom, from remaining in that situation. The materials swell up considerably, in consequence partly of the vaporization of the water, partly of the escape of carbonic acid gas, which is liberated by the oily acids from some carbonate of lead usually contained in the litharge. The process should not be continued longer than is sufficient to produce complete union of the ingredients, and this may be known by the colour and consistence of the mass. The colour of the litharge gradually becomes paler, and at length almost white when the plaster is fully formed. The consistence increases with the progress of the boiling, and is sufficiently thick, when a portion of the plaster, taken out and allowed to cool upon the end of a spatula, or thrown into cold water, becomes solid, without adhering in this state to the fingers. The portion thus solidified should not present, when broken, any red points, which would indicate the presence of a portion of uncombined litharge. When the plaster is formed, it should be removed from the fire, and after a short time cold water should be poured upon it. Portions should then be detached from the mass, and, having been well kneaded under water, in order to separate the viscid solution of glycerin contained in the interior, should be formed into cylindrical rolls, and wrapped in paper. Such at least has been the course of proceeding usually recommended. But M. Davallon maintains that the presence of glycerin in the plaster is useful by keeping it in a plastic state, and that washing and kneading are injurious, the former by removing the glycerin, the latter by introducing particles of air and moisture into the mass, which is thus rendered more disposed to rancidity. (*Am. Journ. of Pharm.*, xv. 274, from *Journ. de Chim. Méd.*) By employing steam heat in the preparation of this plaster, the risk of burning it is avoided. For a good arrangement for this purpose, see *Mohr and Redwood's Pharmacy*, edited by Prof. Procter, p. 420.

Medical Properties and Uses. This plaster, which has long been known under the name of *diachylon*, is used as an application to excoriated surfaces, and to slight wounds, which it serves to protect from the action of the air. It may also be beneficial by the sedative influence of the lead which enters into its composition. A case is on record in which lead colic resulted from its long-continued application to a large ulcer of the leg. (*Am. Journ. of Med. Sci.*, xxiii. 246.) Its chief use is in the preparation of other plasters. While in its yet incomplete state, it is used in the preparation of glycerin.*

* *Logan's Plaster.* Take of Litharge, Carbonate of Lead, each, *a pound;* Castile Soap *twelve ounces;* Butter (fresh) *four ounces;* Olive Oil *two and a half pints;* Mastic, in powder, *two drachms.* It is to be understood that the pound and ounce are of the avoirdupois weight. Having mixed the Soap, Oil, and Butter, add the Litharge, and boil the mixture gently, constantly stirring, for an hour and a half, or until it shall assume a pale-brown colour; then increase the heat somewhat, and continue to boil, until a portion of the liquid, dropped on a smooth board, is found not to adhere to it on cooling; then remove it from the fire, and mix the mastic with it. Logan's plaster has long been in popular use in Philadelphia, and is considerably employed by regular practitioners, as a protective and discutient application.

Plaster of Carbonate of Lead. This was originally introduced into our Pharmacopœia as a

Off. Prep. Emplastrum Assafœtidæ, *U. S.;* Emp. Ferri; Emp. Galbani, *Br.;* Emp. Galbani Compositum, *U. S.;* Emp. Hydrargyri; Emp. Opii, *U. S.;* Emp. Resinæ; Emp. Saponis. W.

EMPLASTRUM RESINÆ. *U. S., Br. Resin Plaster. Adhesive Plaster.*

"Take of Resin, in fine powder, *six troyounces;* Plaster of Lead *thirty-six troyounces.* To the Plaster, melted over a gentle fire, add the Resin, and mix them." *U. S.*

"Take of Resin, in powder, *four ounces;* Litharge Plaster *two pounds;* Hard Soap, in powder, *two ounces.* To the Litharge Plaster, previously melted with a gentle heat, add the Resin and Soap, first liquefied, and heat them until they are thoroughly mixed." *Br.* The weights here referred to are the avoirdupois.

This preparation differs from the lead plaster in being more adhesive and somewhat more stimulating. It is the common adhesive plaster of the shops, and is much employed for retaining the sides of wounds in contact, and for dressing ulcers according to the method of Baynton, by which the edges are drawn towards each other, and a firm support is given to the granulations. As prepared by the Dublin College it contained soap, which gave it greater pliability, and rendered it less liable to crack in cold weather, without impairing its adhesiveness; and the process of that College has been adopted in the British Pharmacopœia. It is usually spread upon muslin; and the spreading is best accomplished, on a large scale, by means of a machine, as described in the general observations upon plasters. It is kept in the shops ready spread; but, as the plaster becomes less adhesive by long exposure to the air, the supply should be frequently renewed. When the skin is very delicate, it occasionally excites some irritation, and, under these circumstances, a plaster may be substituted containing a smaller proportion of resin. That originally employed by Baynton contained only six drachms of resin to the pound of lead plaster. To obviate the same evil, M. Herpin recommends the addition of tannate of lead, the proportion of which, when adhesiveness is required in the plaster, should not exceed one-twentieth, but, under other circumstances, may be increased to one-twelfth. (*Bullet. de Thérap.*, xlviii. 155.)

In order to render the plaster more adhesive, and less brittle in cold weather, it is customary with many apothecaries to employ a considerable proportion of Burgundy pitch or turpentine in its preparation; but these additions are objectionable, as they greatly increase the liability of the plaster to irritate the skin, and thus materially interfere with the purposes for which the preparation was chiefly intended.*

substitute for *Mahy's plaster*, at one time much employed in some parts of the United States; but was omitted in the edition of 1840. It is a good application to surfaces inflamed or excoriated by friction; and may be resorted to with advantage in those troublesome cases of cutaneous irritation, and even ulceration, which are apt to occur upon the back and hips during long continued confinement to one position. We give the process as contained in the Pharmacopœia of 1830. "Take of Carbonate of Lead *a pound;* Olive Oil *two pints;* Yellow Wax *four ounces;* Lead plaster *a pound and a half;* Florentine Orris, in powder, *nine ounces.* Boil together the Oil and Carbonate of Lead, adding a little water, and constantly stirring, till they are thoroughly incorporated; then add the Wax and Plaster, and, when these are melted, sprinkle in the Orris, and mix the whole together." By this process, a good plaster may be prepared, rather too soft at first, but soon acquiring the proper consistence.

* An adhesive plaster, exempt from oxide of lead, is prepared by Pettenkofer. It consists of calcareous soap incorporated with turpentine and suet, and may be prepared in the following manner. A solution of soap is decomposed by a solution of chloride of calcium. The precipitate, having been expressed and dried, is powdered with half its weight of turpentine dried by heat; and the mixture is melted along with an eighth part of suet, in boiling water. The mixture is boiled until the mass melts into a homogeneous fluid, when it is worked by the hand, in the ordinary manner, in cold water. Should portions of the calcareous soap not melt, they should be separated by straining through flannel. (*Journ. de Pharm.*, 3e *sér.*, x. 358, from *Repertorium für die Pharm.*, xii. 40.)

Off. Prep. Emplastrum Arnicæ, *U. S.;* Emplastrum Belladonnæ; Emplastrum Calefaciens, *Br.;* Emplastrum Opii, *Br.* W.

EMPLASTRUM SAPONIS. *U. S., Br. Soap Plaster.*

"Take of Soap, sliced, *four troyounces;* Plaster of Lead *thirty-six troyounces;* Water *a sufficient quantity.* Rub the Soap with Water until brought to a semi-liquid state; then mix it with the Plaster previously melted, and boil to the proper consistence." *U. S.*

"Take of Hard Soap, in powder, *six ounces;* Litharge Plaster *two pounds and a quarter;* Resin, in powder, *one ounce.* To the Litharge Plaster, melted by a gentle heat, add the Soap and the Resin, first liquefied; then, constantly stirring, evaporate to a proper consistence." *Br.* The avoirdupois weights are used in this process.

The present U. S. formula is an improvement upon that of a former edition of the Pharmacopœia. The proportion of soap in the old process was so large as to render the plaster friable. It has been diminished from six to four ounces. Besides, by the present mode of proceeding, it is more thoroughly incorporated with the plaster. The same end of greater plasticity is accomplished, in some degree, in the British process by the resin.

Soap plaster is considered discutient, and is sometimes used as an application to tumours.

ENEMATA.

Clysters.

These can scarcely be considered proper objects for officinal direction; but, having been introduced into the former British Pharmacopœias, and retained in the present, the plan of this work requires that they should be noticed. They are substances in the liquid form, intended to be thrown up the rectum, with the view either of evacuating the bowels, of producing the peculiar impression of a remedy upon the lower portion of the alimentary canal and neighbouring organs, or of acting on the system generally through the medium of the surface to which they are applied. They are usually employed to assist the action of remedies taken by the mouth, or to supply their place when the stomach rejects them, or is insensible to their impression. Sometimes they are preferably used when the seat of the disorder is in the rectum or its vicinity. As a general rule, three times as much of any remedy is required to produce a given impression by enema, as when taken into the stomach; but this rule should be acted on with caution, as the relative susceptibilities of the stomach and rectum are not the same in all individuals; and, with regard to all very active remedies, the best plan is to administer less than the stated proportion. Attention should also be paid to the fact, that, by the frequent use of a medicine, the susceptibility of the stomach may be in some measure exhausted, without a proportionate diminution of that of the rectum.

When the object is to evacuate the bowels, the quantity of liquid administered should be considerable; for an adult from ten fluidounces to a pint; for a child of eight or ten years, half that quantity; for an infant within the year, from one to three fluidounces. Much larger quantities of mild liquids may sometimes be given with safety and advantage; as the bowels will occasionally feel the stimulus of distension, when insensible to irritating impressions.

When the design is to produce the peculiar impression of the remedy upon the neighbouring parts, or on the system, it is usually desirable that the enema should be retained; and the vehicle should therefore be bland, and as small in

quantity as is compatible with convenient administration. A solution of starch, flaxseed tea, or other mucilaginous fluid should be selected, and the quantity should seldom exceed two or three fluidounces. In every case, the patient should be instructed to resist any immediate disposition to discharge the injected fluid; and his efforts to retain it should be assisted, if necessary, by pressure with a warm folded towel upon the fundament. The best instrument for administering enemata is an accurate metallic syringe. W.

ENEMA ALOES. *Br. Enema of Aloes.*

"Take of Aloes *forty grains;* Carbonate of Potash *fifteen grains;* Mucilage of Starch *ten fluidounces.* Mix, and rub together." *Br.*

This is intended as a formula for the use of aloes in cases of ascarides in the rectum, and of amenorrhœa attended with constipation. W.

ENEMA ASSAFŒTIDÆ. *Br. Enema of Assafetida.*

"Take of Tincture of Assafetida *six fluidrachms;* Mucilage of Starch *six fluidounces.* Mix." *Br.*

This is carminative and antispasmodic as well as laxative. We should, however, prefer a preparation consisting of the gum-resin rubbed up with water; as the alcohol of the tincture might in some instances prove injurious. The whole quantity directed may be administered at once. W.

ENEMA MAGNESIÆ SULPHATIS. *Br. Enema of Sulphate of Magnesia.* ENEMA CATHARTICUM. *Ed., Dub. Cathartic Clyster.*

"Take of Sulphate of Magnesia *one ounce* [avoirdupois]; Olive Oil *one fluidounce;* Mucilage of Starch *fifteen fluidounces.* Dissolve the Sulphate of Magnesia in the Mucilage, add the Oil, and mix." *Br.*

The laxative enema, most commonly employed in this country, consists of a tablespoonful of common salt, two tablespoonfuls of lard or olive oil, the same quantity of molasses, and a pint of warm water. It has the advantage of consisting of materials which are always at hand in families, and is in all respects equal to the officinal preparation. W.

ENEMA OPII. *Br. Enema of Opium.* ENEMA OPII vel ANODYNUM. *Ed. Anodyne Enema.*

"Take of Tincture of Opium *half a fluidrachm;* Mucilage of Starch *two fluidounces.* Mix." *Br.*

This formula is unobjectionable. It must have happened to every one in the habit of prescribing opium in this way, to have seen a much greater effect produced by a certain amount of laudanum injected into the rectum than by one-third of the quantity swallowed. The fluidrachm contains at least one hundred drops of laudanum of the ordinary size, and not less than one hundred and twenty as they are often formed. From twenty to twenty-five drops are usually considered as a medium dose by the mouth; so that sixty drops, equivalent to about thirty minims, are abundantly sufficient by enema. As the object is that the enema should remain in the rectum, the smaller the quantity of the vehicle the better; and a mucilaginous fluid is preferable to water, as it involves the tincture, and prevents the irritation of the alcohol before the opium begins to take effect. The ordinary anodyne enema, employed in this country, consists of about sixty drops of laudanum and one or two fluidounces of flaxseed tea or solution of starch, conforming precisely with the present British formula.

This is an admirable remedy in obstinate vomiting, strangury from blisters, painful affections of the kidneys, bladder, and uterus, and in the tenesmus of dysentery. It may also frequently be employed to produce the effects of opium upon the system, when circumstances prevent the administration of that medicine by the mouth. W.

ENEMA TABACI. *Br.* *Enema of Tobacco.*

"Take of Leaf Tobacco *twenty grains;* Boiling Water *eight fluidounces* Infuse in a covered vessel, for half an hour, and strain." *Br.*

The whole quantity is to be given at once. The dose is somewhat less than that usually employed in this country. (See *Infusum Tabaci.*) W.

ENEMA TEREBINTHINÆ. *Br.* *Enema of Turpentine.*

"Take of Oil of Turpentine *one fluidounce;* Mucilage of Starch *fifteen fluidounces.* Mix." *Br.*

For the dose of this preparation, see *Oleum Terebinthinæ.* W.

EXTRACTA.

Extracts.

Extracts, as the term is employed in the Pharmacopœias, are solid substances, resulting from the evaporation of the solutions of vegetable principles, obtained either by exposing the vegetable to the action of a solvent, or by expressing its juice in the recent state. A distinction was formerly made between those prepared from the infusions, decoctions, or tinctures, and those from the expressed juices of plants, the former being called *Extracta*, the latter *Succi Spissati;* but the distinction has been generally abandoned. There is no such essential difference between these two sets of preparations as to require that they should be separately classed; and something is gained in the simplicity of nomenclature, as well as of arrangement, which results from their union. We shall consider them under the same head, taking care, however, to detail distinctly whatever is peculiar in the mode of preparing each.

The composition of extracts varies with the nature of the vegetable, the character of the solvent, and the mode of preparation. The object is generally to obtain as much of the active principle of the plant, with as little of the inert matter as possible; though sometimes it may be desirable to separate two active ingredients from each other, when their effects upon the system are materially different; and this may be accomplished by employing a menstruum which, while it dissolves one, leaves the other untouched. The proximate principles most commonly present in extracts are gum, sugar, starch, tannin, extractive, colouring matter, salts, and the peculiar principles of plants; to which, when a spirituous solvent is employed, may usually be added resinous substances, fatty matter, and frequently more or less essential oil; gum and starch being excluded when the menstruum is pure alcohol. Of these substances, as well as of others which, being soluble, are sometimes necessarily present in extracts, we have taken occasion to treat under various heads in the Materia Medica. There is one, however, which, from its supposed almost uniform presence in this class of preparations, and from the influence it is thought to exert upon their character, deserves particular consideration in this place. We allude to *extractive*, or, as it is sometimes called, *extractive matter.*

It has long been observed that in most vegetables there is a substance, soluble both in water and alcohol, which, in the preparation of extracts, undergoes chemical change during the process of evaporation, imparting to the liquid, even if originally limpid, first a greenish, then a yellowish-brown, and ultimately a deep-brown colour, and becoming itself insoluble. This substance, originally called *saponaceous matter* by Scheele, afterwards received the more expressive name of *extractive*, derived from its frequent presence in extracts. Its existence as a distinct principle is denied, or at least doubted by some chemists, who consider the phenomena supposed to result from its presence, as depending upon the mutual reaction of other principles; and, in relation to Peruvian bark, it appears to have been proved that the insoluble matter which forms during its decoction

in water is a compound of starch and tannin. A similar compound must also be formed in other cases when these two principles coexist; but they are not always present in the same vegetable, nor can all the changes which have been attributed to extractive be accounted for by their union, even when they are present; so that, till further light is shed on the subject, it is best to admit the existence of a distinct substance, which, though not the same in all plants, possesses sufficient identity of character to be entitled, like sugar, resin, &c., to a distinctive name. The most interesting property of extractive is its disposition to pass, by the influence of atmospheric air at a high temperature, into an insoluble substance. If a vegetable infusion or decoction be evaporated in the open air to the consistence of an extract, then diluted, filtered, and again evaporated, and the process repeated so long as any insoluble matter is formed, the whole of the extractive will be separated from the liquid, while the other ingredients may remain. If chlorine be passed through an infusion or decoction, a similar precipitate is formed with much greater rapidity. The change is usually ascribed to the absorption of oxygen by the extractive, which has, therefore, been called, in its altered condition, oxidized extractive; but De Saussure ascertained that, though oxygen is absorbed during the process, an equal measure of carbonic acid gas is given out, and the oxygen and hydrogen of the extractive unite to form water in such a manner as to leave the principle richer in carbon than it was originally. The name of oxidized extractive is, therefore, obviously incorrect; and Berzelius proposed to substitute for it that of *apotheme*, synonymous with deposit. According to Berzelius, apotheme is not completely insoluble in water, but imparts a slight colour to that liquid when cold, and is rather more soluble in boiling water, which becomes turbid upon cooling. It is still more soluble in alcohol, and is freely dissolved by solutions of the alkalies and alkaline carbonates, from which it is precipitated by acids. It has a great tendency, when precipitated from solutions, to unite with other principles, and to carry them along with it; thus acquiring properties somewhat different according to the source from which it is obtained. In this way, also, even when the extractive of a plant is itself medicinally inert, its conversion into apotheme may be injurious by causing a precipitation of a portion of the active principle; and, in practical pharmaceutic operations, this change should always, if possible, be avoided. With these preliminary views, we shall proceed to the consideration of the practical rules necessary to be observed in the preparation of extracts. We shall treat of the subject under the several heads of, 1. the extraction of the soluble principles from the plant; 2. the method of conducting the evaporation; 3. the proper condition of extracts, the changes they are liable to undergo, and the best method of preserving them; and 4. the general directions of the several Pharmacopœias in relation to them.

1. *Extraction of the Soluble Principles.*

There are two distinct modes of obtaining, in a liquid state, the principles which we wish to extract; 1. by expression alone; 2. by the agency of a solvent, with or without expression.

1. *By Expression.* This method is applicable to recent vegetables. All plants cannot be usefully treated in this way, as many have too little juice to afford an appreciable quantity upon pressure, and of the succulent a considerable portion do not yield all their active principles with their juice. Succulent fruits, and various acrid and narcotic plants, are proper subjects for this treatment. The plants should be operated upon, if possible, immediately after collection. Mr. Battley, of London, recommends that, if not entirely fresh, they should be revived by the immersion of the stalks in water for twelve or eighteen hours, and those only used which recover their freshness by this management. They should

then be cut into pieces, and bruised in a stone mortar till brought to a pulpy consistence. When the plant is not very succulent, it is necessary to add a little water during this part of the process, in order to dilute the juice. After sufficient contusion, the pulp is introduced into a linen or canvas bag, and the liquid parts expressed. Mr. Brande states that light pressure only should be employed; as the extract is thus procured greener, of a less glutinous or viscid consistence, and, in his opinion, more active than when considerable force is used in the expression. (*Manual of Pharmacy.*) The juice thus obtained is opaque and usually green, in consequence of the presence of green wax or chlorophyll, and of a portion of the undissolved vegetable fibre in minute division. By heating the juice to about 160°, the albumen contained in it coagulates, and, involving the chlorophyll and vegetable fibre, forms a greenish precipitate. If the liquid is now filtered, it becomes limpid and nearly colourless, and is prepared for evaporation. The clarification, however, is not absolutely necessary, and is generally neglected. Sometimes the precipitate carries with it a considerable portion of the active principle; in which case it should be subsequently incorporated with the juice, when reduced by evaporation to the consistence of syrup. Ether added to the expressed juices of plants enables them to be kept long without injurious change. M. Lepage, of Gisors, France, has kept the juice of belladonna in this way more than 10 years, and found it, at the end of that time, to yield an extract, identical in physical, chemical, and physiological properties with that obtained from the fresh juice. If this fact is found to be of general applicability, it will be of considerable importance, as enabling the pharmaceutist to supply himself, at pleasure, with extracts to be relied on, without reference to the season. (*Journ. de Pharm.*, Mai, 1863, p. 361.)

2. *By Solution.* The active principles of dried vegetables can be extracted only by means of a liquid solvent. The menstruum usually employed is either water or alcohol, or a mixture of the two. Water, on account of its cheapness, is always preferred, when circumstances do not strongly call for the use of alcohol. It has the advantage, moreover, that it may be assisted in its action, if necessary, by a higher degree of heat than the latter. Pump water is often unfit for the purpose, in consequence of the quantity of its saline matter, which, in some instances, may exert an unfavourable influence on the active principle, and must always be left in the extract. Rain, river, or distilled water should be preferred. Alcohol is employed when the principles to be extracted are insoluble, or but slightly soluble in water, as in the case of the resins; when it is desirable to avoid in the extract inert substances, such as gum and starch, which are dissolved by water and not by alcohol; when the heat required to evaporate the aqueous solution would dissipate or decompose the active ingredients of the plant, as the volatile oils and the active principle of sarsaparilla; when the reaction of the water itself upon the vegetable principles is injurious; and, finally, when the nature of the substance to be exhausted requires so long a maceration in water as to endanger spontaneous decomposition. The watery solution requires to be soon evaporated, as this fluid rather promotes than counteracts chemical changes; while an alcoholic tincture may be preserved unaltered for an indefinite period. An addition of alcohol to water is sufficient to answer some of the purposes for which the former is preferable; and the employment of both fluids is essential, when the virtues of the plant reside in two or more principles, all of which are not soluble in either of these menstrua. In this case it is usually better to submit the vegetable to the action of the two fluids successively, than of both united. Extracts obtained by the agency of water are called *watery* or *aqueous extracts;* those by means of alcohol, undiluted or diluted, *alcoholic* or *spirituous extracts.*

The method of preparing the solution is not a matter of indifference. The vegetable should be thoroughly bruised, or reduced to a coarse powder, so as to

allow the access of the solvent to all its parts, and yet not so finely pulverized as to prevent a ready precipitation of the undissolved and inactive portion. When water is employed, it has been customary to boil the medicine for a considerable time, and, if the first portion of liquid does not completely exhaust it, to repeat the operation with successive portions, till the whole of the active matter is extracted. This may be known by the sensible properties of the liquid, and by its influence upon reagents. But the boiling temperature produces the decomposition of many vegetable principles, or at least so modifies them as to render them inert; and the extracts prepared by decoction are usually less efficient than those made with a less degree of heat. From numerous experiments upon extracts, Orfila concluded that their virtues were less in proportion to the heat employed. It has, therefore, been recommended to substitute for decoction the process of maceration, digestion, or hot infusion; in the first of which the liquid acts without heat, in the second is assisted by a moderately increased temperature sustained for a considerable time, and in the third is poured boiling hot upon the vegetable matter, and allowed to stand for a short period in a covered vessel. When the active principles are readily soluble in cold water, *maceration* is often preferable to the other modes, as starch, which is inert, is thus left behind; but in many instances the preparation would spoil before the extraction would be completed. By *digestion*, though the solvent power of water is moderately increased, the advantage is often more than counterbalanced by the increased disposition to spontaneous decomposition. *Hot infusion*, therefore, is to be preferred where the vegetable does not readily yield its virtues to cold water. It has the advantage, moreover, in the case of albuminous substances, that the albumen is coagulated, and thus prevented from increasing the bulk of the extract, without adding to its virtues. A convenient mode of performing this process, is to introduce the solid material into a vessel with an opening near the bottom temporarily closed, or into a funnel with its mouth loosely stopped, then to pour on the boiling water, and, having allowed it to remain a sufficient length of time, to draw it off through the opening. This operation may be repeated till the water comes away without any obvious impregnation. It is always desirable to obtain the solution in the first place as concentrated as possible, so as to prevent the necessity of long-continued evaporation, which injures the extract. It is better, therefore, to incur the risk, both when decoction and infusion are employed, of leaving a portion of the active matter behind, than to obtain a very weak solution. When successive portions of water are employed, those which are least impregnated should be brought by evaporation to the strength of that first obtained before being mixed with it, as the latter thus escapes unnecessary exposure to heat.

Sometimes the filtering of a turbid infusion or decoction, before evaporation, causes the resulting extract to keep better, by removing substances, which, besides undergoing decomposition themselves, may act as a ferment, and thus occasion the decomposition of the active matter of the extract.

When alcohol is employed as a menstruum, the vegetable should be macerated in it for one or two weeks, and care should be taken that the tincture be as nearly saturated as possible. The extraction may be hastened by substituting digestion for maceration; as the moderate heat employed, while it facilitates the action of the alcohol, has in this case no effect in promoting decomposition, and the influence of the atmospheric air may be excluded by performing the process in close vessels. When alcohol and water are both used, it is best, as a general rule, to exhaust the vegetable with each separately, as the two menstrua require different modes of treatment. In whichever of these modes the extraction is effected, it requires the assistance of occasional agitation; and, when the vegetable matter is very porous, and absorbs a large quantity of the solvent, expression must be resorted to.

Acetic acid has been introduced into use as a menstruum in the preparation of extracts. It is supposed to be a better solvent of the active principles of certain substances than either water or alcohol alone. According to Girolamo Ferrari, the acrid narcotics, such as aconite, hemlock, hyoscyamus, and stramonium, yield much stronger extracts with distilled vinegar than with water, and still stronger with alcohol to which strong acetic acid has been added. (*Journ de Pharm.*, 3*e sér.*, i. 239.) This acid is used in the preparation of the acetic extract of colchicum.

Ether also is now used to a considerable extent in the preparation of certain extracts. Having the property of dissolving volatile oil and resin, and of evaporating at a temperature insufficient to volatilize the oil, it is admirably adapted for the preparation of extracts from those substances, the virtues of which reside in the two principles referred to. An ethereal tincture is first prepared by the process of percolation or displacement, and the ether is then either allowed to escape by spontaneous evaporation, or is distilled off at a very moderate heat. The oleoresinous extracts thus obtained are usually of a thick fluid or semi-fluid consistence. For more precise information as to the mode of preparing them, the reader is referred to a paper by Prof. Procter, in the *Am. Journ. of Pharm.* (xxi. 114). Several of them are now ranked among the officinal preparations, in the U. S. Pharmacopœia, under the title of *Oleoresins*.

The process of percolation or displacement has within a few years been very advantageously applied to the preparation of extracts, both with water and spirituous menstrua. It has the following great advantages; 1. that it enables the soluble principles to be sufficiently extracted by cold water, thereby avoiding the injury resulting from heat in decoction and hot infusion; 2. that it effects the extraction much more quickly than can be done by maceration, thereby not only saving time, but also obviating the risk of spontaneous decomposition; and 3. that it affords the opportunity of obtaining highly concentrated solutions, thus diminishing the injurious effects of the subsequent evaporation. While thus advantageous, it is less liable in this particular case than in others to the objection of yielding imperfect results if not well performed; for, though an inexpert or careless operator may incur loss by an incomplete exhaustion of the substance acted on, and the extract may be deficient in quantity, it may still be of the intended strength and quality, which is not the case with infusions or tinctures unskilfully prepared upon this plan. In the U. S. Pharmacopœia, all the extracts to which the process is applicable are prepared by percolation, and, with a very few exceptions, without previous maceration or digestion, which, as a general rule, is useless if not injurious. In the British Pharmacopœia, the process is applied, as it were, hesitatingly to a portion of the extracts, and withheld in others to which it seems equally appropriate; and, as if there was an unwillingness to trust this exotic method entirely, previous maceration for a greater or less length of time, never less than twelve, and more generally for twenty-four hours, is with a single exception universally adopted, whenever percolation is employed. In this respect British pharmacy is, we think, behind that of the United States. For an account of the mode of operating in the process of displacement, and of the instruments used, the reader is referred to pages 894 and 905.

Some prefer the mode of expression to that of displacement. This also is applicable both to watery and alcoholic menstrua. The substance to be acted upon is mixed with the menstruum, cold or hot according to circumstances; and the mixture is allowed to stand from twelve to twenty-four hours. The liquid part is then filtered off, and the remainder submitted to strong pressure, in a linen bag, by means of a common screw press, or other convenient instrument. Another portion of the menstruum may then be added, and pressure again applied; and, if the substance is not sufficiently exhausted, the same operation may be performed a third time. Frequently only a single expression is required, and very

seldom a third. The quantity of menstruum added must vary with the solubility of the principles to be extracted. According to Mohr, the method of expression has the advantages over that of displacement, that it yields solutions of more uniform concentration, that it does not require the materials to be so carefully powdered, or otherwise so skilfully managed in order to ensure favourable results, and finally that it occupies less time.

2. *Mode of conducting the Evaporation.*

In evaporating the solutions obtained in the modes above described, attention should always be paid to the fact, that the extractive matter is constantly becoming insoluble at high temperatures with the access of air, and that other chemical changes are going on, sometimes not less injurious than this, while the volatile principles are expelled with the vapour. The operator should, therefore, observe two rules; 1. to conduct the evaporation at as low a temperature as is consistent with other objects; 2. to exclude atmospheric air as much as possible, and, when this cannot be accomplished, to expose the liquid the shortest possible time to its action. According to Berzelius, the injurious influence of atmospheric air is much greater at the boiling point of water than at a less heat, even allowing for the longer exposure in the latter case; and, therefore, a slow evaporation at a moderate heat is preferable to the more rapid effects of ebullition. Bearing these principles in mind, we shall proceed to examine the different modes in practice. First, however, it is proper to observe that decoctions generally let fall upon cooling a portion of insoluble matter; and it is a question whether this should be rejected, or retained so as to form a part of the extract. Though it is undoubtedly in many instances inert, as in that of the insoluble tannate of starch formed during the decoction of certain vegetable substances, yet, as it frequently also contains a portion of the active principle which a boiling saturated solution necessarily deposits on cooling, and, as it is difficult to decide with certainty when it is active and when otherwise, the safest plan, as a general rule, is to allow it to remain.

The method of evaporation usually resorted to in the case of aqueous solutions is rapid boiling over a fire. The more quickly the process is conducted the better, provided the liquid is to be brought to the boiling point; for the temperature cannot exceed this, and the length of exposure is diminished. But, even where this method is employed, it should not be continued till the completion of the evaporation; for, when most of the water has escaped, the temperature can no longer be kept down to the boiling point, and the extract is burnt. The caution, therefore, should always be observed of removing the preparation from the fire before it has attained the consistence of thick syrup, and completing the evaporation, either by means of a water-bath, or in shallow vessels at a moderate heat. When large quantities of liquid are to be evaporated, it is best to divide them into portions, and evaporate each separately; for, as each portion requires less time for evaporation than the whole, it will thus be a shorter time exposed to heat. (*Mohr.*) But the mode of evaporation by boiling is always more or less objectionable, and should be employed only in cases where the principles of the plant are so fixed and unchangeable as to authorize their extraction by decoction.

Evaporation by means of the water-bath, from the commencement of the process, is safer than the plan just mentioned, as it obviates all danger of burning the extract; but, as the heat is not supplied directly from the fire, the volatilization of the water cannot go on so rapidly, and the temperature being nearly the same, when the water-bath is kept boiling, there is greater risk of injurious action from the air. The liquid should be stirred during the process. The use of the vapour-bath, as suggested by M. Henry, is perhaps preferable; as it requires a smaller consumption of fuel, and the heat imparted to the liquid, while

sufficient to evaporate it, is less than 212°. We take the following description of the apparatus, employed at the Central Pharmacy of Paris, from M. Chevallier's highly useful Manual. It consists of a covered boiler, containing water, the vapour of which is conducted through a pipe into evaporating vessels, communicating with each other by means of metallic tubes. These vessels have the form of an ordinary copper basin, over the top of which is soldered a shallow tin capsule, intended to contain the liquor to be evaporated. The vapour from the boiler circulates through these vessels, and the water into which it condenses is allowed to escape through a stop-cock attached to the bottom of each vessel. From the last one of the series a tube passes into a vessel of water, so as to afford a slight pressure against the escape of any excess of vapour. The liquid to be evaporated is first distributed in two or three capsules, but, when considerably concentrated, is transferred to a single one, where it is stirred towards the close of the process to hasten the evaporation. The heat applied to the liquid, if there are four vessels, is in that nearest the boiler about 198° F., in the fourth or most remote, about 135°. An incidental advantage of this apparatus is, that it affords a large supply of distilled water.

As the heat capable of being applied by a boiling water-bath to the evaporating liquid does not exceed 200° F., while that by steam can, by a moderate pressure, be increased to the boiling point or beyond it, the evaporation by the latter agency may be much more rapid than by the former, according to Mr. Redwood, twice as rapid, when the pressure is from ten to twenty pounds to the square inch; so that there is a temptation to raise the heat to a degree seriously injurious to the product. Evaporation, therefore, by steam heat always requires caution, while the water-bath is much less liable to be abused. In this respect, the latter method has the advantage.

A good plan of evaporation, though slow, is to place the liquid in a broad, shallow vessel, exposed in a stove or drying room to a temperature of about 100°, or a little higher, taking care that the air have free access in order to facilitate the evaporation. This mode is particularly applicable to those cases in which maceration or infusion is preferred to decoction for extracting the active principles. Berzelius says that we may thus usually obtain the extract in the form of a yellowish transparent mass, while those prepared in the ordinary way are almost black, and are opaque even in very thin layers. Even when the liquid is boiled at first, the process may often be advantageously completed in this manner. It has been proposed to effect the evaporation at the common temperature, by directing a strong current of air, by means of a pair of smith's bellows, over the surface of the liquid; and, in reference to substances which are injured by heat and not by atmospheric air, the plan will be found useful.

Plans have been proposed and carried into execution for performing evaporation without the admission of atmospheric air. The apparatus for evaporation in vacuo, invented by Mr. Barry, and described in the *Lond. Journ. of Science and Arts* (vol. viii. p. 360), is well calculated to meet this object, at the same time that, by removing the atmospheric pressure, it enables the water to rise in vapour more rapidly, and at a comparatively low temperature. The method of Barry consists in distilling the liquid into a large receiver, from which the air has been expelled by steam, and in which the vapour is condensed by cold water applied to the surface of the receiver, so as to maintain a partial vacuum. Mr. Redwood has modified this process by keeping an air-pump in action during the evaporation, thus removing not only the air, but the vapour as fast as it forms, and maintaining a more complete vacuum than can be done by the condensation of the vapour alone. (*Journ. de Pharm.*, 3*e sér.*, i. 231.) Another method is to place the liquid under an exhausted receiver, together with some concentrated sulphuric acid or chloride of calcium, which, by its affinity for water, promotes the evaporation of the liquid. But, from the expense and trouble

of these modes of evaporation, they are not calculated for general use. Dr. Christison recommends as probably the most perfect and convenient method, especially with watery infusions and decoctions, to evaporate the fluid in a vacuum to the consistence of syrup, and then to complete the process in shallow vessels, exposed to a current of air without heat.*

A convenient plan of excluding the air, though it does not at the same time meet the object of reducing the requisite degree of heat, is to distil off the water in close vessels. Berzelius says that this is the best mode of concentration next to that *in vacuo*. Care, however, must be taken that the fire be not too long applied, lest the extract should be burnt. The process should, therefore, be completed by means of the water-bath.

In the concentration of alcoholic solutions, distillation should always be performed; as not only is the atmospheric air thus excluded, but the alcohol is recovered, if not absolutely pure, certainly fit for the purpose to which it was originally applied. Here also the water-bath should be employed, to obviate any possible risk of injury from the fire. When the decoction or infusion, and tincture of the same vegetable have been made separately, they should be separately evaporated to the consistence of syrup, and then mixed together, while they are of such a consistence as to incorporate without difficulty. The object of this separate evaporation is, that the spirituous extract may not be exposed to the degree of heat, or lengthened action of the air, which is necessary in the ordinary mode of concentrating the infusion or decoction.

In every instance, care should be taken to prevent any portion of the extract from becoming dry and hard on the sides of the evaporating vessel, as in this state it will not readily incorporate with the remaining mass. The heat, therefore, should be applied to the bottom, and not to the sides of the vessel.

3. *Condition and Preservation of Extracts.*

Extracts are prepared of two different degrees of consistence; soft so that they may be readily made into pills, and hard that they may be pulverized. In astringent extracts, the evaporation should be carried to dryness. Those obtained from the expressed juices of plants are apt to attract moisture from the air, in consequence of the deliquescent nature of the salts existing in the juice. They are thus rendered softer, and more liable to become mouldy upon the surface. Others, especially such as contain much chlorophyll, harden by time, in consequence of the escape of their moisture; and it not unfrequently happens that small crystals of saline matter are formed in their substance. Most extracts, especially those containing azotized principles, are capable, when left to themselves, of producing nitrates. Mr. John Attfield, of London, has made a chemical examination of the crystals found in numerous extracts, and ascertained that, in a large number, they consisted of chloride of potassium, and, in a com-

* M. Grandval has described an apparatus for evaporation in vacuo, for the preparation of extracts, in the *Journ. de Pharm.* (xv. 82). In the same journal (xxiii 1), MM. Soubeiran and Gobley have described and figured an apparatus, founded upon that of M. Grandval, but modified so as to be adapted to operations on a small scale, and to be within the reach of apothecaries who may desire to prepare their own extracts. Messrs. Tilden & Co., of New York, employ a vacuum apparatus analogous to that used in refining sugar. The vacuum is obtained and continued by the constant action of a powerful steam-driven pump. Their apparatus includes two evaporating pans; one large, having a capacity of several hundred gallons, used to concentrate the solutions for extracts to a syrupy consistence; the other, holding about fifty gallons, in which the evaporation is finished. The latter is furnished with an opening of such size as to permit the operator to remove the residual extract. The temperature during the evaporation is from 120° to 140° F., and is derived from steam pipes, placed within the boiler in the large evaporating pan, and a steam jacket beneath the smaller one. Very fine extracts are prepared in this way.—*Note to the ninth and tenth editions.*

paratively few, of the nitrate of potassa.* The air, moreover, exercises an unfavourable chemical influence over the softer extracts, which are enfeebled, and ultimately become nearly inert, by the same changes which they undergo more rapidly in the liquid state at an elevated temperature. If an extract be dissolved in water, and the liquid be saturated with common salt, or any other very soluble salt of difficult decomposition, the greater part of it will be precipitated, in consequence of the insolubility of this class of substances in saline solutions. The precipitate may be again dissolved in pure water.

Extracts, in order that they may keep well, should be placed in glazed earthenware, glass, or porcelain jars, and completely protected from the access of the air. This may be effected by covering their surface with a layer of melted wax, or with a piece of paper moistened with strong spirit, then closing the mouth of the vessel with a cork, spreading wax or rosin over this, and covering the whole with leather, or a piece of bladder. (*Duncan.*) The dry extracts, being less liable to be affected by atmospheric oxygen, do not require so much care. The application of alcohol to the surface has a tendency to prevent mouldiness. A method of protecting extracts from the action of the air, frequently resorted to, is to cover them closely with oiled bladder; but this, though better than to leave them uncovered, is not entirely effectual. Should the extract become too moist, it may be dried by means of a water-bath; should it, on the contrary, be too dry, the proper consistence may be restored by softening it in the same manner, and incorporating with it a little distilled water. (*Chevallier.*)

Some extracts when powdered have a tendency to cohere again. According to Geiseler, this may be obviated by the addition of sugar of milk or powdered liquorice-root; two or three parts of the former, and one part of the latter to one of the extract being sufficient for the purpose. (*Pharm. Cent. Blatt*, A. D. 1850, p. 238.) Mohr recommends the following plan of drying and preserving extracts. Take equal parts of powdered liquorice-root and of the extract, rub them well together in a mortar, put the resulting paste into an earthen vessel with a flat bottom, place this in another of iron, a little deeper, containing chloride of calcium thoroughly dried by heat insufficient to melt it; then enclose the whole with a cover fitted to the iron vessel, and allow them to stand for a day or more. When the mixture is quite dry, powder it, and add so much of the powdered root as to make the weight double that of the original extract. (*Ibid.*, p. 719.)

Extracts from recent plants should be prepared at the season when the plant is medicinally most active; and a good rule is to prepare them once a year.†

Mr. T. S. Wiegand considers glycerin as the best excipient for extracts given in the form of liquid mixture, or applied externally; equal parts being used in the former case, and a double proportion of glycerin in the latter. (*Am. Journ. of Pharm.*, March, 1863, p. 117.)

* Thus, chloride of potassium was detected in the extracts of belladonna, hemlock, sarsaparilla (compound), colchicum seeds, stramonium seeds, and aconite; nitrate of potassa in extracts of belladonna, hyoscyamus, and lettuce; and sulphate of soda in extract of stramonium seeds. (*Pharm. Journ.*, March, 1862, p. 448.)

† M. Lepage, of Gisors, gives the following method of testing the quality of the narcotic extracts, and determining whether they contain any of the alkaloids to which they owe their efficiency. Take a gramme (15·3 grs.) of the extract, dissolve it in twice its weight of distilled water, introduce the solution into a test-tube, and add from 25 to 30 centigrammes (4 or 5 grs.) of powdered bicarbonate of potassa. When effervescence has ceased, add to the mixture 5 or 6 times its bulk of pure ether, cork the tube, and shake briskly three times in 2 or 3 minutes. Then let the mixture rest; and, when the ether has become transparent, decant, and allow it to evaporate spontaneously. Dissolve the residue in 6 or 8 grammes (ʒiss. to ʒij.) of water, acidulated with a drop or two of muriatic acid. If the extract be good, the solution will be rendered very turbid by a few drops of a solution of the double iodide of mercury and potassium, and will give a flocculent precipitate with solution of tannic acid. (*Journ. de Pharm.*, Mai, 1863, p. 362.) This test is applicable to the extracts of aconite, belladonna, hyoscyamus, and conium.—*Note to the twelfth edition.*

4. *General Officinal Directions.*

"In preparing the Extracts, unless otherwise directed, evaporate as quickly as possible, in a broad, shallow vessel, by means of a water-bath, until they have acquired the consistence proper for forming pills; and, towards the end of the process, stir them constantly with a spatula. Sprinkle upon the softer Extracts a small quantity of Alcohol." *U. S.*

EXTRACTUM ACONITI. *Br. Extract of Aconite.*

"Take of the fresh Leaves and Flowering Tops of Aconite *one hundred and twelve pounds* [avoirdupois]. Bruise in a stone mortar, and press out the juice; heat it gradually to 130°, and separate the green colouring matter by a calico filter. Heat the strained liquor to 200° to coagulate the albumen, and again filter. Evaporate the filtrate by a water-bath to the consistence of a thin syrup; then add to it the green colouring matter previously separated, and, stirring the whole together assiduously, continue the evaporation at a temperature not exceeding 140°, until the extract is of a proper consistence." *Br.*

The extract from the fresh leaves of aconite has been abandoned in the U. S. Pharmacopœia, probably because the plant is not generally cultivated in this country. It will be perceived that, in the British process, not the leaves only, but the flowering tops also are used, as experience has shown that these are at least equally efficient. The process consists essentially in the evaporation of the expressed juice; and the product, therefore, ranks with inspissated juices.

In relation to the preparation of this extract, as well as of all others derived from the expressed juices of narcotic plants, the following summary of the plan pursued by Mr. Battley, an experienced apothecary of London, may be of service. Having passed the expressed juice through a fine hair sieve, he places it immediately upon the fire. Before it boils, a quantity of green matter rises to the surface, which in some plants is very abundant. This is removed by a perforated tin dish, and preserved. It ceases to appear soon after the liquid begins to boil. The boiling is continued till rather more than half the fluid has been evaporated, when the decoction is poured into a conical pan and allowed to cool. An abundant dark-green precipitate forms, from which the supernatant liquid is poured off; and this, having been reduced one-half by a second boiling, is again allowed to stand. The precipitate which now falls is less green than the first. The remaining fluid is once more placed over the fire, and allowed to boil till it assumes the consistence of syrup, when it is removed. The matter at first collected by skimming, together with that precipitated, is now incorporated with it, and the whole placed in a metallic pan, and by means of a water-bath evaporated to the consistence of an extract. In the latter part of the process, care is necessary to prevent the extract from hardening on the sides of the vessel, as it thus loses its fine green colour, and becomes proportionably feeble.

The superiority of this plan over a continuous boiling is, that the portions of active matter which are deposited at different stages of the process are subjected for a shorter time to heat than if allowed to remain in the liquor, and are consequently less deteriorated. The matter which coagulates before the fluid boils is chiefly albumen, embracing portions of chlorophyll and of the undissolved vegetable fibre. It might probably be thrown away without diminishing the virtues of the extract; but as chlorophyll, though itself inactive, has often associated with it a portion of the active principle, it is the most economical plan to incorporate it with the other matters, and, besides, its presence in the mass is said to render it easier to be worked into pills. Mr. Brande states that one cwt. of fresh aconite yields about five pounds of extract. According to Geiger, one pound yields an ounce and a half.

In the new process of the British Pharmacopœia, it will be perceived that a

discrimination is made between the chlorophyll and albumen; the former, which coagulates at 130°, being at first separated in order to prevent the continuous action of heat upon it, and afterwards added to the extract; the latter, coagulating at 200°, is separated and rejected. The rejection of the albumen is altogether advisable, as it is not only inert, but renders the extract more liable to decomposition. The chlorophyll is retained for the reasons stated in the preceding paragraph; and also to give a greenish colour to the extract, which has come to be associated in general opinion with its goodness of quality.

When properly prepared, this extract has a greenish-brown colour, with a disagreeable narcotic odour, and the acrid taste of the plant. It may be given in the dose of one or two grains, night and morning, to be gradually increased till the system is affected. Twenty grains or more have been given in the course of a day. W.

EXTRACTUM ACONITI ALCOHOLICUM. *U. S. Alcoholic Extract of Aconite.*

"Take of Aconite Leaf, recently dried and in fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Introduce the powder, previously mixed with one-third of the Alcohol, into a conical percolator, and pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour on Diluted Alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted Alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate, by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup, and add the three fluidounces of tincture first obtained. Lastly, continue the evaporation, at a temperature not exceeding 120°, until the whole is reduced to the proper consistence." *U. S.*

The exhaustion of the aconite in this process is indicated by the absence of its peculiar taste in the liquid which passes.

By the former U. S. process the alcohol in the evaporation was recovered by distillation and saved. In the present, this is impossible at the low temperature at which the evaporation is directed, unless by the aid of a vacuum apparatus; but, at the present high price of alcohol, it would be advisable for every apothecary, who prepares these alcoholic extracts, to be provided with such an instrument. The attempt to save the alcohol by ordinary distillation would imply an elevation of the heat above that officinally ordered, and thus endanger the decomposition of the active principle of the aconite; and views of economy should never be allowed to interfere with the efficiency of medicines.

If made from recently dried leaves, which have not yet been impaired by time, this is a good preparation of aconite; and it is believed to be more powerful, and to keep better, than the inspissated juice. According to Prof. Schroff, of Vienna, it has four times the strength of that preparation. The dose is half a grain or a grain, to be gradually increased if necessary.

An alcoholic extract prepared from the root is stronger, and may be given in the dose of one-sixth or one-quarter of a grain three times a day, to be gradually increased until its effects are experienced.* W.

* *Plaster of Aconite.* It is often desirable to employ aconite externally in the form of a plaster, and for this purpose the alcoholic extract of the root may be advantageously resorted to. Professor Procter prepares such a plaster by the following process. Mix four ounces of the coarsely powdered root with six fluidounces of alcohol (sp. gr. 0·835), macerate for 24 hours, then submit the mixture to percolation with alcohol, so as to obtain a pint of tincture. From this distil off three-fourths of the alcohol, and evaporate the residue by a water-bath to a syrupy consistence. While it is still hot, add three ounces and a half of adhesive plaster, previously melted, and stir the mixture constantly till it cools. About four ounces of plaster are thus obtained. (*Am. Journ. of Pharm.*, xxv. 202.) —*Note to the tenth edition.*

EXTRACTUM ALOES BARBADENSIS. *Br. Extract of Barbadoes Aloes.*

"Take of Barbadoes Aloes, in small fragments, *one pound* [avoirdupois]; Boiling Distilled Water *one gallon* [Imperial measure]. Add the Aloes to the Water, and stir well until they are thoroughly mixed. Set aside for twelve hours; then pour off the clear liquor, strain the remainder, and evaporate the mixed liquors by a water-bath or a current of warm air to a proper consistence." *Br.*

EXTRACTUM ALOES SOCOTRINÆ. *Br. Extract of Socotrine Aloes.*

This is prepared precisely as the Barbadoes Aloes.

The object of these processes is to separate from aloes the resinoid matter, the *apotheme* of Berzelius, which is supposed to irritate the bowels, without possessing purgative properties; but the truth appears to be, that, when deprived of a small proportion of adhering extractive, this matter is quite inert. It cannot, therefore, injuriously affect the virtues of the medicine; and, as it exists in comparatively small proportion, and during the process a part of the extractive becomes insoluble, the preparation may be considered as at best unnecessary. The dose of the purified aloes is from five to fifteen grains.*

Off. Prep. Decoctum Aloës Compositum, *Br.* W.

EXTRACTUM ANTHEMIDIS. *Br. Extract of Chamomile.*

"Take of Chamomile Flowers *one pound* [avoirdupois]; Oil of Chamomile *fifteen minims;* Distilled Water *a sufficient quantity.* Digest the Chamomile in six pints [Imperial measure] of the Water for twelve hours, pour off the clear liquor and press; again digest, and press as before. Evaporate the mixed liquors by a water-bath to a proper consistence, adding the Oil of Chamomile at the end of the process." *Br.*

According to Mr. Brande, one cwt. of dried chamomile flowers affords upon an average 48 pounds of extract.

This extract has a deep-brown colour, with the bitter taste and aroma of chamomile. It much better represents the chamomile than the old Edinburgh extract, which, being obtained by decoction and inspissation, contained none of the volatile oil of the plant. In the present British process, not only is care taken to avoid boiling, but also to supply any possible loss of oil during the cautious evaporation, by the addition of a small portion near the close of the process. The extract may be given for the same purposes as the flowers, but is most used as a vehicle for other tonics in the pilular form. The dose is from ten to twenty

* *Glycerate of Aloes. Glycerole of Aloes.* Under the latter name, M. Chausit brought to the notice of the profession a preparation consisting of an alcoholic extract of aloes dissolved in glycerin. Mr. Haselden prepared this in the following method. Macerating half an ounce of aloes in four fluidounces of alcohol until dissolved, he filtered the tincture through bibulous paper, evaporated it to the consistence of molasses, and, while it was still warm, added enough glycerin to make four fluidounces. Finding that the aloes was wholly dissolved, with the exception of a little impurity, he concluded that the spirit might very well be dispensed with, and the aloes used directly in the process. Accordingly, he proposes to substitute the following method. Mix well in a mortar half an ounce of Socotrine aloes, in fine powder, and four fluidounces of glycerin; transfer the mixture to a bottle, and agitate occasionally for several days; if the aloes be not now dissolved, heat for fifteen minutes by a water-bath, and strain through linen to separate impurities. The resulting liquid is of a bright mahogany colour, and of the consistence of glycerin. The preparation has been recommended as an external remedy in lichen agrius and the excoriations of eczema, applied by means of a camel's hair brush. (*Pharm. Journ.*, Dec. 1859, p. 322.) It is unfortunate, we think, that the French name of glycerole has been employed to express solutions in glycerin, as this has been adopted as the termination of certain proximate principles. It appears to us that the term *glycerate* would be unexceptionable: as it is sufficiently expressive, and no confusion could result. For the mode of preparing a *fluid extract of aloes* with the aid of glycerin, by Prof. Procter, see *Proceed. of Am. Pharm. Assoc.*, 1868, p. 240.—*Note to the twelfth edition.*

grains. An extract may be prepared, having the peculiar flavour as well as bitterness of chamomile, by macerating the flowers in water, and evaporating the infusion in vacuo. W.

EXTRACTUM ARNICÆ ALCOHOLICUM. *U. S.* *Alcoholic Extract of Arnica.*

"Take of Arnica, in moderately coarse powder, *twenty-four troyounces;* Alcohol *four pints;* Water *two pints;* Diluted Alcohol *a sufficient quantity.* Mix the Alcohol and Water, and moisten the powder with a pint of the mixture; then pack it firmly in a cylindrical percolator, and gradually pour on the remainder of the mixture. Continue the percolation with Diluted Alcohol until six pints of tincture have passed. Lastly, evaporate this, by means of a water-bath, to the proper consistence." *U. S.*

This extract very well represents the virtues of arnica, and is a convenient form for its administration. According to Prof. Procter, it amounts, in the soft state, to 33 per cent. of the flowers. The dose is from five to ten grains. But the chief employment of the extract is in the preparation of the plaster. (See *Emplastrum Arnicæ.*)

Off. Prep. Emplastrum Arnicæ, *U. S.* W.

EXTRACTUM BELLADONNÆ. *U. S.*, *Br.* *Extract of Belladonna.*

"Take of Belladonna Leaf, fresh, *twelve troyounces.* Bruise the Leaf in a stone mortar, sprinkling on it a little water, and express the juice; then, having heated this to the boiling point, strain, and evaporate to the proper consistence." *U. S.*

The British Pharmacopœia takes the "fresh leaves and young branches of Belladonna," and prepares the Extract from them in the same manner precisely as Extract of Aconite. (See *Extractum Aconiti.*)

The U. S. Pharmacopœia directs this extract to be prepared from the leaves of the plant, the British from the leaves and young branches. The latter direction was probably based on experiments by Mr. Squire, of London, who found that an extract prepared from the soft herbaceous parts of the plant generally, including leaves, flowers, and young stalks, not only has a better consistence, and is less apt to become mouldy by keeping, than that made from the leaves exclusively, but is more effectual in the same quantity. (*Pharm. Journ.*, Dec. 1861, p. 300.) There is little doubt of the accuracy of these results, and it is to be hoped that, in a future edition of our officinal standard, should they be confirmed by further observation, the same measure may be adopted. It is probable that these remarks are as applicable to other extracts prepared from fresh leaves as to that of belladonna, at least in relation to perennial plants.

From the experiments of MM. Solon and Soubeiran, it appears that, in relation to this extract, the insoluble matter separated from the expressed juice by filtering, and that coagulated by heat, are nearly if not quite inert; so that advantage results from clarifying the juice by these means before evaporating it. So far as the albumen is concerned, there can be no doubt of the accuracy of this statement; but it is questionable whether the same remark is applicable to the chlorophyll which first separates, and which is reserved in the British process. (See *Extractum Aconiti*, page 1085.) Mr. Brande states that one cwt. of fresh belladonna yields from 4 to 6 pounds of extract. According to M. Recluz, nearly ten parts may be obtained from one hundred. The best extract is brought chiefly from England; but Mr. Alfred Jones has found that it may be prepared of equally good quality from the plant grown in the United States. (*Am. Journ. of Pharm.*, xxiv. 108.) It has usually a dark-brown colour, a slightly narcotic not unpleasant odour, a bitterish taste, and a soft consistence which it long retains. Asparagin has been found in this extract. (*Journ. de Pharm.*, xxi. 178.)

Its medical properties and uses have been detailed under the head of Bella-

donna. A few words in relation to its mode of application may be proper here. For the dilatation of the pupil, it is either mixed with water to the consistence of cream and rubbed on the brow and eyelids, or dissolved in water and dropped into the eye. In rigidity of the os uteri, it is applied at intervals to the neck of the uterus, mixed with simple ointment in the proportion of two drachms to an ounce; but care must be taken not too powerfully to affect the system; and the preparation, therefore, should be used in a small quantity at first. In irritability of the bladder, chordee, spasm of the urethra, and painful constriction of the rectum, it may either be rubbed in the form of ointment upon the perineum, along the urethra, &c., or may be used in the form of enema; but care is requisite not to introduce it too freely into the bowel. It is sometimes smeared upon the bougie, mixed with oil, in the treatment of stricture of the urethra. In the form of ointment it has been beneficially employed in phymosis and paraphymosis, and in that of plaster or ointment, in local neuralgic or rheumatic pains. (See *Emplastrum Belladonnæ.*) The dose of the extract is uncertain on account of its variable strength. The best plan is to begin with one-quarter or one half of a grain, repeated two or three times a day, and gradually to increase the dose till the effects of the medicine are experienced. To a child two years old not more than one-twelfth of a grain should be administered at first.

Off. Prep. Emplastrum Belladonnæ, *Br.;* Unguentum Belladonnæ. W.

EXTRACTUM BELLADONNÆ ALCOHOLICUM. *U. S. Alcoholic Extract of Belladonna.*

"Take of Belladonna Leaf, in fine powder, *twenty-four troyounces;* Alcohol *four pints;* Water *two pints;* Diluted Alcohol *a sufficient quantity.* Mix the Alcohol and Water, and moisten the powder with a pint of the mixture; then pack it firmly in a conical percolator, and gradually pour upon it the remainder of the mixture. Continue the percolation with Diluted Alcohol until six pints of tincture have passed. Lastly, evaporate this, by means of a water-bath, to the proper consistence." *U. S.*

This is a good preparation, though less necessary than some other spirituous extracts of the narcotic plants; as the inspissated juice, or common extract of belladonna, can generally be procured of good quality. It is one of the officinals of the French Codex. The dose to begin with is half a grain.

Off. Prep. Emplastrum Belladonnæ, *U. S.* W.

EXTRACTUM CALUMBÆ. *Br. Extract of Columbo.*

"Take of Columbo, in powder, *one pound* [avoirdupois]; Proof Spirit *four pints* [Imperial measure]. Macerate the Columbo in two pints of the Spirit for twenty-four hours; pack in a percolator, and pass the remainder of the Spirit slowly through it; distil off the Spirit; and evaporate the residue to the proper consistence." *Br.*

As proof spirit takes up all the active matter of columbo, leaving the starch and albumen behind, the extract prepared according to this formula has, in a comparatively small bulk, all the powers of the root, except those of the small proportion of volatile oil which may be dissipated in the process. It may be given in the dose of from five to fifteen grains three times a day. W.

EXTRACTUM CANNABIS PURIFICATUM. *U. S.* EXTRACTUM CANNABIS INDICÆ. *Br. Purified Extract of Hemp. Extract of Indian Hemp.*

"Take of Extract of Hemp *two troyounces;* Alcohol *a sufficient quantity.* Rub the Extract with two fluidounces of Alcohol until they are thoroughly mixed; and, having added twelve fluidounces of Alcohol, allow the mixture to macerate for twenty-four hours. Then filter the tincture through paper, passing sufficient Alcohol, through the filter, to exhaust the dregs completely. Lastly,

by means of a water-bath, at a temperature not exceeding 160°, evaporate to dryness." *U. S.*

"Take of Indian Hemp, in coarse powder, *one pound* [avoirdupois]; Rectified Spirit *four pints* [Imperial measure]. Macerate the Hemp in the Spirit for seven days, and press out the tincture. Distil off the Spirit, and evaporate by a water-bath to a proper consistence." *Br.*

These are not identical preparations; the U. S. purified extract being made from the impure extract imported from India, the British extract from the dried plant. It is probable that the former would be found most efficient.

Prof. Procter has investigated the subject of the tests for purified extract or resin of hemp, and come to the following conclusions. Its peculiar odour when moderately heated, its indifference to alkalies, and its solubility in alcohol, ether, chloroform, benzole, and oil of turpentine are characteristic though not entirely distinctive properties. The best test, he thinks, is nitric acid (sp. gr. 1·38), which acts slowly when cold, but with heat rapidly, evolving red fumes, and converting the resin into an orange-red resinoid substance, which, when washed and dried, closely resembles gamboge in colour. (*Proceed. of the Am. Pharm. Assoc.*, A. D. 1864.)

For remarks in relation to the uses and doses of this preparation, see *Extractum Cannabis*, in Part I. (*page* 381). It is no doubt of more uniform strength than the crude extract, but cannot always be relied on as equable in this respect, and therefore should be prescribed with caution in relation to the dose.

Off. Prep. Tinctura Cannabis, *U. S.*; Tinctura Cannabis Indicæ, *Br.* W.

EXTRACTUM CINCHONÆ. *U. S. Extract of Cinchona.*

"Take of Yellow Cinchona, in fine powder, *twelve troyounces;* Alcohol *four pints;* Water *a sufficient quantity.* Introduce the powder, previously mixed with three fluidounces of Alcohol, into a conical glass percolator, and gradually pour upon it the remainder of the Alcohol. When the liquid ceases to pass, pour upon the residue sufficient Water to keep its surface covered, until four pints of tincture have passed. Set this aside, and continue the percolation until six pints of infusion are obtained. Distil off the alcohol from the tincture, and evaporate the infusion until the liquids respectively are brought to the consistence of thin honey; then mix them, and evaporate to the proper consistence." *U. S.*

The yellow or Calisaya bark is selected for this preparation, as it can always be relied on as efficient. By this process all the virtues of the bark are extracted; the parts soluble in alcohol being first taken up, and afterwards those in water, and the tincture and infusion thus obtained separately. This proceeding has the great advantage that no more heat is necessary to evaporate the tincture than the alcoholic menstruum requires; while, if the two liquids were mixed, it would be necessarily subjected to a longer continuance if not a higher degree of the heat; and the advantage is the greater as most of the active matter is extracted in the first percolation with alcohol. If proper care be taken in executing the process, both in relation to the percolation, and the avoidance of too high a temperature, the extract will fully represent the virtues of the bark.

The former extracts of cinchona of the British Colleges are all omitted in the new British Pharmacopœia, which directs in their place a fluid extract, under the name of *Extractum Cinchonæ Liquidum*, which will be treated of among the Fluid Extracts.

A very good extract of bark was formerly prepared, in the shops of Philadelphia, by macerating cinchona for a considerable length of time in a large proportion of water, and slowly evaporating the infusion, by a very moderate heat, in large shallow dishes placed upon the top of a stove. Before the use of sulphate of quinia had superseded that of most other preparations of bark, we employed this extract with success in the treatment of intermittents, and found ten grains of it equivalent to nearly a drachm of the powdered cinchona.

The extract should always be brought to the hard dry state in which it may be

pulverized; as it is thus less apt to be injured by exposure, and in the state of powder may be more uniformly incorporated with other substances. Though directed officinally to be prepared from the yellow or Calisaya bark, it would no doubt be equally efficient if made from the red.*

Medical Uses. The extract of Peruvian bark is at present much less employed than before the discovery of quinia. It is still, however, occasionally prescribed as a tonic in combination with other medicines; and, as it possesses, when properly prepared with a spirituous menstruum, almost all the active principles as they exist in the bark itself, it may be used in preference to the sulphate of quinia, whenever it is supposed that the latter is incapable of exerting all the curative influence of cinchona. We are told, however, that, on account of the high price of Calisaya bark, much of the extract as at present in the shops is prepared from inferior varieties. The dose is from ten to thirty grains, equivalent to about a drachm of the powdered bark. W.

EXTRACTUM COLCHICI. *Br. Extract of Colchicum.*

"Take of Fresh Colchicum Corms, deprived of their coats, *seven pounds* [avoirdupois]. Crush the Corms; press out the juice; allow the feculence to subside, and heat the clear liquor to 212°; then strain through flannel, and evaporate by a water-bath, at a temperature not exceeding 160°, to a proper consistence." *Br.*

There scarcely seems to be occasion for both this and the following extract. The dose is one or two grains.

In Great Britain a preparation called *preserved juice of colchicum* is given in the dose of five minims or more. It is made by expressing the fresh bulb, allowing the juice to stand for forty-eight hours that the feculent matter may subside, then adding one-quarter of its bulk of alcohol, allowing it again to stand for a short period, and ultimately filtering. W.

EXTRACTUM COLCHICI ACETICUM. *U. S., Br. Acetic Extract of Colchicum.*

"Take of Colchicum Root, in moderately fine powder, *twelve troyounces;* Acetic Acid *four fluidounces;* Water *a sufficient quantity.* To the Acetic Acid add a pint of Water, and mix the resulting liquid with the Colchicum Root. Transfer the mixture to a conical glass percolator, and pour Water gradually upon it until the liquid passes with little or no taste. Lastly, evaporate the liquid, in a porcelain vessel, to the proper consistence." *U. S.*

In the British Pharmacopœia this extract is directed to be prepared precisely as the preceding, except that *six fluidounces* of Acetic Acid (*Br.*) are to be added to the crushed corms before expression.

As the fresh colchicum bulb is rarely to be had in this country, the U. S. Pharmacopœia employs the dried bulb; and its process, if properly conducted, will afford a very efficient extract. Some inconveniences are experienced in preparing the extract, according to the London process, from the recent bulb by expression, which would seem to render the U. S. process under all circumstances preferable. (*Pharm. Journ.*, xiii. 62.)

The use of the acetic acid, in this preparation, is to render more soluble the alkaline principle upon which the virtues of meadow-saffron are thought to de-

* *Quinium.* Under this name a preparation has had some reputation in Europe, made by mixing quinia and cinchonia barks in such proportion that there should be about two parts of the former alkaloid to one of the latter, with half their weight of slaked lime, exhausting the mixture with alcohol, and then distilling and evaporating to dryness. The resulting *quinium* should yield one-third of its weight of the two alkaloids. The dose is three grains. The disadvantage of this as of all the amorphous preparations of the cinchona alkaloids, is the want of that protection against adulteration which is afforded by the crystalline form of the pure principles. (See *Am. Journ. of Pharm.*, Sept. 1858, p 400.)—*Note to the twelfth edition.*

pend. The acetic extract of colchicum is highly commended by Sir C. Scudamore, who prefers it made by evaporating, to the consistence of honey, a saturated acetic infusion of the dried bulb. (*Lond. Med. Gazette*, Dec. 10, 1841.) The dose of the extract is one or two grains, to be repeated two or three times a day, and increased if necessary. W.

EXTRACTUM COLOCYNTHIDIS ALCOHOLICUM. *U. S.* *Alcoholic Extract of Colocynth.*

"Take of Colocynth *forty-eight troyounces;* Diluted Alcohol *a sufficient quantity.* Dry the Colocynth, and, having removed the seeds, and reduced it to coarse powder by grinding or bruising, macerate it in eight pints of Diluted Alcohol for four days, with occasional stirring; then express strongly, and strain through flannel. Pack the residue, previously broken up with the hands, firmly in a cylindrical percolator, cover it with the strainer, and pour Diluted Alcohol upon it, until the tincture and expressed liquid, taken together, measure sixteen pints. Mix the tincture with the expressed liquid, and, having recovered from the mixture ten pints of alcohol by distillation, evaporate the residue to dryness by means of a water-bath. Lastly, reduce the dry mass to powder, and keep it in a well-stopped bottle. The Extract obtained by this process weighs about seven troyounces." *U. S.*

Colocynth should be deprived of its seeds, as directed by the U. S. Pharmacopœia, before being submitted to the action of the menstruum. Dr. Duncan found half a pound of colocynth to contain 2770 grains of seeds, which, boiled by themselves, yielded almost nothing to water. Dr. Squibb found selected fruits to yield from 25·8 to 34 per cent. of medullary part; and this, when well exhausted by diluted alcohol, to yield 60·7 to 60·8 per cent. of dry extract; while from the whole fruit, including pulp and seeds, from 15·69 to 20·6 per cent. was obtained according to the degree of dryness. (*Am. Journ. of Pharm.*, Jan. 1857, p. 98.) Boiling water extracts so much pectic acid and mucilage from colocynth, that the decoction or hot infusion gelatinizes on cooling; and the extract made by means of it is loaded with inert matter, and, besides, is apt to become mouldy, or so tough and hard as to resist trituration and formation into pills. Hence the London College, following in this respect the French Codex, directed, in the last edition of its Pharmacopœia, maceration with cold water; but diluted alcohol has been found to be a much better menstruum, and has been adopted in the U. S. process; while, in the British Pharmacopœia, the simple extract has been discarded altogether. The chief, if not exclusive use of the alcoholic extract is in the preparation of the compound extract.

Off. Prep. Extractum Colocynthidis Compositum, *U. S.* W.

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. *U. S.*, *Br.* *Compound Extract of Colocynth.*

"Take of Alcoholic Extract of Colocynth, in fine powder, *three troyounces and a half;* Socotrine Aloes, in fine powder, *twelve troyounces;* Resin of Scammony, in fine powder, *three troyounces;* Cardamom, in fine powder, *a troyounce;* Soap, in fine powder, *three troyounces.* Mix the powders thoroughly, and keep the mixture in a well-stopped bottle." *U. S.*

"Take of Colocynth, freed from the seeds, *six ounces;* Extract of Socotrine Aloes *twelve ounces;* Scammony or Resin of Scammony, in powder, *four ounces;* Hard Soap, in powder, *three ounces;* Cardamoms, freed from their capsules, in fine powder, *one ounce;* Proof Spirit *one gallon* [Imperial measure]. Macerate the Colocynth in the Spirit for four days; press out the tincture, and add to it the Extract of Aloes, the Soap, and the Scammony. Distil off the spirit, and evaporate the residue by a water-bath to a pilular consistence, adding the Cardamoms towards the end of the process." *Br.* The ounce employed in this process is the avoirdupois.

The present U. S. formula differs from that of 1850, in taking the alcoholic extract of colocynth already prepared, instead of directing its preparation from the colocynth, and in substituting resin of scammony for the scammony itself. The former provision ensures uniformity of result so far as the colocynth is concerned; whereas, by the old formula, this was impossible, owing to the variable quality of the colocynth employed, unless an unusual amount of care was taken in its selection. The second change contributes to the same result of uniformity; because the resin of scammony is very nearly of equable strength, while scammony is notoriously otherwise; and it has the additional advantage of yielding a stronger extract, as the resin is much more energetic in an equal dose than the crude drug as ordinarily found in the market. The object of the soap in this formula is to improve the consistence of the mass, which, when hardened by time, it renders more soluble in the liquors of the stomach. It may possibly also serve the purpose of qualifying the action of the aloes. In the U. S. process the extract is in the form of powder, which is very convenient for admixture with other substances; while, if given uncombined, it may be readily made into pills by suitable additions. The alternative of using the scammony or its resin, in the British formula, appears to us very objectionable.

This extract is an energetic and safe cathartic, possessing the activity of its three purgative ingredients, with comparatively little of the drastic character of the colocynth and scammony. It may be still further and advantageously modified by combination with rhubarb, jalap, calomel, &c., with one or more of which it is often united in prescription. In such combination it is much employed whenever an active cathartic is desirable, particularly in the commencement of fevers and febrile complaints, in congestion of the liver or portal system, and in obstinate constipation. In small doses it is an excellent laxative in that state of habitual costiveness, depending on a want of the due irritability of the bowels, which often occurs in old people. The dose is from five to thirty grains, according to the effect to be produced, and the susceptibility of the bowels. A very eligible combination is the compound cathartic pill of the U. S. Pharmacopœia. We are informed that much of the extract sold in this country is made with inferior scammony and aloes, and an insufficient proportion of colocynth, so that it is comparatively inert. Cheap compound extract of colocynth should be looked on with suspicion, and the apothecary should prepare it for himself.*

Off. Prep. Pilulæ Catharticæ Compositæ, *U. S.* W.

EXTRACTUM CONII. *U. S., Br. Extract of Hemlock.*

"Take of Hemlock, fresh, *twelve troyounces.* Bruise the Hemlock in a stone mortar, sprinkling on it a little water, and express the juice, then, having heated this to the boiling point, filter it, and evaporate to the proper consistence, either in a vacuum with the aid of heat, or in shallow vessels, at the ordinary temperature, by means of a current of air, directed over the surface of the liquid." *U. S.*

The directions of the *British Pharmacopœia* for this extract are precisely the same as those for the extract of aconite, the fresh leaves and young branches of conium being used.

The most important point in the preparation of this extract is to evaporate the juice without an undue degree of heat. At a temperature of 212° or upwards, its active principle undergoes rapid decomposition, being converted into resinous matter and ammonia. This is detected by the operator by the ammoniacal odour mixed with that which is peculiar to the plant. The juice always to a certain extent undergoes this decomposition when evaporated over a fire, and is not exempt from it even when the heat is regulated by a water-bath. Hence the pro-

* See in the *American Journal of Pharmacy* for March, 1857 (xxix. 97), and in the *Proceedings of the Am. Pharm. Assoc.*, 1858 (p. 411), some useful practical observations by Dr. E. R. Squibb, upon the best method of preparing this extract, so as to secure uniformity and efficiency.

priety of the directions in the U. S. and British Pharmacopœias. An excellent plan in the evaporation is to conduct it first in a vacuum, and afterwards in shallow vessels with a current of air at common temperatures. By the direction to heat the juice to the boiling point, or 200° (*Br.*), and then to filter, whereby the inert albumen is coagulated, and, with the equally inert chlorophyll and vegetable fibre, is separated from the liquid before evaporation, the extract is procured in a more concentrated state, and, besides, deprived of substances which might favour its decomposition. Long-continued exposure to the air is productive of the same result as too much heat, so that old extracts are frequently destitute of activity. (*Journ. de Pharm.*, xxii. 416.) No one of the extracts is more variable in its qualities than this. The season at which the herb is collected, the place and circumstances of its growth, the method of preparing the extract, are all points of importance, and are all too frequently neglected. (See *Conii Folia.*) In this country the process has often been carelessly conducted; and large quantities of an extract, prepared by boiling the plant in water and evaporating the decoction, have been sold as the genuine drug. The apothecary should always prepare the extract himself, or procure it from persons in whom he can have confidence. That imported from London has usually been considered the best; but we have seen and tried the extract prepared by the Messrs. Tilden & Co., of New York, by evaporation in vacuo at a low heat, and have found it superior to any that we had previously employed. It is not improbable that, as suggested to us by Professor Procter, the addition of a portion of acetic acid to the juice, before evaporation, might tend to fix the conia, and enable it better to resist the influence of heat than in its native combination. The activity of any specimen of the extract may be in some measure judged of by rubbing it with potassa, which, disengaging the *conia* and rendering it volatile, gives rise to the peculiar mouse-like odour of that principle. If no odour be evolved under these circumstances, the extract may be deemed inert.

The extract of hemlock prepared without separating the chlorophyll has a fresh olive or green colour, but, according to the U. S. process, is brownish. It should have a strong narcotic, somewhat fetid odour, and a bitterish saline taste. According to Brande, from three to five pounds are obtained from one cwt. of the leaves. M. Recluz got rather more than an ounce from sixteen ounces. Of the medical properties and application of this extract, we have spoken under the head of Conii Folia. The dose is two grains two, three, or four times a day, to be gradually increased till evidences of its action upon the system are afforded. It may be administered in pill or solution. W.

EXTRACTUM CONII ALCOHOLICUM. *U. S. Alcoholic Extract of Hemlock.*

"Take of Hemlock, recently dried and in fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Introduce the powder, previously mixed with one-third of the Alcohol, into a conical percolator, and pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour Diluted Alcohol upon it until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted Alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate this liquid, by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup. To this add the three fluidounces of tincture first obtained, and continue the evaporation, at a temperature not exceeding 120°, until the whole is reduced to the proper consistence." *U. S.*

This is one of the French officinal extracts, and, when well made from recently and carefully dried leaves, is a good preparation. The same caution is requisite in evaporating in this case as in that of the inspissated juice or common extract.

It will be noticed that care is taken in the formula to prevent injury from too great a heat, by first passing alcohol, which forms a highly concentrated tincture, and allowing this to evaporate spontaneously to three fluidounces, which is not added to the remainder until but little of the menstruum remains; and the process is completed at the low heat of 120°. This caution is necessary from the great facility with which conia is decomposed by heat. The proportion of extract yielded by dried hemlock, by percolation with alcohol, is, according to Messrs. Vielguth and Nentwich, 21·3 per cent. (See *Am. Journ. of Pharm.*, May, 1859, p. 237.) The dose, to begin with, is one or two grains, to be increased if necessary. W.

EXTRACTUM DIGITALIS ALCOHOLICUM. *U. S. Alcoholic Extract of Digitalis.*

"Take of Digitalis, recently dried and in fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Introduce the powder, previously mixed with one-third of the Alcohol, into a percolator, and pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour Diluted Alcohol upon it until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted Alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate this liquid, by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup. To this add the three fluidounces of tincture first obtained, and continue the evaporation, at a temperature not exceeding 120°, until the whole is reduced to the proper consistence." *U. S.*

This is a new officinal of the U. S. Pharmacopœia, though less needed than many others, because the dose of digitalis itself is small; and nothing is gained on the point of equability of strength; as the really active part of digitalis constitutes but a small proportion even of the extract, and might be altogether wanting without observably affecting its bulk. The same caution is used, in preparing this extract, against the injurious effects of heat as in the instance of the extract of conium. The skill, exhibited by the revisers of the Pharmacopœia in the application of the process of percolation to pharmaceutical purposes, is evinced nowhere more strongly than in the directions for preparing the extracts, fluid extracts, and oleoresins. The alcoholic extract of digitalis contains all the virtues and may be used for all the purposes of the powdered leaves. According to Messrs. Vielguth and Nentwich, the amount of alcoholic extract obtained from dried digitalis by cold displacement is 27·1 per cent. (See *Am. Journ. of Pharm.*, May, 1859, p. 237.) The dose, therefore, of this extract to begin with should not exceed one-fourth of a grain. W.

EXTRACTUM DULCAMARÆ. *U. S. Extract of Bittersweet.*

"Take of Bittersweet, in moderately fine powder, *twelve troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Bittersweet with four fluidounces of Diluted Alcohol, pack it in a conical percolator, and pour Diluted Alcohol gradually upon it until the tincture passes but slightly impregnated with the properties of the Bittersweet. Distil off the alcohol from the tincture until reduced to one-half; then strain, and, by means of a water-bath, evaporate to the proper consistence." *U. S.*

This preparation is well known on the continent of Europe, but comparatively little used in the United States or Great Britain. The substitution, in the late revision of the Pharmacopœia, of diluted alcohol for water as the menstruum is a decided improvement. The dose is from five to ten grains; but much more may be given with safety. W.

EXTRACTUM GENTIANÆ. *U. S., Br. Extract of Gentian.*

"Take of Gentian, in moderately coarse powder, *twelve troyounces;* Water

a sufficient quantity. Moisten the Gentian with four fluidounces of Water, pack it in a conical percolator, and gradually pour Water upon it until the infusion passes but slightly impregnated with the properties of the Gentian. Boil the liquid to three-fourths of its bulk; then strain, and, by means of a water-bath, evaporate to the proper consistence." *U. S.*

"Take of Gentian, sliced, *one pound* [avoirdupois]; Boiling Distilled Water *one gallon* [Imperial measure]. Macerate the Gentian in the Water for two hours, boil for fifteen minutes; pour off, press, and strain. Then evaporate by a water-bath to a proper consistence." *Br.*

The U. S. plan of percolation with cold water is admirably adapted to the extraction of the active matter of gentian, and even the British method of maceration with hot water is much better than the old method of decoction. By the use of cold water starch and pectic acid are left behind, while any albumen that may be taken up is got rid of by the boiling and straining.

The extract, however, may be advantageously made by macerating the root in two parts of water for thirty-six hours, then expressing in a powerful press, again macerating with additional water, and in like manner expressing, and evaporating the united expressed liquors. MM. Guibourt and Cadet de Vaux obtained by maceration in cold water an extract not only greater in amount, but more transparent, more bitter, and possessing more of the colour and smell of the root than that prepared by decoction. Guibourt attributes this result to the circumstance that, as gentian contains little if any starch, it yields nothing to boiling which it will not also yield to cold water; while decoction favours the combination of a portion of the colouring matter with the lignin. But this opinion requires modification, now that it is understood that gentian contains pectic acid, which water will extract when boiling hot, but not when cold. For observations in relation to the best modes of evaporation in the formation of extracts, the reader is referred to page 1082. Gentian, according to Brande, yields half its weight of extract by decoction.

As ordinarily procured, the extract of gentian is nearly inodorous, very bitter, of a dark-brown colour approaching to black, shining, and tenacious. It is frequently used as a tonic, in the form of pill, either alone or in connection with metallic preparations. The dose is from ten to thirty grains. W.

EXTRACTUM HÆMATOXYLI. *U. S.*, *Br.* *Extract of Logwood.*

"Take of Logwood, rasped, *twelve troyounces;* Water *eight pints.* Boil down to four pints, and strain the decoction while hot; then evaporate to dryness." *U. S.*

"Take of Logwood, in fine chips, *one pound* [avoirdupois]; Boiling Distilled Water *one gallon* [Imperial measure]. Macerate for twenty-four hours, then boil down to one-half, strain, and evaporate by a water-bath to a proper consistence, stirring with a wooden spatula." *Br.*

This is one of the few instances in which decoction in the preparation of extracts is not considered objectionable. Iron vessels should not be employed in the process, in consequence of the presence of tannic acid. The evaporation should be carried so far that the extract may be dry and brittle when cold. About 20 lbs. of it are obtained from one cwt. of logwood. (*Brande.*) It is of a deep-ruby colour, and an astringent, sweetish taste, and has all the medical virtues of the wood. If given in pills, these should be recently made, as, when long kept, they are said to become so hard as sometimes to pass unchanged through the bowels. The extract, however, is best administered in solution. The dose is from ten to thirty grains. This extract is said to be prepared largely in Yucatan and other parts of Mexico. W.

EXTRACTUM HELLEBORI ALCOHOLICUM. *U. S.* Extractum

HELLEBORI. *U. S.* 1850. *Alcoholic Extract of Black Hellebore. Extract of Hellebore.*

"Take of Black Hellebore, recently dried and in fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Introduce the powder, previously mixed with one-third of the Alcohol, into a conical percolator, and pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour on Diluted Alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted Alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate, by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup. To this add the three fluidounces of tincture first obtained, and continue the evaporation, at a temperature not exceeding 120°, until the whole is reduced to the proper consistence." *U. S.*

In consequence, probably, of the injurious influence of heat upon black hellebore, the watery extract prepared by decoction is little if at all stronger than the root. The process of percolation with cold spirit was, therefore, adopted in the U. S. Pharmacopœia of 1850, and has been retained with improvement in the present edition; and, if proper care be taken to conduct the evaporation at as low a temperature, and with as little exposure to the air as possible, an efficient extract will be obtained. Any resin which may be deposited during the evaporation should be separated from the sides of the vessel, and mixed with the rest. If the hellebore itself be of good quality, the extract will operate as a drastic purge in the dose of from five to ten grains.

The former French Codex contained a process for preparing the extract of hellebore, according to the method of Bacher. Two pounds of the root and half a pound of carbonate of potassa are digested, with a moderate heat, for twelve hours, in eight pounds of alcohol of 22° B.; the tincture is strained with expression; the residuum is again digested with eight pounds of white wine for twenty-four hours; the wine is expressed, and, having stood four hours to settle, is decanted; the liquors are then mixed, and with a gentle heat evaporated to the consistence of an extract. One ounce of this extract, mixed with the same quantity of myrrh, and with ten scruples of the powdered leaves of Centaurea benedicta, and made into pills of one grain each, constitutes the preparation known as the *tonic pills of Bacher*, formerly much used in amenorrhœa and dropsy, and probably not without advantage, especially in the former of these diseases. The dose is from ten to twenty pills during the day. An additional quantity of diluted alcohol might, without disadvantage, be substituted for the wine in the preparation of this extract. W.

EXTRACTUM HYOSCYAMI. *U. S., Br. Extract of Henbane.*

"Take of Henbane Leaf, fresh, *twelve troyounces.* Bruise the Leaf in a stone mortar, sprinkling on it a little water, and express the juice; then, having heated this to the boiling point, strain, and evaporate to the proper consistence." *U. S.*

In the British Pharmacopœia this extract is prepared from "the fresh Leaves and young Branches of Hyoscyamus" in the same manner precisely as Extract of Aconite. (See *Extractum Aconiti.*)

MM. Solon and Soubeiran have shown that the insoluble matter separated from the expressed juice of henbane by filtering, and that coagulated by heat, are nearly if not quite inert; so that the juice may be usefully clarified before evaporation. (*Amer. Journ. of Pharm.*, viii. 228.) The retention of the chlorophyll, however, as provided for in the British formula, is thought to be advantageous. Extract of Henbane has been chiefly derived from England, but it is at present prepared by Messrs. Tilden & Co., of New York, by the vacuum process. Mr. Brande says that one cwt. of the fresh herb affords between four and five pounds. M. Recluz obtained about one part from sixteen.

The extract is of a dark-olive colour, of a narcotic rather unpleasant odour, and a bitterish, nauseous, slightly saline taste. It retains its softness for a long time; but at the end of three or four years becomes dry, and exhibits, when broken, small crystals of nitrate of potassa and chloride of sodium. (*Recluz.*) Like all the inspissated juices it is of variable strength, according to its age, the care used in its preparation, and the character of the leaves from which it was procured. (See *Hyoscyamus.*)* In its use, therefore, it is advisable to begin with a moderate dose, two or three grains for instance, and gradually to increase the quantity till some effect is experienced, and the degree of efficiency of the particular parcel employed is ascertained. It is usually given in pill. It is sometimes used externally for the same purposes as extract of belladonna.

Off. Prep. Pilula Colocynthidis et Hyoscyami, *Br.* W.

EXTRACTUM HYOSCYAMI ALCOHOLICUM. *U. S.* *Alcoholic Extract of Henbane.*

"Take of Henbane Leaf, recently dried and in moderately fine powder, *twenty-four troyounces;* Alcohol *four pints;* Water *two pints;* Diluted Alcohol *a sufficient quantity.* Mix the Alcohol and Water, and moisten the powder with a pint of the mixture; then pack it firmly in a conical percolator, and gradually pour upon it the remainder of the mixture. Continue the percolation with Diluted Alcohol until the tincture measures six pints. Lastly, evaporate this, by means of a water-bath, to the proper consistence." *U. S.*

The alcoholic extract of henbane, if prepared from recently dried leaves, is thought to be more uniform and powerful than the inspissated juice or common extract. It is one of the preparations of the French Codex. The dose is one or two grains, to be gradually increased until its effects are obtained. W.

EXTRACTUM IGNATIÆ ALCOHOLICUM. *U. S.* *Alcoholic Extract of Ignatia.*

"Take of Ignatia, in fine powder, *twelve troyounces;* Alcohol *a sufficient quantity.* Mix the Ignatia with four fluidounces of Alcohol, and allow the mixture to stand for an hour. Then introduce it into a cylindrical percolator, press it firmly, and gradually pour Alcohol upon it until three pints of tincture have slowly passed. Distil off the Alcohol, by means of a water-bath, until the tincture is reduced to half a pint, and evaporate this to the proper consistence." *U. S.*

This was newly introduced into the present edition of the U. S. Pharmacopœia, not so much because the preparation is needed; for it is essentially the same in remedial properties and applications as the extract of nux vomica; as in order to give due officinal sanction to a preparation already in popular use, and, by

* Much depends on the choice of the leaves; and too little attention is paid to this point. In reference to the biennial plant, there seems to be no doubt that the leaves of the second year are much more efficacious than those of the first, and should, therefore, always be selected. It is stated under Hyoscyamus, in the first part of this work, that the leaves should be gathered soon after the plant has flowered. Mr. Charles Cracknell gives more particular directions. He thinks that the plant is in a fit state for collection only during a very short period; when the flowers at the top are blown, but have not yet begun to fade, and the seed-vessels and seeds which have been formed are still soft and juicy. For other observations on the preparation of this extract, see a paper by Mr. Cracknell in the *Am. Journ. of Pharm.* (xxiii. 245), from the *Pharm. Journ.*, March, 1851.

An important contribution to our knowledge, as to the proper choice of the parts of this plant to be expressed, has been made by Mr. T. B. Groves, of England. Whatever may be the case with those plants, such as aconite, the roots of which are active, and in which the juice, containing the active matter, on its way from the leaves to the root, might be supposed to exist in the young stems, this does not appear to be the case with the Hyoscyamus; and, accordingly, an extract obtained by inspissating the juice of the stems was found altogether inferior to another obtained in like manner from the leaves, being not only less in amount, but less bitter and odorous, and more saline, showing that it contained more of the ordinary salts of the plant, and less of its active matter. (*Pharm. Journ.*, Jan. 1862, p. 376.)

regulating it duly, to prevent serious consequences from so powerful a medicine.* For the uses of the extract the reader is referred to the article on Ignatia in *Part I.* The dose is from half a grain to three times that quantity, to be repeated three times a day until its effects begin to be experienced. W.

EXTRACTUM JALAPÆ. *U. S.*, *Br.* *Extract of Jalap.*

"Take of Jalap, in moderately fine powder, *twelve troyounces;* Alcohol *four pints;* Water *a sufficient quantity.* Introduce the powder, previously mixed with three fluidounces of Alcohol, into a conical percolator, and gradually pour upon it the remainder of the Alcohol. When the liquid ceases to pass, pour upon the residue sufficient water to keep its surface covered, until four pints of tincture have passed. Set this aside, and continue the percolation until six pints of infusion have been obtained. Distil off the alcohol from the tincture, and evaporate the infusion until the liquids respectively have been brought to the consistence of thin honey; then mix them, and evaporate to the proper consistence." *U. S.*

"Take of Jalap, in coarse powder, *one pound* [avoirdupois]; Rectified Spirit *four pints* [Imperial measure]; Distilled Water *one gallon* [Imp. meas.]. Macerate the Jalap in the Spirit for seven days; press out the tincture, then filter, and distil off the Spirit, leaving a soft extract. Again macerate the residual Jalap in Water for four hours, express, strain through flannel, and evaporate by a water-bath to a soft extract. Mix the two extracts, and evaporate, at a temperature not exceeding 140°, to a proper consistence." *Br.*

Jalap contains a considerable quantity of starch, which is extracted by decoction, but left behind by cold water; and, as this principle serves only to impede the filtration or straining, and augment the bulk of the extract, without adding to its virtues, cold water is very properly used in both the *U. S.* and *Br.* processes. The use both of alcohol and water has been deemed necessary, in order to extract all the medicinal qualities of the drug; and they are employed successively, under the impression that the previous removal of the resin by the former facilitates the action of the latter. The use of percolation, as directed by the U. S. Pharmacopœia, enables the cold water to extract the soluble parts without the long maceration which would otherwise be necessary. According to Cadet de Gassicourt, water at ordinary temperatures, and in the old mode, acts so slowly, that fermentation takes place before the active matter is all dissolved. Hence, if the extract be prepared without percolation, the residuum, after the tincture has been decanted, should be digested with water at a heat of about 90° or 100 F., which, while it is insufficient for the solution of the starch, enables the solvent to take up the active matter with sufficient rapidity.

One cwt. of jalap affords, according to Mr. Brande, about fifty pounds of aqueous extract and fifteen of resin. The product of the former is somewhat less by infusion than decoction; and the extract is proportionably stronger.

There is reason to believe, as we have been informed on good authority, that what is sold for extract of jalap is sometimes prepared from tubers which had been previously exhausted of their resin by alcohol; and a spurious substance has been offered in considerable quantities in our markets for extract of jalap, which, on examination by Messrs. Ch. Bullock and Ed. Parrish, proved to owe its purgative property to 42 per cent. of gamboge. (*Am. Journ. of Pharm.*, March, 1862, p. 113.)

Extract of jalap is of a dark-brown colour, slightly translucent at the edges, and tenacious when not perfectly dry. It contains the resin and gummy extrac-

* According to Prof. Procter, a portion of fixed oil is extracted by the alcohol, which separates when the concentrated tincture is allowed to stand, and, being in itself inert, might be rejected with advantage, care being taken to wash it first with alcohol, and add the washings to the liquid. The same result does not happen when diluted alcohol is used as the menstruum; as this does not take up the oil.

tive, and, consequently, has all the medical properties of the root; but it is not often exhibited alone, being chiefly used as an ingredient of purgative pills, for which it is adapted by its comparatively small bulk. It is most conveniently kept for use in the form of powder, which, however, is apt to attract moisture and to aggregate into a solid mass, unless carefully excluded from the air. The dose is from ten to twenty grains, or rather more than half that of jalap.*

Off. Prep. Pilulæ Catharticæ Compositæ, *U. S.* W.

EXTRACTUM JUGLANDIS. *U. S.* *Extract of Butternut.*

"Take of Butternut, in moderately coarse powder, *twelve troyounces;* Water *a sufficient quantity.* Moisten the Butternut with four fluidounces of Water, pack it in a conical percolator, and gradually pour Water upon it until the infusion passes but slightly impregnated with the properties of the Butternut. Boil the liquid to three-fourths of its bulk; then strain, and, by means of a water-bath, evaporate to the proper consistence." *U. S.*

This extract was formerly for the most part prepared by the country people, who are said to have used the bark of the branches and even the branches themselves, instead of the inner bark of the root; and to have injured the preparation by too much heat. That it should have proved uncertain in the hands of many physicians is, therefore, not a matter of surprise. It should be prepared by the apothecary, and from the inner bark of the root gathered in May or June. Experiments are yet wanting to prove that water is the best solvent of the active principles of this bark. Prof. Procter informs us that he has found an extract of the fresh bark prepared with diluted alcohol to have much more of the pungency of the bark than the officinal.

The extract of butternut is of a black colour, sweetish odour, and bitter astringent taste. In the dose of twenty or thirty grains, it acts as a mild cathartic. (See *Juglans.*) W.

EXTRACTUM KRAMERIÆ. *U. S.*, *Br.* *Extract of Rhatany.*

"Take of Rhatany, in moderately fine powder, *twelve troyounces;* Water *a sufficient quantity.* Moisten the powder with four fluidounces of Water, pack it in a conical percolator, and gradually pour Water upon it until the infusion passes but slightly impregnated with the astringent property of the Rhatany. Heat the liquid to the boiling point, strain, and, by means of a water-bath, at a temperature not exceeding 160°, evaporate to the proper consistence." *U. S.*

"Take of Rhatany, in coarse powder, *one pound* [avoirdupois]; Distilled Water *one gallon* [Imperial measure]. Macerate the Rhatany in a pint and a half [Imp. meas.] of the Water for twenty-four hours; then pack in a percolator, and add more Distilled Water, until twelve pints [Imp. meas.] have been collected, or the Rhatany is exhausted. Evaporate the liquor by a water-bath to a proper consistence." *Br.*

In selecting a plan for the preparation of this extract, it was undoubtedly wise to adopt the mode of displacement, with cold water as the menstruum. (See *page* 502.) It is absolutely necessary to the success of the process, that the root should be well and uniformly comminuted; and the "moderately fine powder" of the U. S. Pharmacopœia is, therefore, preferable to the "coarse powder" of

* *Fluid Extract of Jalap.* The following process has been proposed by Prof. Procter. Take of jalap, in coarse powder, ℥xvi; sugar ℥viij; carbonate of potassa ℥ss; alcohol, water, each, *q. s.* Add to the jalap one pint of a mixture consisting of two parts of alcohol and one of water, and set aside for 24 hours. Then put the mixture into a percolator, and pour on it diluted alcohol until half a gallon has passed. Evaporate the filtered liquid one-half, add the sugar and carbonate of potassa, and evaporate to 12 fluidounces. Put the liquid, while warm, into a pint bottle, add four fluidounces of alcohol, and mix. The carbonate of potassa renders the resin soluble in water, and probably favourably qualifies the irritating properties of the jalap. A fluidrachm of this extract would represent a drachm of jalap, so that the dose should be from 15 to 30 minims. (*Am. Journ. of Pharm.*, xxix. 108.)—*Note to the eleventh edition.*

the British. The wood of the root yielded to Prof. Procter only 6·8 per cent. of extract, while the bark separated from the wood yielded 33 per cent. As the wood is of difficult pulverization, the inference is obvious, that, in powdering the roots, the ligneous portion may be rejected with advantage. (*Am. Journ. of Pharm.*, xiv. 270.) As a prolonged exposure of the infusion to the air is attended with the absorption of oxygen, and the production of insoluble apotheme, it is desirable that the evaporation should be conducted rapidly or in a vacuum. There scarcely appears to be occasion, in the case of rhatany, for heating and filtering the infusion before evaporation, the only use of which is to get rid of albumen, which is not among the recognised ingredients of the root.

Very inferior extracts of rhatany are often sold. Such is the South American extract, which has been occasionally imported. As the product obtained by decoction is greater than that afforded by the officinal plan, the temptation to substitute the former is not always resisted, although it has been shown to contain nearly 50 per cent. of insoluble matter. Some druggists prepare the extract with an alcoholic menstruum with a view to the greater product; but the extract thus prepared has from 20 to 30 per cent. less of the active principle than the officinal. A substance has been shown to us, said to have been imported as extract of rhatany from Europe, which was nearly tasteless, and was plausibly conjectured to be the dried coagulated matter of old tincture of kino. Indeed, we are informed that very little of the genuine extract, prepared according to the officinal directions, is to be found in the shops. From a notice by Prof. Procter in the *Am. Journ. of Pharm.* (May, 1862, p. 209), it would appear that the rhatany now imported is much inferior to that formerly in use, having a larger proportion of wood, and yielding much less extract; and, a specimen carefully manipulated by himself, gave but 9·14 per cent.

Extract of rhatany should have a reddish-brown colour, a smooth shining fracture, and a very astringent taste; and should be almost entirely soluble in water. Its virtues may be considered as in proportion to its solubility. It is much used for all the purposes for which the astringent extracts are employed. The dose is from ten to twenty grains.

Off. Prep. Syrupus Krameriæ, *U. S.* W.

EXTRACTUM LUPULI. *Br. Extract of Hop.*

"Take of Hop *one pound* [avoirdupois]; Rectified Spirit *one pint and a half* [Imperial measure]; Distilled Water *one gallon* [Imp. meas.]. Macerate the Hop in the Spirit for seven days; press out the tincture, filter, and distil off the spirit, leaving a soft extract. Boil the residual Hop with the Water for one hour, then express the liquor, strain, and evaporate by a water-bath to the consistence of a soft extract. Mix the two extracts, and evaporate at a temperature not exceeding 140° to a proper consistence." *Br.*

This is a great improvement on the old Lond. and Ed. process by maceration with water and evaporation. Alcohol is necessary for the exhaustion of the hop, and very cautious evaporation, to preserve the aroma in the extract. But since the discovery of the fact that the active properties of hops reside chiefly in the lupulin, the extract has been to a great extent superseded by that substance in this country, and has been little used. Lupulin may be advantageously substituted for it in all cases in which it was formerly employed. Mr. Brande says that the average yield of one cwt. of hops is 40 lbs. of the extract. The dose is from ten to thirty grains.

Under the inappropriate name of *humuline*, an extract has been prepared by first treating hops with alcohol and subsequently with water, evaporating the tincture and infusion separately, and mixing the products. (*Pharm. Journ.*, xiii. 231.)

EXTRACTUM NUCIS VOMICÆ ALCOHOLICUM. *U. S.* Ex-

TRACTUM NUCIS VOMICÆ. *Br., U. S.* 1850. *Alcoholic Extract of Nux Vomica. Extract of Nux Vomica.*

"Take of Nux Vomica, in fine powder, *twelve troyounces;* Alcohol *a sufficient quantity.* Mix the Nux Vomica with four fluidounces of Alcohol, and allow the mixture to stand for an hour. Then introduce it into a cylindrical percolator, and gradually pour Alcohol upon it until the tincture passes without bitterness. Distil off the alcohol, by means of a water-bath, until the tincture is reduced to half a pint, and evaporate this to the proper consistence." *U. S.*

"Take of Nux Vomica *one pound* [avoirdupois]; Rectified Spirit *a sufficiency.* Apply steam to the Nux Vomica until it is thoroughly softened, then dry rapidly, and reduce to fine powder. Exhaust the powder by boiling it with successive portions of the Spirit until the latter comes off nearly free from bitterness. Strain, distil off the spirit, and evaporate by a water-bath to the proper consistence." *Br.*

In both the U. S. and Br. Pharmacopœias the nux vomica is directed in fine powder; but in the latter only are we told how to reduce it to that state. Another method, formerly employed by the Ed. College, was to grind it in a coffee-mill. The method of percolation in the U. S. process is preferable to that of decoction in the British, for exhausting the drug. We prefer the simple British name, which was that of our Pharmacopœia of 1850, to the more prolix one adopted in the late revision. As there is no other extract of nux vomica, it appears to us to have been an unnecessary precision to add the epithet *alcoholicum*, which renders the title more unwieldy, without making it more distinctive. This is one of the few instances in which the U. S. Pharmacopœia deems a preliminary maceration advisable. It is said that, when the extract is kept in powder, it is apt to agglutinate into a tough mass. According to Zippel, this may be prevented by adding a little water before the close of the evaporation, and then continuing the evaporation to dryness. (*Arch. der Pharm.*, July 24, 1859.)

This extract is an active preparation, though not always of uniform strength, owing to the variable proportion of strychnia in the nux vomica. M. Recluz obtained from sixteen ounces of nux vomica the average product of one ounce and a quarter. The dose of the extract is from half a grain to two grains, to be repeated three times a day.* W.

EXTRACTUM OPII. *U. S., Br. Extract of Opium.*

"Take of Opium *twelve troyounces;* Water *five pints.* Cut the Opium into small pieces, macerate it for twenty-four hours in a pint of the Water, and reduce it to a soft mass by trituration. Express the liquid, and treat the residue with each of the four remaining pints of water successively in the same manner. Having mixed the liquids, filter the mixture, and evaporate, by means of a water-bath, to the proper consistence." *U. S.*

"Take of Opium, in thin slices, *one pound* [avoirdupois]; Distilled Water *six pints* [Imperial measure]. Macerate the Opium in two pints of the Water for twenty-four hours, and express the liquor. Reduce the Opium to a uniform pulp, macerate it again in two pints of the Water for twenty-four hours, and express. Repeat the operation a third time. Mix the liquors, strain through flannel, and evaporate by a water-bath to a proper consistence." *Br.*

These processes are essentially the same. An advantage of the preparation is that, by the solubility of the extract in water, it affords a convenient method of

* Professor Procter informs us, as the result of his own observation, that in the alcoholic extract of nux vomica there is a considerable proportion of fixed oil (ʒiij in ℥xvi of the seeds), which will not remain mixed with the other ingredients, becoming fluid in summer, and concreting in cold weather. This he thinks should be separated from the extract, and shaken with a little diluted alcohol which takes from it any adhering active matter. The washings should be evaporated, and the residuum mixed with the extract, the fatty matter being thrown away.—*Note to the tenth edition.*

obtaining quickly an aqueous solution of the active ingredients of opium. It is exceedingly doubtful whether anything is left behind after the opium has been exhausted by water, which materially modifies the action of its anodyne principle; and the extract probably has no advantage on this account over opium. Nor has it the advantage of greater uniformity; as the gum, extractive, &c., taken up by the water, bear no fixed proportion to the active ingredients. But, as purely aqueous preparations of opium have been found to agree better with certain individuals than opium alone or its alcoholic preparations, there is reason to believe that there are in the crude drug one or more principles, capable of causing nausea, headache, nervous disturbance, &c., which are insoluble in water, though extracted by alcohol or ether. M. Guibourt states that this extract, when kept, is apt to swell up, owing, as he at first supposed, to the fermentation of glucose; but he now ascribes the phenomenon to the change of meconic acid into the parameconic, with the escape of carbonic acid. (*Journ. de Pharm.*, Août, 1860, p. 138.)

Denarcotized Extract of Opium. Under the impression that the stimulating and unpleasant effects of opium are owing to the narcotina, it has been proposed to separate that principle by treating the extract with ether, which dissolves the narcotina, and leaves the morphia with the other ingredients. Robiquet employed cold ether; but M. Dublanc, convinced that the whole of the narcotina was not thus extracted, proposed the following plan. "Take of watery extract of opium 16 ounces; dissolve it in 8 ounces of distilled water; introduce the solution into the water-bath of a still; pour upon it 104 ounces of pure ether; distil off 24 ounces of the ether; take apart the apparatus, and decant the ether which floats on the top of the extract; wash the latter while hot with the distilled ether; concentrate the residual matter, dissolve it in distilled water, filter the solution, and evaporate to a proper consistence." It is doubtful whether any useful end is gained by this operation commensurate with its costliness; as there is reason to think that narcotina does not in fact produce the unpleasant effects which have been ascribed to it; and the noxious principles in opium, of which ether is capable of depriving it, are probably left behind, for the most part at least, in the formation of the aqueous extract.

Recluz obtained from sixteen ounces of opium an average product of nine ounces by hot water and six by cold; and Prof. Procter informs us that the U. S. formula usually yields about seven and a half ounces from the same quantity. The dose of the extract of opium is about one-half that of opium itself.*

* *Extractum Papaveris. Extract of Poppy Capsules.* Though this has been discarded from the British Pharmacopœia, its former extensive use, and supposed importance, entitle it to some notice. The following was the London process. "Take of Poppy [capsules], freed from their seeds and bruised, *fifteen ounces;* boiling Distilled Water *a gallon* [Imperial measure]. Macerate for twenty-four hours; then boil down to four pints, and strain the liquor while hot; lastly, evaporate to the proper consistence." *Lond.*

Mr. Brande observes, in relation to this extract, that if prepared over the open fire it is often nearly inert. He states, moreover, that it is apt to be of a troublesome consistence, too hard to be formed into pills, and too tough to be pulverized; and advises that it should always be carefully dried till it becomes sufficiently brittle to admit of being reduced to powder. One cwt. of the capsules, without the seeds, yields, according to this author, the average product of 35 pounds of extract. M. Meurein gives particular directions for making an alcoholic extract of poppy capsules, which may be consulted with advantage by those who may be called on to supply any demand for this preparation. (See *Journ. de Pharm.*, 3*e sér.*, xxiii. 341.) Mr. Joseph Ince recommends that the strained hot decoction, after having been brought to a syrupy consistence, should be diluted with eight times its quantity of water, then filtered, and afterwards evaporated. Made in this way the extract will keep well. (*Pharm. Journ.*, xiv. 489.) We are told that an extract is prepared in this country from the whole herb, cut after the fruit has formed, but while it is yet green. The capsules exclusively should be used; and the best time for collecting them is immediately after they have begun to become yellowish. This extract possesses the virtues of opium, but is much inferior and less uniform in strength. The dose is from five to ten grains.

Off. Prep. Emplastrum Opii, *U. S.;* Extractum Opii Liquidum, *Br.;* Trochisci Opii, *Br.* W.

EXTRACTUM PODOPHYLLI. *U. S. Extract of May-apple.*

"Take of May-apple, in moderately fine powder, *twelve troyounces;* Alcohol *four pints;* Water *a sufficient quantity.* Introduce the powder, previously mixed with three fluidounces of Alcohol, into a conical percolator, and pour upon it the remainder of the Alcohol. When the tincture ceases to pass, pour gradually upon the powder sufficient Water to keep its surface covered, until four pints of tincture have passed. Set this aside, and continue the percolation until six pints of infusion have been obtained. Distil off the alcohol from the tincture, and evaporate the infusion, until the liquids respectively have been brought to the consistence of thin honey; then mix them, and evaporate to the proper consistence." *U. S.*

This is possessed of the purgative properties of the root, and may be given in the dose of from five to fifteen grains. It might be substituted in all cases for the extract of jalap.

From experiments made by Mr. John R. Lewis, it is probable that the alcoholic extract would be much more powerful as a purgative than the officinal preparation; but it does not follow that it would be more serviceable. (See *Am. Journ. of Pharm.*, xix. 170.) W.

EXTRACTUM QUASSIÆ. *U. S., Br. Extract of Quassia.*

"Take of Quassia, in moderately fine powder, *twelve troyounces;* Water *a sufficient quantity.* Moisten the Quassia with four fluidounces of Water, pack it in a conical percolator, and gradually pour Water upon it until the infusion passes but slightly impregnated with the properties of the Quassia. Boil down the liquid to three-fourths of its bulk; then strain, and, by means of a water-bath, evaporate to the proper consistence." *U. S.*

"Take of Quassia, in moderately fine powder, *one pound* [avoirdupois]; Distilled Water *a sufficiency.* Macerate the Quassia in eight fluidounces of the Water for twelve hours; then pack in a percolator, and add Distilled Water until the Quassia is exhausted. Evaporate the liquor; filter before it becomes too thick; and again evaporate by a water-bath to a proper consistence." *Br.*

According to M. Recluz, sixteen ounces of Quassia yield by infusion in water seven drachms of extract; by maceration in alcohol of 19° Baumé, two ounces five drachms and a half. The difference between these quantities is so great that we suspect some mistake in the table of the Dictionnaire des Drogues from which we quote.

The extract of quassia is dark-brown or black, and excessively bitter. It is apt to become dry and disposed to crumble by time. It concentrates a greater amount of tonic power within a given weight than any other extract of the simple bitters; and may, therefore, be given with great advantage in cases in which it is desirable to administer this class of substances in as small a bulk, and with as little inconvenience to the patient as possible. The dose is about five grains, to be given in the form of pill. W.

EXTRACTUM RHEI ALCOHOLICUM. *U. S.* Extractum Rhei. *Br., U. S.* 1850. *Alcoholic Extract of Rhubarb. Extract of Rhubarb.*

"Take of Rhubarb, in moderately fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with four fluidounces of the Alcohol, pack it in a conical percolator, and gradually pour upon it, first the remainder of the Alcohol, and afterwards Diluted Alcohol, until twelve fluidounces of tincture have been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to six fluidounces.

Continue the percolation with Diluted Alcohol until the tincture passes nearly tasteless. Evaporate this in a porcelain vessel, by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup. With this mix the tincture first obtained, and continue the evaporation until the mixture is reduced to the proper consistence." *U. S.*

"Take of Rhubarb, sliced or bruised, *one pound* [avoirdupois]; Rectified Spirit *ten fluidounces* [Imperial measure]; Distilled Water *five pints* [Imp. meas.]. Mix the Spirit and the Water, and macerate the Rhubarb in the mixture for four days; then decant, press, and set by that the undissolved matter may subside; pour off the clear liquor, filter the remainder, mix the liquors, and evaporate by a water-bath, at a temperature not exceeding 160°, to a proper consistence." *Br.*

Rhubarb yields all its active matter to water and alcohol; but, unless the evaporation is performed with great care and with a moderate heat, it is certain that the purgative principle is, to a greater or less extent, injured or dissipated in the process; and the extract may thus become even less efficient than the root. Among other consequences which result from the boiling temperature, is the formation of a compound of the tannin and starch, which is insoluble in cold water, and upon its precipitation probably carries with it a portion of the purgative principle. There is, moreover, reason to believe that this principle is volatilizable by heat, and that a portion of it escapes with the vapour. When properly prepared, the extract has decidedly the peculiar odour of rhubarb. The dose of the extract is from ten to thirty grains. W.

EXTRACTUM SENEGÆ ALCOHOLICUM. *U.S. Alcoholic Extract of Seneka.*

"Take of Seneka, in moderately fine powder, *twelve troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with four fluidounces of Diluted Alcohol, pack it in a conical percolator, and gradually pour upon it Diluted Alcohol until three pints of tincture have passed. Evaporate this, by means of a water-bath, to the proper consistence." *U. S.*

This is a good preparation of Seneka, possessing all its virtues in a concentrated form. There seems to have been no necessity for burdening the title with the epithet "alcoholicum"; as there is no other officinal extract. For its uses, see Senega in *Part I.* The dose is from one to three grains. W.

EXTRACTUM STRAMONII. *U.S.* EXTRACTUM STRAMONII FOLIORUM. *U. S.* 1850. *Extract of Stramonium. Extract of Stramonium Leaves.*

"Take of Stramonium Leaf *twelve troyounces.* Bruise it in a stone mortar, sprinkling on it a little water, and express the juice; then, having heated this to the boiling point, strain, and evaporate, at a temperature not exceeding 160°, to the proper consistence." *U. S.*

Like all the other inspissated narcotic juices, this is an uncertain preparation, varying in strength according to the care used in conducting the process, and the season at which the leaves are collected. The reader will find at page 1086, and in the preliminary observations on the Extracts, some general rules which will prove useful in conducting this process. The insoluble matter separated from the expressed juice by filtering, and that coagulated by heat, may be advantageously rejected; as, according to the observations of MM. Solon and Soubeiran, they are nearly or quite inert. This is done in the present process, which as well in this respect, as in directing the temperature not to exceed 160°, is an improvement of the old one. M. Recluz obtained half an ounce of extract from sixteen ounces of the leaves. The dose is a grain night and morning, to be gradually increased till it affects the system.

Off. Prep. Unguentum Stramonii, *U. S.* W.

EXTRACTUM STRAMONII. *Br.* EXTRACTUM STRAMONII SEMINIS. *U. S.* 1850. *Extract of Stramonium. Extract of Stramonium Seed.*

"Take of Stramonium Seeds, in coarse powder, *one pound* [avoirdupois]; Proof Spirit *a sufficiency.* Pack the powder in a percolator, and add the Spirit until the powder is exhausted. Distil off the Spirit, and evaporate the residue by a water-bath to a proper consistence." *Br.*

Though with the same name, this is a very different preparation from the preceding one of the U. S. Pharmacopœia, which is the inspissated juice of the leaves; while the British is an alcoholic extract of the seeds. The latter was formerly officinal with us under the name of *Extractum Stramonii Seminis*, while that now named Extractum Stramonii in the U. S. Pharmacopœia, was then denominated *Extractum Stramonii Foliorum.* Two things are to be regretted in the changes, in reference to the extracts of stramonium, made in the revision of the Pharmacopœia of 1850; first, that the extract of the seeds, which is perhaps the most efficient preparation of stramonium, should have been abandoned, and, secondly, that the old name of Extractum Stramonii Foliorum should not have been retained; for as the nomenclature now stands, there must be inevitable confusion, only to be guarded against by great care.

This is an excellent preparation, not only stronger, but more uniform, and therefore more to be relied on than any other officinal extract of stramonium. As the seeds yield their virtues more freely to spirit than to water alone, the Br. Pharmacopœia has very properly adopted proof spirit as the menstruum. According to the table of Recluz, sixteen ounces of the seed afford two ounces and two drachms of extract by maceration in diluted alcohol, and one ounce and a half by decoction. The dose to begin with is the quarter or half of a grain, twice a day, to be gradually increased. W.

EXTRACTUM STRAMONII ALCOHOLICUM. *U. S. Alcoholic Extract of Stramonium.*

"Take of Stramonium Leaf, recently dried and in fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Introduce the powder, previously mixed with one-third of the Alcohol, into a conical percolator, and gradually pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour on Diluted Alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted Alcohol until two pints more of tincture have passed, or until the powder is exhausted; then evaporate, by means of a water-bath, at a temperature not exceeding 160°, to the consistence of syrup. With this mix the three fluidounces of tincture first obtained, and continue the evaporation, at a temperature not exceeding 120°, until the mixture is reduced to the proper consistence." *U. S.*

There is no such superiority in this preparation over the inspissated juice as to have called for a separate process; especially as the Stramonium plant is so abundant that there can be nowhere any difficulty in obtaining the leaves fresh at the proper season. It is, we think, a poor substitute for the abandoned extract of the seeds. The dose is a grain. W.

EXTRACTUM TARAXACI. *U. S., Br. Extract of Dandelion.*

"Take of Dandelion, gathered in September, *sixty troyounces.* Slice the Dandelion, and bruise it in a stone mortar, sprinkling on it a little water, until reduced to a pulp. Then express and strain the juice, and evaporate it in a vacuum, or in a shallow dish over a water-bath, to the proper consistence." *U. S.*

"Take of Fresh Dandelion Root *four pounds* [avoirdupois]. Crush the Root; press out the juice, and allow it to deposit; heat the clear liquor to 212°, and

maintain the temperature for ten minutes; then strain, and evaporate by a water-bath, at a temperature not exceeding 160°, to a proper consistence." *Br.*

This extract is undoubtedly stronger, prepared from the root alone than from the whole plant. It is important that the root should be collected at the right season. The juice expressed from it in the spring is thin, watery, and of a feeble flavour; in the latter part of the summer, and in autumn, thick, opaque, cream-coloured, very bitter, and abundant, amounting to one-third or one-half its weight. It may be collected in August, and afterwards until severe frost. According to Mr. Squire, frost has the effect of diminishing the bitterness and increasing the sweetness of the root. An extract prepared by inspissating the juice, as in the present U. S. and Br. processes, is much more efficient than that prepared in the old way by decoction. The inspissation should be effected by exposing the juice in shallow vessels to a current of warm dry air, or by evaporation in a vacuum, and should not be unnecessarily protracted. Long exposure, during evaporation, changes the bitterness of the juice into sweetness, which is a sign of inferiority. In the British process, it is wisely directed that, before the evaporation of the juice, it shall be exposed for a short time to a heat sufficient to coagulate the albumen, which is then separated and rejected as useless, and indeed injurious by favouring decomposition. As often found in the shops, the extract is dark-coloured, sweet, and in all probability nearly inert. Mr. Houlton took more than an ounce of it in a day, without any sensible effect. (*Pharm. Journ.*, i. 421.) When prepared from the root and leaves together, it has a greenish colour. Mr. Brande states that one cwt. of the fresh root affords from twenty to twenty-five pounds of extract by decoction in water. The expressed juice yields from 11 to 25 per cent. of extract, the greatest product being obtained in November, and the least in April and May.

This extract deteriorates by keeping, and should, therefore, be renewed annually. It is most conveniently given dissolved in cinnamon or mint water. The dose is from a scruple to a drachm three times a day. W.

EXTRACTUM VALERIANÆ ALCOHOLICUM. *U. S.* *Alcoholic Extract of Valerian.*

"Take of Valerian, in fine powder, *twelve troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with four fluidounces of Alcohol, pack it in a percolator, and gradually pour upon it the remainder of the Alcohol. When the liquid has all been absorbed by the powder, pour on Diluted Alcohol until a pint of tincture has been obtained. Set this aside in a warm place, and allow it to evaporate spontaneously until reduced to three fluidounces. Continue the percolation with Diluted Alcohol until two pints more of tincture have passed, and evaporate this, by means of a water-bath, to the consistence of syrup. Lastly, mix the two liquids, and continue the evaporation, at a temperature not exceeding 120°, until the mixture is reduced to the proper consistence." *U. S.*

This extract contains most of the active matter of the root, though a portion of the volatile oil may be lost in the process. It may be used for obtaining the effects of valerian on the system. According to Vielguth and Nentwich, the root yields 23 per cent. of its weight to cold diluted alcohol by percolation. The dose of the extract is from ten to thirty grains. W.

EXTRACTA FLUIDA.

Fluid Extracts.

These were first introduced into the U. S. Pharmacopœia of 1850, as a distinct class of preparations; the fluid extract of sarsaparilla being the only one previously directed, either in our own officinal code, or by the British Colleges.

Their distinctive character is the concentration of the active ingredients of medicinal substances into a small bulk, in the liquid form. Independently of the greater convenience of administration, the advantage of this class of preparations is that, the evaporation not being carried so far as in the ordinary extracts, the active principles are less liable to be injured by heat. The main difficulty, in relation to them, is the liability of substances in the liquid state to undergo spontaneous decomposition. This is counteracted in some of the fluid extracts by means of sugar, in others by alcohol, and in others, again, by a mixture of the two. Formerly a class of preparations was united with the fluid extracts, which in the present edition of the Pharmacopœia hold a distinct position, under the name of *oleoresins*. In these the extracted matter is in its own nature preservative; but they will be considered elsewhere. In a few of the fluid extracts in which acetic acid is used as one of the menstrua, this also probably contributes to their preservation. In all of them alcohol or alcohol and water are employed as the menstruum, one being preferred to the other according to the character of the active principle or principles to be extracted. In all, moreover, the extraction is effected by percolation; and in the evaporation great care is taken not to injure the product by too great a heat. Though the greater portion of the alcohol is evaporated, a portion generally remains, which contributes towards the preservation of the preparation; but, as this alone is often insufficient, it is necessary to have recourse to sugar, which has the subsidiary advantage of improving the flavour. In the fluid extracts, however, instead of two pounds of sugar to each pint of the liquid, as in the case of the ordinary syrups, it is generally sufficient to add an ounce for every fluidounce. The British Pharmacopœia has a few of these preparations, which it prefers to name *Extracta Liquida*.

For valuable remarks upon the Fluid Extracts, and many important practical rules in the preparation of the several articles of the class, the reader is referred to reports by Prof. Procter in the *Proceedings of the American Pharmaceutical Association* for 1859 (p. 265), and for 1863 (p. 222). We would strongly impress on practical pharmaceutists the great importance of fulfilling carefully every officinal direction in the several formulas which follow, and especially of conducting most cautiously the process of percolation, upon the due performance of which the efficiency of the product so much depends. Properly prepared, the fluid extracts are among the most efficacious, convenient, and elegant medicinal preparations; whereas, if carelessly or ignorantly made, there are probably none which would be more likely to deceive the hopes of the practitioner. W.

EXTRACTUM BELÆ LIQUIDUM. *Br. Liquid Extract of Bael.*

"Take of Bael *one pound* [avoirdupois]; Distilled Water *twelve pints* [Imperial measure]; Rectified Spirit *two fluidounces*. Macerate the Bael for twelve hours in one-third of the Water; pour off the clear liquor; repeat the maceration a second and third time for one hour in the remaining two-thirds of the Water; press the mass; and filter the mixed liquors through flannel. Evaporate to fourteen fluidounces; and, when cold, add the Rectified Spirit." *Br.*

This is a new officinal of the British Pharmacopœia, of which very little is known in the United States. It is one of the forms in which the new India remedy bael is employed, and the reader is referred to the article on that subject in *Part I.* Each fluidounce of the extract represents an avoirdupois ounce of the medicine, and the dose is from one to four fluidrachms. W.

EXTRACTUM BUCHU FLUIDUM. *U. S. Fluid Extract of Buchu.*

"Take of Buchu, in moderately fine powder, *sixteen troyounces;* Alcohol *a sufficient quantity*. Moisten the Buchu with six fluidounces of Alcohol, introduce it into a cylindrical percolator, press it firmly, and gradually pour Alcohol upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints more of tincture have been obtained. Eva-

porate this, by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces, and mix it with the reserved tincture. Allow the mixture to stand for twenty-four hours, and filter through paper." *U. S.*

In consequence of the tenacity of the leaves, it is somewhat difficult to powder them in a mortar, and it will be convenient to resort to a mill for the purpose. As the most active ingredient of buchu is volatile, the direction in the formula to set aside the first portion of tincture obtained, which is a highly concentrated solution, is peculiarly important; for, if it were subjected to evaporation, much of the volatile oil would necessarily escape. The facility of obtaining such concentrated solutions by means of percolation is one of the greatest recommendations of the process, and is especially valuable in the preparation of the fluid extracts. The tincture subsequently obtained probably contains a large proportion of the fixed ingredients of the leaves, and will, therefore, allow of concentration without material loss. This is one of the fluid extracts in which alcohol acts at once as the menstruum and the preservative agent. The preparation is, indeed, nothing more than a very concentrated tincture; and, as buchu is itself a stimulant agent, and generally exhibited in cases admitting or requiring stimulation, there is no medicinal incompatibility in the case.

This fluid extract is clear, at first greenish, but at length of a dark reddish-brown colour, and possessed in a high degree of the sensible properties of the leaves. It is said to acquire the odour of mint when long kept, showing that some change takes place in its volatile oil. Each fluidounce of the fluid extract represents a troyounce of the leaves; and the dose is twenty or thirty minims, to be given diluted with water. W.

EXTRACTUM CIMICIFUGÆ FLUIDUM. *U. S. Fluid Extract of Cimicifuga.*

"Take of Cimicifuga, in fine powder, *sixteen troyounces;* Stronger Alcohol *a pint and a half;* Diluted Alcohol *a sufficient quantity.* Moisten the Cimicifuga with four fluidounces of the Stronger Alcohol, introduce it into a conical percolator, pour upon it the remainder of the Stronger Alcohol, and, when the whole of this has entered the powder, gradually add Diluted Alcohol until a pint and a half of tincture have passed. Set this aside, in a shallow vessel, in a warm place, until reduced by spontaneous evaporation to twelve fluidounces. Continue the percolation with Diluted Alcohol, until two pints more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces; then add the tincture first obtained very gradually so as to avoid precipitation, allow the mixture to stand for twenty-four hours, and filter through paper." *U. S.*

This is essentially the process of Prof. Procter, published in the eleventh edition of the U. S. Dispensatory (*page* 226); stronger alcohol being substituted as the first menstruum for a mixture of alcohol and ether. There can be little doubt, we think, that cimicifuga depends, for its remedial effects, in part upon a volatile principle. Hence the necessity for submitting the pint and a half of concentrated tincture first obtained to spontaneous evaporation, without the aid of the warm bath subsequently employed. As cimicifuga is often given in cases requiring rather a sedative than a stimulant influence, it is desirable to have no more alcohol in the preparation than may be necessary for its preservation. On this account, the first tincture with alcohol is allowed to diminish one-half by spontaneous evaporation; and the process is completed with diluted alcohol, which loses nearly all its spirit in the subsequent concentration. As the result, in the latter case, is little more than a strong aqueous solution, there is some precipitation of resin when the first alcoholic solution is added to it, unless care is taken to make the mixture very gradually. This fluid extract is of a very dense reddish-brown colour, and clear, yet disposed to deposit a resinoid sediment on

standing. It has the peculiar odour and taste of cimicifuga. A fluidounce of it represents a troyounce of the root, and probably contains all or nearly all its virtues. The dose is from thirty minims to a fluidrachm. W.

EXTRACTUM CINCHONÆ FLUIDUM. *U. S.* EXTRACTUM CINCHONÆ FLAVÆ LIQUIDUM. *Br.* *Fluid Extract of Cinchona. Liquid Extract of Yellow Cinchona.*

"Take of Yellow Cinchona, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *twenty troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Cinchona with ten fluidounces of Diluted Alcohol, allow it to stand for half an hour, pack it firmly in a cylindrical percolator, and gradually pour upon it Diluted Alcohol until four pints of tincture have been obtained. Evaporate this, by means of a water-bath, to two pints; then add the Sugar, evaporate again to two pints, and strain the liquid while hot." *U. S.*

"Take of Yellow-Cinchona Bark, in coarse powder, *one pound* [avoirdupois]; Distilled Water *a sufficient quantity;* Rectified Spirit *one fluidounce.* Macerate the Bark in two pints [Imperial measure] of the Water for twenty-four hours, stirring frequently; then pack in a percolator, and add more Water, until twelve pints [Imp. meas.] have been collected, or a sufficient quantity to exhaust the bark. Evaporate the liquor at a temperature not exceeding 160° to a pint; then filter through paper, and continue the evaporation to three fluidounces, or until the sp. gr. of the liquid is 1·200. When cold, add the Spirit gradually, constantly stirring. The sp. gr. should be about 1·100." *Br.*

Of these two formulas, the first is decidedly preferable. It is essentially that of Mr. Alfred B. Taylor, of Philadelphia, and was described in the eleventh edition of this work (*page* 272). The British Pharmacopœia uses water only as the menstruum, while it adds alcohol to the liquid to preserve it. In the U. S. process diluted alcohol is used as the menstruum, and the alcohol afterwards almost all driven off, sugar being used as the preservative agent. Now it is well known that Peruvian bark cannot be exhausted by water alone; and, though by its use as a menstruum the resin and cinchonic red are mainly left behind, so also is a considerable proportion of the alkaloids. By using diluted alcohol the U. S. Pharmacopœia extracts all the virtues of the bark, and, though it may also take up some of the resin and cinchonic red, it avoids any gummy matter that may be present, and gets rid of most of the other inert matters during the evaporation. The British preparation contains one-fourth of alcohol, and is in fact a tincture; the U. S. fluid extract is a highly concentrated infusion preserved by sugar. Of the former, four fluidounces are intended to represent an avoirdupois pound or sixteen ounces of the bark; but certainly fail to do so, and to an indefinite degree. Of the latter, two fluidounces actually represent an ounce of the bark, and may be relied on, if well prepared, to produce all its effects. The direction, in the U. S. process, to strain while hot is necessary; because a portion of the cinchonic red and cinchotannates of the alkaloids, which are much more soluble in the hot than in the cold liquid, is deposited when it cools. The U. S. fluid extract is consequently somewhat turbid, at least deposits a sediment on standing, and should be shaken when administered. When shaken, it is opaque, and of a light brownish-red colour, as if prepared rather from red than Calisaya bark. The dose equivalent to a drachm of the bark is two fluidrachms; and to produce an antiperiodic effect, at least two fluidounces should be taken between the paroxysms. W.

EXTRACTUM COLCHICI RADICIS FLUIDUM. *U. S.* *Fluid Extract of Colchicum Root.*

"Take of Colchicum Root, in fine powder, *sixteen troyounces*; Alcohol, Water, each, *a sufficient quantity* Mix two measures of Alcohol with one of Water, moisten the Colchicum Root with six fluidounces of the mixture, press it mode-

rately in a conical percolator, and gradually pour the mixture upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints more of tincture have been obtained. Evaporate this to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

EXTRACTUM COLCHICI SEMINIS FLUIDUM. *U. S. Fluid Extract of Colchicum Seed.*

"Take of Colchicum Seed, in moderately fine powder, *sixteen troyounces;* Alcohol, Water, each, *a sufficient quantity.* Mix two measures of Alcohol with one of Water, moisten the Colchicum Seed with six fluidounces of the mixture, press it firmly in a conical percolator, and pour the mixture upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints more of tincture have been obtained. Evaporate this to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

These two preparations, the one of the cormus, the other of the seeds of Colchicum, are made precisely in the same manner, and are nothing more nor less than strong tinctures. Considering that we had one tincture, two wines, and two extracts of Colchicum, all efficient preparations, these additions to our pharmacy might have been spared, unless some peculiar advantage could have been gained from them. They are, however, well made, and no doubt concentrate the virtues of colchicum within a small space. The proportion of two measures of alcohol to one of water was preferred to that of equal measures, as in diluted alcohol, because the latter was found to extract an inert matter from the material operated on, which is left behind by the former. The process is one of those published by Prof. Procter in the *Proceedings of the American Pharmaceutical Association* for 1859 (p. 269).

The fluid extracts of colchicum are of a deep-brown colour, and somewhat turbid. In relation to that from the seeds, Mr. Maisch states that it cannot be obtained clear by filtration through either a dry or moist filter; but, on being allowed to stand for some days, it separates into two layers, the upper greenish-brown and of an oily nature, on the removal of which the lower layer is left permanently clear. (*Am. Journ. of Pharm.*, March, 1864, p. 97.) Supposing the root and seeds to be exhausted by the menstruum employed, and none of the active matter to be lost in the evaporation, a troyounce of each is represented by a fluidounce of the fluid extract, the dose of which, therefore, would be from two to eight minims. W.

EXTRACTUM CONII FLUIDUM. *U. S. Fluid Extract of Hemlock.*

"Take of Hemlock, recently dried and in fine powder, *sixteen troyounces;* Acetic Acid *half a fluidounce;* Diluted Alcohol *a sufficient quantity.* Mix the Acid with three pints of Diluted Alcohol, moisten the powder with half a pint of the mixture, pack it in a conical glass percolator, and gradually pour the mixture upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation, first with the remainder of the mixture, and afterwards with Diluted Alcohol, until three pints more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

This process had the same origin as the preceding. It is scarcely possible that a liquid preparation of hemlock could be made, in which the virtues of the drug should be more satisfactorily concentrated. By the use of acetic acid we probably increase the solvent powers of the menstruum, contribute to protect the alkaloid against decomposition during the concentration, and aid the alcohol in preserving the fluid extract when completed. Prof. Procter states that the tendency of the alkaloid to decomposition is entirely controlled by acetic acid at any temperature below 150° F. (*Proceedings of the Am. Pharm. Assoc.* 1859,

p. 272.) From the great facility with which conia is destroyed by heat, it is an important provision in the process, to make first as highly concentrated a tincture as possible, containing most of the virtues of the leaves, to be reserved for admixture with the portion which has undergone evaporation. But the fluid extract must partake of the uncertainty of the leaves themselves, and hence the importance of using them immediately after they are dried, and of taking care that they should be properly dried. It is a thick but mobile, very dark liquid, with a yellowish tint in thin layers, and having in a decided degree the peculiar odour of the leaves. When treated with an alkali, it should give out strongly the mouse-like odour of the alkaloid conia; but too frequently this essential characteristic is wanting, either from defect in the leaves used, or some error in performing the process. In a specimen which came under our notice, having all the other qualities of the fluid extract in perfection, this mouse-like odour, on contact with potassa, was entirely wanting. One fluidounce contains the active matter of a troyounce of the leaves; and four or five minims may be given as a commencing dose, to be somewhat rapidly increased until its effects are felt. W.

EXTRACTUM DULCAMARÆ FLUIDUM. *U. S.* *Fluid Extract of Bittersweet.*

"Take of Bittersweet, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *ten troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Bittersweet with half a pint of Diluted Alcohol, pack it in a conical percolator, and pour upon it Diluted Alcohol until three pints of tincture have passed. Evaporate this, by means of a water-bath, to a pint, add the Sugar, evaporate again to a pint, and strain the liquid while hot." *U. S.*

In this fluid extract, as, in view of the sedative properties of the medicine, is obviously indicated, the alcohol employed in extracting the virtues of the twigs is almost entirely evaporated, and sugar is depended on for the prevention of spontaneous change. By straining while hot, the active matter deposited on cooling is retained in the preparation, which is therefore somewhat turbid, and should be shaken when administered. It is a thickish, almost syrupy liquid, of a dark-olive hue, with the sensible properties of the bittersweet in a concentrated state. One fluidounce represents a troyounce of the twigs. The dose is from thirty minims to a fluidrachm, three or four times a day, and gradually increased if necessary. W.

EXTRACTUM ERGOTÆ FLUIDUM. *U. S.* EXTRACTUM ERGOTÆ LIQUIDUM. *Br.* *Fluid Extract of Ergot. Liquid Extract of Ergot.*

"Take of Ergot, in fine powder, *sixteen troyounces;* Acetic Acid *half a fluidounce;* Diluted Alcohol *a sufficient quantity.* Mix the Acid with three pints of Diluted Alcohol, and, having moistened the Ergot with four fluidounces of the mixture, introduce it into a conical glass percolator, pressing moderately, and gradually pour the mixture upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation, first with the remainder of the mixture, and afterwards with Diluted Alcohol, until three pints more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

"Take of Ergot, in coarse powder, *one pound* [avoirdupois]; Ether *one pint* [Imperial measure]; Distilled Water *three pints and a half* [Imp. meas.]; Rectified Spirit *eight fluidounces.* Shake the Ether in a bottle with half a pint [Imp. meas.] of the Water, and after separation decant the ether. Place the Ergot in a percolator, and free it from its oil by passing the washed ether through it. Remove the marc, and digest it in three pints of the Water at 160° for twelve hours. Press out, strain, and evaporate the liquor to nine fluidounces;

and, when cold, add the Spirit. Allow it to stand for an hour to coagulate, then filter. The product should measure sixteen fluidounces." *Br.*

These are not identical preparations. The U. S. fluid extract is probably the best officinal preparation of ergot, having all the virtues of the medicine in a concentrated state. It was first suggested by Mr. Jos. Laidley, of Richmond, Va.; but the process has since been variously modified by different writers, and in its present state was taken from the Proceedings of the American Pharmaceutical Association before referred to. Diluted alcohol dissolves all the active matter of ergot, leaving its oil behind, and the tincture first obtained holding most of the active principles, is reserved without concentration; while the acetic acid has the effect of counteracting the injurious influence of the heat used in concentrating the tincture subsequently passed, probably by forming fixed salts with the alkaloids. In the British process, the first step is to dissolve out the oil with ether previously deprived of alcohol by washing with water; because ordinary ether, in consequence of the alcohol it contains, dissolves a portion of the active matter along with the oil. The remainder of the process consists simply in forming an infusion with the residue of the ergot by digesting it with water, and then adding the spirit to preserve it.

The U. S. fluid extract of ergot is a clear, very dark reddish-brown liquid, having the taste of ergot, but without its fishy odour, owing to the fixation of the alkaloid propylamia, upon which that odour depends. On the addition, however, of solution of potassa, the odour is strongly developed, and the alkaloid escapes so largely that, if muriatic acid be held near it, a cloud of muriate of propylamia will be perceived. This may be considered as a good test of the efficiency of the preparation; for, though all the virtues of ergot do not depend on its volatile alkaloid, yet, if this is retained in the fluid extract, there can be little doubt that the other more fixed principles will be retained also. One fluidounce of the preparation, made by the U. S. process, represents a troyounce of the ergot, according to the British, an avoirdupois ounce. The dose is from ten to twenty minims. W.

EXTRACTUM FILICIS LIQUIDUM. *Br. Liquid Extract of Fern.*

This being properly an oleoresin, will be considered under the head of the *Oleoresinæ*, to which the reader is referred.

EXTRACTUM GENTIANÆ FLUIDUM. *U. S. Fluid Extract of Gentian.*

"Take of Gentian, in moderately fine powder, *sixteen troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Gentian with six fluidounces of Diluted Alcohol, introduce it into a conical percolator, pressing moderately, and pour upon it Diluted Alcohol until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints more of tincture have been obtained. Evaporate this, by means of a water-bath, to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

This is a concentrated tincture of gentian, transparent, reddish-brown, with the smell and taste of the root, of which a troyounce is represented by a fluidounce of the preparation. It may be questionable whether it was needed, though it has the advantage that we may obtain from it the tonic effects of the drug, with less alcohol than in an equivalent quantity of the tincture; and pharmaceutically it affords a convenient method of giving to mixtures the tonic properties of gentian when required. The dose is from ten to thirty or forty minims. W.

EXTRACTUM HYOSCYAMI FLUIDUM. *U. S. Fluid Extract of Henbane.*

"Take of Henbane Leaf, in fine powder, *sixteen troyounces;* Alcohol, Water, each, *a sufficient quantity.* Mix two measures of Alcohol with one of Water,

moisten the powder with six fluidounces of the mixture, pack it firmly in a conical percolator, and gradually pour the mixture upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation with the same mixture until two pints and a half more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

Like the preceding fluid extract, this is a concentrated alcoholic tincture, in which the menstruum instead of being diluted alcohol, is somewhat stronger, consisting of two measures of alcohol to one of water. It is clear at first, though apt to become somewhat turbid, is of a dark-brown colour, and possessed of the taste and smell of the leaves in a high degree. It was first proposed by Mr. Ch. A. Smith of Cincinnati (*Am. Journ. of Pharm.*, xxv. 410); but the formula is that of Prof. Procter, taken from the *Proceedings of the American Pharmaceutical Association* for 1859. The commencing dose is from five to ten minims. W.

EXTRACTUM IPECACUANHÆ FLUIDUM. *U. S. Fluid Extract of Ipecacuanha.*

"Take of Ipecacuanha, in fine powder, *sixteen troyounces;* Acetic Acid *a fluidounce;* Alcohol, Water, each, *a sufficient quantity*. Moisten the Ipecacuanha with six fluidounces of Alcohol, introduce it into a conical percolator, press it firmly, and pour Alcohol upon it until three pints of tincture have slowly passed, or until the Ipecacuanha is exhausted. Distil off the alcohol from the tincture, by means of a water-bath, until a syrupy liquid is left. Mix this with the Acetic Acid and ten fluidounces of Water, boil the mixture gently until it is reduced to half a pint, and the resinous matter has separated. Filter the liquid when cold, and add sufficient Water, through the filter, to make the filtered liquid measure half a pint. Lastly, mix this with half a pint of Alcohol." *U. S.*

A strong tincture is first obtained with officinal alcohol, from which the spirit is afterwards distilled off; the object in using this menstruum being to obtain the active principle of the root, without the gum and starch which give to its liquid preparations a tendency to decomposition. To separate the resinous matter water is then added, together with acetic acid to give stability to the alkaloid during the subsequent boiling. When this is accomplished, the liquid is filtered and diluted with water, and sufficient alcohol to preserve it. A formula for this fluid extract was originally proposed by Mr. Laidley, of Richmond, Va., but was afterwards modified. The addition of acetic acid was suggested by Prof. Procter.

The fluid extract is a thin, dark reddish-brown transparent liquid, of a bitterish slightly acrid taste, but without the nauseous flavour of the root. A fluidounce of it represents an ounce of the root, and the emetic dose would therefore be from fifteen to thirty minims. It is a convenient preparation for adding to expectorant and diaphoretic mixtures, and is used officinally in preparing the syrup of ipecacuanha.

Off. Prep. Syrupus Ipecacuanhæ, *U. S.* W.

EXTRACTUM LUPULINÆ FLUIDUM. *U. S. Fluid Extract of Lupulin.*

"Take of Lupulin *sixteen troyounces;* Stronger Alcohol *a sufficient quantity*. Introduce the Lupulin into a percolator, press it firmly, and, having covered it with a piece of muslin, pour upon it Stronger Alcohol very gradually until twelve fluidounces of tincture have passed. Set this aside in a close vessel, and continue the percolation until twenty fluidounces more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to four fluidounces, and mix it with the reserved tincture." *U. S*

This is a concentrated tincture of lupulin, containing the virtues of an ounce of lupulin in a fluidounce. The dose is ten or fifteen minims, which may be conveniently given mixed with syrup of gum arabic, afterwards diluted with water. W.

EXTRACTUM OPII LIQUIDUM. *Br.* *Liquid Extract of Opium.*

"Take of Extract of Opium *one ounce* [avoirdupois]; Distilled Water *seventeen fluidounces* [Imperial measure]; Rectified Spirit *three fluidounces* [Imp. meas.]. Digest the Extract of Opium in the Water for an hour, stirring frequently; filter, and add the Spirit. The product should measure one pint [Imp. meas.]." *Br.*

This is a good preparation, one which has long been needed, and in the absence of which from the Pharmacopœias empirical preparations have obtained a certain vogue. It is well known that in opium there are principles, soluble in alcohol but not in water, which often produce various disagreeable effects, not experienced from the watery extract. What was wanted was a liquid preparation meeting this demand. All that was required was to make an aqueous solution of the watery extract, and to add something to preserve it. The British Pharmacopœia uses alcohol for the purpose, in such proportion that an Imperial pint of the liquid shall contain three fluidounces of the spirit, or between one-sixth and one-seventh by measure. But this amount of alcohol, according to Mr. Squire, is insufficient for its preservation, and should be doubled. A preparation similar to the British was made some years since by Mr. Eugene Dupuy of New York, an account of which is given in a note to Opium in *Part I.* of this work (page 630). In the new *Deodorized Tincture of Opium* of the U. S. Pharmacopœia, the advantages of the preparation have, we think, been still better secured. (See *Tinctura Opii Deodorata.*) The dose of the liquid extract, equivalent to a grain of opium, would be about 10 minims. W.

EXTRACTUM PAREIRÆ LIQUIDUM. *Br.* *Liquid Extract of Pareira.*

"Take of Pareira, in coarse powder, *one pound* [avoirdupois]; Boiling Distilled Water *one gallon* [Imperial measure], or *a sufficiency.* Macerate the Pareira in a pint [Imp. meas.] of the Water for twenty-four hours, then pack in a percolator, and add Distilled Water until the Pareira is exhausted. Evaporate the liquor by a water-bath to thirteen fluidounces, and, when it is cold, add the Spirit, and filter through paper." *Br.*

This is a concentrated infusion, preserved by adding somewhat less than one-fourth of its measure of alcohol, and is said by those who have used it to have all the virtues of the root. The fluid extract would probably be still more efficient if made with diluted alcohol. The dose is one or two fluidrachms. W.

EXTRACTUM PRUNI VIRGINIANÆ FLUIDUM. *U.S.* *Fluid Extract of Wild-cherry Bark.*

"Take of Wild-cherry Bark, in fine powder, *sixteen troyounces;* Sweet Almond *two troyounces;* Sugar, in coarse powder, *twenty-four troyounces;* Alcohol, Water, each, *a sufficient quantity.* Introduce the Bark, previously mixed with four fluidounces of Alcohol, into a cylindrical percolator, press it firmly, and gradually pour Alcohol upon it until three pints of tincture have slowly passed. From this distil off two pints and a half of alcohol, and, having mixed the residue with a pint of Water, evaporate, by means of a water-bath, to half a pint.

"Beat the Almond into a paste, and rub this with successive portions of Water until, after straining through a coarse sieve or cloth, nearly all the substance of the Almond has been converted into an emulsion, and twelve fluid ounces of liquid have been obtained. Mix this with the liquid first obtained, in a suitable bottle, and, having closely stopped it, agitate occasionally during

twenty-four hours. Then express quickly and strongly through a cloth; and, if the expressed liquid measure less than eighteen fluidounces, add Water to the residue, and again express until that quantity is obtained. Filter the expressed liquid through cotton flannel, in a covered funnel, into a bottle containing the Sugar. Shake the bottle occasionally during the process until the Sugar is dissolved, and continue the filtration until the syrupy liquid measures two pints. Lastly, mix the whole thoroughly together." *U. S.*

This is an ingenious and effectual method of obtaining the virtues of wild-cherry bark in a concentrated liquid form, adopted from a process originally devised and published by Prof. Procter. For various reasons it is expedient to use alcohol as the menstruum for extracting the soluble principles of the bark; the chief reasons being that substances are thus left behind, which if extracted would dispose the preparation to spontaneous change, and that less heat, or a shorter continuance of it, is required in the concentration than if water were the solvent. But by the use of alcohol we prevent those reactions which, by the production of volatile oil and hydrocyanic acid, give the medicine its peculiar value; and the addition of water to the tincture obtained, though in connection with the bark itself it would give rise to the requisite reactions, fails to produce them because the emulsin of the bark, which is essential to the result, is not only not extracted by the alcohol, but is rendered inert by it. It is through the agency of this principle that the amygdalin of the bark reacts with water so as to generate volatile oil and hydrocyanic acid. The alcohol extracts the amygdalin but not the emulsin, nor can the latter principle be now procured from the bark, because it has been destroyed by the alcohol. If, therefore, we wish to obtain the characteristic remedial principles of the bark, such as they exist in the infusion, we must seek for emulsin from another source; and the most convenient is sweet almond. Hence the direction to obtain an emulsion from almonds, which contain emulsin largely. But, if added to the alcoholic liquid first obtained, it would be wholly inoperative, and indeed would be rendered inert for future action. It is, therefore, necessary to separate all the alcohol from that liquid, and replace it with enough water to hold the amygdalin in solution. This is done by first distilling off two and a half of the three pints of alcohol, then adding water, and lastly evaporating all the remainder. This is an essential step of the operation, and success need not be expected unless the alcohol is got rid of. We now have an aqueous solution of amygdalin and whatever other bitter principles the bark may contain; and, when the almond emulsion is added, all the conditions exist requisite to the generation of the oil of bitter almonds with hydrocyanic acid. Nothing now remains but to allow full time for the requisite reaction, then to strain the liquid, adjust the proportion of water necessary to give the desired measure of fluid extract, and add enough sugar to preserve it. Heat is contraindicated in the latter part of the process, as it must interfere with the action of the emulsin, and would certainly drive off a portion of the active volatile principles. Hence, all the requisite concentration must be effected before the almond emulsion is added. If properly made, the fluid extract is a clear syrupy liquid, of a light sherry-wine colour, having strongly the peculiar bitter taste and hydrocyanic acid flavour of the infusion, and capable of dilution to any extent with water, without becoming turbid. As two pints of fluid extract are produced, and the quantity of bark used is sixteen troyounces, it follows that an ounce of the bark is represented by two fluidounces of the fluid extract, the dose of which, therefore, is from one to two fluidrachms. W.

EXTRACTUM RHEI FLUIDUM. *U. S. Fluid Extract of Rhubarb.*

"Take of Rhubarb, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *eight troyounces;* Alcohol *a pint;* Diluted Alcohol *a sufficient quantity.* Moisten the Rhubarb with four fluidounces of the Alcohol, introduce it into a conical percolator, press it gently, and pour upon it the remainder of

the Alcohol. When the liquid has disappeared from the surface, gradually pour on Diluted Alcohol until a pint of tincture has passed. Set this aside in a warm place until reduced by spontaneous evaporation to six fluidounces, and continue the percolation until two pints more of tincture have been obtained. Evaporate this by a gentle heat to six fluidounces; then add the Sugar, and, when this is dissolved, the reserved tincture, and continue the heat until the whole is reduced to the measure of a pint." *U. S.*

The fluid extract of 1850 contained the aromatic oils of fennel and anise, which have been omitted in the new formula, probably for the good reason that they might not always be wanted, and that, should these or any similar oils be desired by any one, they might be readily added. In consequence of the use, in the former process, of diluted alcohol as a menstruum, much of the gummy and other principles soluble in water were extracted, rendering the resulting fluid extract inconveniently thick. Hence, in the arrangement of the present formula, alcohol was substituted; but, unfortunately, care was not taken sufficiently to get rid of this liquid; and the consequence has been that, though the extract when freshly prepared is sufficiently liquid, yet it soon begins to deposit saccharine matter, and in the end becomes so loaded with granular sugar as to be unfit for use. To obviate this result, Prof. Procter proposes to modify the process by allowing the first tincture to be reduced by spontaneous evaporation to *five* instead of six fluidounces, and by evaporating the second tincture made with diluted alcohol only to *eight* instead of six fluidounces; thus diminishing the proportion of alcohol and increasing that of water. (*Proceed. of the Amer. Pharm. Assoc.*, 1863, p. 239.) At best, however, the preparation is inconveniently thick, though excellent in other respects, having the flavour of the root in perfection. Its colour is a deep reddish-brown, and even in dilution, as we have seen it, does not exhibit the yellow hue which might have been expected. This fluid extract may be used directly for obtaining the effects of rhubarb, but it is probably more employed in the preparation of the syrup. A fluidrachm of it should contain the virtues of a drachm of the root; and the dose, therefore, for an adult may be twenty or thirty minims as a purgative, and from five to ten minims as a laxative. W.

EXTRACTUM SARSAPARILLÆ FLUIDUM. *U.S.* EXTRACTUM SARSÆ LIQUIDUM. *Br.* *Fluid Extract of Sarsaparilla.*

"Take of Sarsaparilla, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *ten troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Sarsaparilla with half a pint of Diluted Alcohol, pack it firmly in a cylindrical percolator, and gradually pour upon it Diluted Alcohol until four pints of tincture have been obtained. Evaporate this, by means of a water-bath, to a pint; then add the Sugar, and continue the evaporation until the liquid is reduced to the measure of a pint, and strain while hot." *U. S.*

"Take of Jamaica Sarsaparilla, not split, *one pound* [avoirdupois]; Distilled Water, at 160°, *fourteen pints* [Imperial measure]; Rectified Spirit *one fluidounce.* Macerate the Sarsaparilla in one-half of the Water for six hours, and decant the liquor. Digest the residue in the remainder of the Water for the same time, express, and filter the mixed liquors, and evaporate them by a water-bath to seven fluidounces, or until the sp. gr. of the liquid is 1·13. When cold, add the Spirit. The sp. gr. should be 1·095." *Br.*

Of these two processes, that of the U. S. Pharmacopœia, except in respect to the high price of alcohol, is greatly preferable; and this objection will be in great measure obviated by recovering the alcohol, which can be done by using a distillatory apparatus in the evaporation. There can be no doubt that Sarsaparilla is more thoroughly exhausted when submitted, in the state of powder, to percolation with diluted alcohol, than it can be by maceration and subsequent digestion of the whole root in water, even though continued for twelve hours; the

subsequent evaporation of the tincture requires less heat than that of the infusion, and thus less danger of injury is incurred from this cause; and the sugar is preferable as a preservative to alcohol, even admitting, what is scarcely probable, that the quantity of spirit directed in the Br. formula is sufficient to prevent decomposition, especially in our hot summer weather. There is some difficulty in properly mixing the powder with the menstruum, as it is apt to agglutinate in lumps; but this can be obviated by suitable manipulation, and a uniformly moistened mass obtained. If care be taken to have the powder of the due degree of fineness, to moisten it uniformly, and to pack it well in the percolator, it will be exhausted by a smaller amount of diluted alcohol than that indicated in the U. S. formula. The introduction of a simple fluid extract of sarsaparilla into our Pharmacopœia was judicious; as it enables the physician to associate this medicine with others at his pleasure, and in such proportions as he may deem expedient. He may rely upon the efficiency of the preparation, if made with sufficient care and skill, and from good parcels of the root. The U. S. fluid extract is a somewhat thickish, turbid, but sufficiently mobile liquid, of a dark reddish-brown colour, and of a sweet and a slightly though persistently acrid taste. The dose is from thirty to sixty minims, equivalent to the same number of grains of sarsaparilla in substance. W.

EXTRACTUM SARSAPARILLÆ FLUIDUM COMPOSITUM. *U. S.* EXTRACTUM SARSAPARILLÆ FLUIDUM. *U.S.* 1850. *Compound Fluid Extract of Sarsaparilla.*

"Take of Sarsaparilla, in moderately fine powder, *sixteen troyounces;* Liquorice Root, in moderately fine powder, Bark of Sassafras Root, in moderately fine powder, each, *two troyounces;* Mezereon, in moderately fine powder, *three hundred and sixty grains;* Sugar *twelve troyounces;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with ten fluidounces of Diluted Alcohol, pack it firmly in a cylindrical percolator, and gradually pour upon it Diluted Alcohol until four pints of tincture have been obtained. Evaporate this, by means of a water-bath, to twelve fluidounces; then add the Sugar, and continue the evaporation until the liquid is reduced to the measure of eighteen fluidounces, and strain while hot." *U. S.*

This is the Extractum Sarsaparillæ Fluidum of the U. S. Pharmacopœia of 1850, now necessarily entitled "Compositum," to distinguish it from the simple fluid extract newly introduced. The present is a much neater formula than the old one by maceration, but more liable to miscarry unless skilfully executed. Everything depends upon having the several ingredients equably powdered, mixing them well and duly moistening them, and then packing them properly in the percolator. The moistening of the mixed powders is more easily effected, as they are less disposed to form lumps than the sarsaparilla powder alone. The preparation is intended to represent, in a concentrated state, the compound decoction of sarsaparilla, having all its ingredients with the exception of the guaiacum wood, which probably adds little to the efficacy of the decoction. It was originally proposed by Wm. Hodgson, jun. (*Journ. of the Philad. Col. of Pharm.*, ii. 285); and the officinal process differs from his mainly in the omission of the guaiacum wood, the resin of which, separating during the evaporation, somewhat embarrassed the process, without adding to the virtues of the extract. The dose is from thirty minims to a fluidrachm, equivalent to half a drachm or a drachm of the root, three or four times a day. W.

EXTRACTUM SENNÆ FLUIDUM. *U. S. Fluid Extract of Senna.*

"Take of Senna, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *eight troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Senna with six fluidounces of Diluted Alcohol, introduce it into a conical percolator, press it firmly, and gradually pour upon it Diluted Alcohol until a

pint of tincture has passed. Set this aside in a warm place until reduced by spontaneous evaporation to half a pint. Continue the percolation until two pints more of tincture have been obtained. To this add the Sugar, and, having evaporated it, by means of a water-bath, to half a pint, mix it with the reserved tincture, and strain." *U. S.*

The present officinal fluid extract of senna differs materially from that of the Pharmacopœia of 1850, containing neither the oil of fennel before used as a flavouring material, nor the Hoffmann's anodyne which was added for its preservative influence. It was deemed better to leave to the prescriber the choice of the volatile oil; and to depend for the preservation of the fluid extract upon the sugar and what might remain of the alcohol after the evaporation. Another alteration, undoubtedly judicious, was to set aside the first strong tincture for spontaneous evaporation, thus avoiding the application of heat to the greater portion of the active matter. The fluid extract is a dark, reddish-brown, thickish and somewhat turbid liquid, with a strong flavour of senna. The dose is from one to four fluidrachms for an adult. In consequence of its griping tendency it should be mixed with one of the volatile oils, as of fennel, anise, or caraway, in the proportion of about two minims to the fluidounce; and is well adapted for exhibition with saline cathartics, such as Epsom salt or cream of tartar, which also obviate its griping. In this case not more than one-half of the full dose of the fluid extract should be given at once.

Off. Prep. Extractum Spigeliæ et Sennæ Fluidum, *U. S.* W.

EXTRACTUM SERPENTARIÆ FLUIDUM. *U. S. Fluid Extract of Serpentaria.*

"Take of Serpentaria, in moderately fine powder, *sixteen troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Serpentaria with five fluidounces of Diluted Alcohol, introduce it into a conical percolator, press it firmly, and gradually pour upon it Diluted Alcohol until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints and a half more of tincture have been obtained. Evaporate this, at a temperature not exceeding 150°, until it is reduced to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

This is among the new officinal fluid extracts, and, though simply a concentrated tincture, is a good preparation, containing the virtues of the root within a small bulk. The fluid extract of serpentaria originated with Mr. J. C. Savery, whose formula was published in the eleventh edition of the U. S. Dispensatory (*page* 713). It was afterwards modified by Mr. A. B. Taylor (*Am. Journ. of Pharm.*, xxv. 206); and the formula ultimately adopted was that contained in Prof. Procter's Report (A. D. 1859). The fluid extract is thin, reddish-brown, and transparent, with the peculiar bitterness of the root in perfection, but its odour less obviously. A fluidounce of it is equivalent to a troyounce of the powder, and the dose is twenty or thirty minims, to be frequently repeated. W.

EXTRACTUM SPIGELIÆ ET SENNÆ FLUIDUM. *U. S. Fluid Extract of Spigelia and Senna.*

"Take of Fluid Extract of Spigelia *ten fluidounces;* Fluid Extract of Senna *six fluidounces;* Carbonate of Potassa *half a troyounce;* Oil of Anise, Oil of Caraway, each, *twenty minims.* Mix the Fluid Extracts, and dissolve in the mixture the Carbonate of Potassa and the Oils, previously rubbed together." *U. S.*

This fluid extract was formerly made from powdered pinkroot and senna by percolation and concentration; but it is now more conveniently prepared by simply mixing the two fluid extracts. It combines the cathartic property of senna with the anthelmintic virtues of pinkroot, and is a very good vermifuge, being generally acceptable to the stomach, and, what is of no little importance in such medi-

cines, not offensive to the taste. It has been in use in Philadelphia for several years, and with satisfactory results. The use of the carbonate of potassa is to enable any resinous matter which may be deposited to be dissolved, and also to counteract the griping property of the senna. The dose is from two fluidrachms to half a fluidounce for an adult, from thirty minims to a fluidrachm for a child two years old. W.

EXTRACTUM SPIGELIÆ FLUIDUM. *U. S.* *Fluid Extract of Spigelia.*

"Take of Spigelia, in fine powder, *sixteen troyounces;* Sugar, in coarse powder, *eight troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Spigelia with six fluidounces of Diluted Alcohol, introduce it into a conical percolator, press it firmly, and gradually pour upon it Diluted Alcohol until a pint of tincture has passed. Set this aside in a warm place until it is reduced by spontaneous evaporation to half a pint. Continue the percolation until two pints more of tincture have been obtained. To this add the Sugar, and, having evaporated it, by means of a water-bath, to half a pint, mix it with the reserved tincture, and strain." *U. S.*

This process is the same as that for the fluid extract of senna, and yields a dark-brown, translucent, syrupy liquid, with the flavour of the root. A fluidounce of it represents the virtues of a troyounce of spigelia, and the dose of it is one or two fluidrachms for an adult, from ten to twenty minims for a child two or three years old, to be repeated morning and evening for three or four days, and then followed by a brisk cathartic. It is, however, most used in connection with the fluid extract of senna.

Off. Prep. Extractum Spigeliæ et Sennæ Fluidum, *U. S.* W.

EXTRACTUM TARAXACI FLUIDUM. *U. S.* *Fluid Extract of Dandelion.*

"Take of Dandelion, in moderately fine powder, *sixteen troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Dandelion with four fluidounces of Diluted Alcohol, introduce it into a conical percolator, press it firmly, and gradually pour upon it Diluted Alcohol until half a pint of tincture has passed. Set this aside, and continue the percolation until two pints and a half more of tincture have been obtained. Evaporate this, at a temperature not exceeding 120°, until it is reduced to half a pint, mix it with the reserved tincture, and filter through paper." *U. S.*

This is a concentrated tincture of dandelion, containing only about one-fourth by measure of officinal alcohol, and therefore weak in alcoholic strength, yet strong enough to keep well. The formula is based on sound principles, and the fluid extract, if well prepared from the root in an efficient state, may be relied on for producing the effects of the medicine on the system. It is mobile, of a dark reddish-brown colour, translucent, and a sweet not disagreeable taste; and may be given in the dose of one or two fluidrachms three times a day. W.

EXTRACTUM UVÆ URSI FLUIDUM. *U. S.* *Fluid Extract of Uva Ursi.*

"Take of Uva Ursi, in moderately fine powder, *sixteen troyounces;* Sugar, in coarse powder, *eight troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the Uva Ursi with six fluidounces of Diluted Alcohol, introduce it into a conical glass percolator, press it firmly, and gradually pour upon it Diluted Alcohol until half a pint of tincture has passed. Set this aside, and continue the percolation until two pints and a half more of tincture have been obtained. Evaporate this, by means of a water-bath, to four fluidounces, and, having dissolved the Sugar in it while hot, mix it with the reserved tincture, and strain. Lastly, evaporate the whole by a gentle heat until it is reduced to a pint." *U. S.*

Like the preceding, this is a concentrated tincture, in which the aid of sugar is called in apparently to contribute to its preservation, though scarcely required for the purpose, as it contains nearly 20 per cent. of officinal alcohol. The saccharine constituent, however, unless it may granulate, is useful by improving the flavour of the medicine. It is a thickish, syrupy, dark-brown, somewhat translucent liquid, of a sweet, bitterish, astringent, but not very disagreeable taste. The dose of this preparation is from thirty minims to a fluidrachm three times a day. W.

EXTRACTUM VALERIANÆ FLUIDUM. *U.S. Fluid Extract of Valerian.*

"Take of Valerian, in fine powder, *sixteen troyounces;* Alcohol *a sufficient quantity.* Moisten the Valerian with six fluidounces of Alcohol, introduce it into a conical percolator, press it firmly, and gradually pour Alcohol upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until two pints more of tincture have been obtained. Evaporate this to four fluidounces at a temperature not exceeding 120°, mix it with the reserved tincture, and filter through paper." *U.S.*

This is another concentrated tincture, strong both in alcohol and the virtues of valerian. It is probable that all or nearly all the volatile ingredients of the root are extracted by the twelve fluidounces of alcohol which first pass, and which, not being exposed to evaporation, lose none of the volatile oil and acid which they have dissolved; while the soluble matter subsequently extracted, consisting chiefly of the fixed principles, will not be dissipated by the concentration ordered; and, as this is directed to be made at a heat not exceeding 120°, even the volatile principles which may have escaped the first alcohol, will scarcely be driven off to an appreciable amount. The fluid extract may, therefore, be considered as fully representing the virtues of the root. The formula is, with some modification, that of Prof. Grahame, of Baltimore, published in the *Am. Journ. of Pharm.* (xxxi. 379). The preparation is a dark soot-coloured liquid, transparent in thin layers, with the smell and taste of valerian. The dose is about a fluidrachm. W.

EXTRACTUM VERATRI VIRIDIS FLUIDUM. *U.S. Fluid Extract of American Hellebore.*

"Take of American Hellebore, in fine powder, *sixteen troyounces;* Alcohol *a sufficient quantity.* Moisten the Hellebore with six fluidounces of Alcohol, introduce it into a cylindrical percolator, press it firmly, and gradually pour Alcohol upon it until half a pint of tincture has passed. Set this aside, and continue the percolation until two pints and a half more of tincture have been obtained. Evaporate this, by means of a water-bath, at a temperature not exceeding 150°, to half a pint, mix it with the reserved tincture, and filter through paper." *U.S.*

It may be doubted whether this fluid extract is among those demanded by the wants of the profession. We have already a tincture, which, supposing none of the virtues of the medicine to be lost in preparing the fluid extract, will be at least half as strong, and at all events is quite strong enough. It is true that the proportion of alcohol is somewhat less in the fluid extract; but, in so powerful a preparation, this is of little consequence. The tincture itself purports to be saturated; and, though it is probable that, by the concentration of the alcoholic solution, more of the active matter is held by it in the same measure of alcohol than by the tincture; yet a portion of this active matter may be deposited during the evaporation; and, as the deposit is separated by the filtration, no accurate ground of calculation is left as to the real strength of the fluid extract. It may be but little stronger than the tincture, or may possibly be of double the strength; a point which can be determined only by analysis, or physiological

experiment, to ascertain how much, if any, of the active matter may be contained in the separated deposit. In the mean time, it would be injudicious to prescribe more of it, as a commencing dose, than from two to four minims. W.

EXTRACTUM ZINGIBERIS FLUIDUM. *U. S.* *Fluid Extract of Ginger.*

"Take of Ginger, in fine powder, *sixteen troyounces;* Alcohol *a sufficient quantity.* Moisten the Ginger with four fluidounces of Alcohol, introduce it into a cylindrical percolator, press it firmly, and gradually pour Alcohol upon it until twelve fluidounces of tincture have passed. Set this aside, and continue the percolation until twenty fluidounces more of tincture have been obtained. Evaporate this to four fluidounces, mix it with the reserved tincture, and filter through paper." *U. S.*

The fluid extract of ginger is a highly concentrated alcoholic solution of the active principles of ginger. It is transparent, and of a reddish-brown colour; and each minim represents a grain of the root. The dose, therefore, is from ten to twenty minims, or double the number of drops. W.

FEL BOVINUM.

Preparation of Ox-gall.

In the British Pharmacopœia crude Ox Bile is placed in the *Appendix*, as one of the substances used in preparing medicines; and, in the second part of the work, the following process is given for its purification.

FEL BOVINUM PURIFICATUM. *Br.* *Purified Ox Bile.*

"Take of Fresh Ox Bile *one pint* [Imperial measure]; Rectified Spirit *two pints* [Imp. meas.]. Mix the Bile and the Spirit by agitation in a bottle, and set aside for twelve hours until the sediment subsides. Decant the clear solution, and evaporate in a porcelain capsule on a water-bath, until the residue acquires the consistence of a vegetable extract." *Br.*

The properties and uses of Ox Bile are fully treated of in *Part III.* of this work (see *Ox-gall*). The purified bile is sometimes used in cases of debility of the alimentary canal in which the due proportion of bile is wanting. The dose is from two to five grains, and is best given in pill, as there is some chance that it may then pass unchanged into the bowels, where its effects are wanted. W.

FERRUM.

Preparations of Iron.

In accordance with the U. S. Pharmacopœia, we arrange all the preparations of iron under the several heads to which, by the character of the preparation, they appear to belong; the pills, for example, with the Pilulæ or Pills, and the solutions with the Liquores or Solutions. Formerly some of them were distributed according to this plan of arrangement, others were treated of among the preparations of iron. The rule is now made uniform. The preparations of iron considered elsewhere than in the present place are *Plaster of Iron*, with the Emplastra or *Plasters;* *Solutions of Citrate, Iodide, Nitrate, Perchloride, Persulphate, Subsulphate*, and *Tersulphate of Iron*, with the Liquores or *Solutions;* *Pills of Carbonate of Iron, Compound Pills of Iron*, and *Pills of Iodide of Iron*, with the Pilulæ or *Pills;* *Syrups of Iodide* and *Phosphate of Iron* with the Syrupi or *Syrups;* *Tincture of Chloride of Iron* with the Tincturæ or *Tinctures;* *Troches of Carbonate of Iron*, with the Trochisci or *Troches;* and the *Wine of Iron* with the Vina or *Wines*. The preparations contained in the old Pharmacopœias, and omitted in the present, are the *Ace-*

tated Tincture of Iron, Dub., the *Sulphuret of Iron*, Ed., Dub., the *Valerianate of Iron*, Dub., the *Ammoniated Iron*, U. S., Lond.; and the *Tincture of Ammonio-chloride of Iron*, Lond.

FERRI ARSENIAS. *Br.* *Arseniate of Iron.*

"Take of Sulphate of Iron *nine ounces* [avoirdupois]; Arseniate of Soda, dried at 300°, *four ounces* [avoird.]; Acetate of Soda *three ounces* [avoird.]; Boiling Distilled Water *a sufficiency*. Dissolve the Arseniate and Acetate of Soda in *two pints* [Imperial measure], and the Sulphate of Iron in *three pints* [Imp. meas.] of the Water, mix the two solutions, collect the white precipitate which forms, on a calico filter, and wash until the washings cease to be affected by a dilute solution of chloride of barium. Squeeze the washed precipitate between folds of strong linen in a screw press, and dry it on porous bricks, in a warm chamber whose temperature shall not exceed 100°." *Br.*

This is a new officinal of the British Pharmacopœia, which as yet is the only one that has adopted it. Of the salts used in the process, omitting their water of crystallization, the sulphate of iron consists of one eq. of protoxide of iron and one of sulphuric acid, the arseniate of soda of two eqs. of soda and one eq. of arsenic acid, and the acetate of soda of one eq. of base and one of acid; while the salt to be obtained consists of three eqs. of protoxide of iron and one of arsenic acid. The reactions which result in the production of the last-mentioned salt take place between three eqs. of sulphate of iron and one eq. of each of the other salts. The three eqs. of protoxide of iron of the sulphate unite with the one eq. of arsenic acid of the arseniate to form one eq. of arseniate of iron, which is deposited; while the three eqs. of sulphuric acid, thus liberated, combine with the two liberated eqs. of soda of the arseniate of soda, and one eq. of soda of the acetate, to make three eqs. of sulphate of soda, which, with the separated acetic acid, remain in solution. The quantities of the several salts are very nearly in due equivalent proportion; the arseniate and acetate of soda, however, being very slightly in excess.

Arseniate of iron is white when first formed, but quickly becomes green on exposure to the air. It is an amorphous powder, without smell or taste, insoluble in water, but readily dissolved by muriatic acid. It consists of three eqs. of protoxide of iron and one of arsenic acid ($3FeO,AsO_5$), but, like other salts of protoxide of iron, absorbs oxygen, and probably, therefore, contains an indefinite proportion of sesquioxide of iron. The British Pharmacopœia gives the following characters of the salt. Its solution in muriatic acid causes a copious light-blue precipitate with ferridcyanide of potassium, and a still more abundant one, of a deeper colour, with ferrocyanide of potassium. A small quantity, boiled with an excess of soda, and filtered, gives, when exactly neutralized by nitric acid, a brick-red precipitate on the addition of solution of nitrate of silver. The former test proves the presence both of protoxide and sesquioxide of iron, the latter of arsenic acid. The solution in muriatic acid, when diluted, gives no precipitate with chloride of barium, showing the absence of any sulphate. "Twenty grains dissolved in an excess of hydrochloric acid diluted with water continue to give a blue precipitate with ferridcyanide of potassium, until at least 17 measures of the *volumetric solution of bichromate of potash* have been added." *Br.* This test proves that there is a due proportion of the protoxide of iron present; for the bichromate of potassa oxidizes the protoxide, and, until this is wholly converted into sesquioxide, a blue precipitate continues to be produced, ceasing, however, when the conversion is complete.

Medical Properties. The arseniate of iron is said to unite the virtues of the two metals which enter into its composition; but the quantity of iron in any permissible dose is so small as to be nearly or quite insignificant; and the activity of the medicine is in fact due to the arsenic alone. The complaints in which it has been found efficient are those in which arsenic in other forms has

proved to be a most valuable remedy; and, judging from our own observation, there is no one of them in which the common solution of arsenite of potassa will not produce all the effects that can be obtained from the arsenical preparations with which this ought undoubtedly to be ranked rather than with the chalybeates. Should the coexistence of an anemic state of the system with any disease requiring the use of arsenic, indicate the joint use of iron, it would be unsafe to depend on the arseniate of iron alone. This remedy is peculiarly useful in chronic affections of the skin, especially those of a scaly character, as lepra, psoriasis, and the advanced stage of eczema and impetigo. It is useful also in lupus; and, mixed with twelve times its weight of simple cerate, may be employed externally in cancerous ulcers, though much caution is requisite. The dose is from the eighth to the tenth of a grain, of which about one-half only is protoxide of iron.* It may be given in pill, three times a day. W.

FERRI CARBONAS SACCHARATA. *Br. Saccharated Carbonate of Iron.*

"Take of Sulphate of Iron *two ounces* [avoirdupois]; Carbonate of Soda *two ounces and a half* [avoird.]; Boiling Distilled Water *two gallons* [Imperial measure]; Refined Sugar *one ounce* [avoird.]. Dissolve the Sulphate of Iron and the Carbonate of Soda each in half a gallon [Imp. meas.] of the Water, and mix the two solutions with brisk stirring in a deep cylindrical vessel, which is then to be covered as accurately as possible. Set the mixture by for twenty-four hours, and from the precipitate which has subsided separate the supernatant solution by a siphon. Pour on the remainder of the water, stir well, and, after subsidence, again remove the clear solution. Collect the resulting carbonate on a calico filter, and, having first subjected it to expression, rub it with the Sugar in a porcelain mortar. Finally dry the mixture at a temperature not exceeding 212°." *Br.*

When solutions of sulphate of iron and carbonate of soda are mixed together, there are formed, by double decomposition, sulphate of soda which remains in solution, and carbonate of protoxide of iron which falls as a pale-blue precipitate. This precipitate begins immediately to alter in nature by the absorption of oxygen, and, if washed and dried in the ordinary way, becomes sesquioxide of iron, associated with a small quantity of the carbonate of the protoxide, which has escaped change; in other words, it is converted into the subcarbonate of iron of the U. S. Pharmacopœia. (See *Ferri Subcarbonas.*) As the preparations of iron containing the protoxide are most esteemed, the change which this precipitate undergoes was always matter of regret, and various attempts were made to prevent it. Now saccharine matter has been ascertained to possess the required property; and, in the preparation under consideration, it is used to prevent the protoxide of iron of the carbonate as first precipitated from passing into sesquioxide, with loss of carbonic acid.

Dr. Becker, a German physician, was the first to suggest the use of saccharine matter as a means of protection against the absorption of oxygen; and the idea was carried out by Klauer, a German chemist, who first made the saccharine carbonate of iron. The use of boiling distilled water in the process is to avoid the

* The statement as to the uses and dose of this arseniate is taken from the British authorities, as we have had no experience with the remedy; but, if the minuteness of the dose stated is rendered necessary by the great activity of the preparation, the explanation given, at page 28, of the mode in which hydrated sesquioxide of iron acts as an antidote to arsenious acid must be modified; for it is there represented that the hydrated sesquioxide acts by giving up a part of its oxygen to the arsenious acid, forming the arseniate of the protoxide of arsenic, which is said to be inert. It is more probable that it is the sesquiarseniate of the sesquioxide of iron that is formed in cases of poisoning ($2Fe_2O_3.3AsO_3$); the arsenic acid, when formed at the expense of a portion of the sesquioxide, combining with another portion not decomposed.—*Note to the twelfth edition.*

action of the air contained in unboiled water. The washed precipitate is pressed so as to free it from water as far as possible, and then incorporated with the sugar in fine powder. The mode of treating the precipitate unnecessarily exposes it to the action of the air; and the late London method of incorporating it with the sugar immediately after washing was on this account preferable. The final drying heat should not exceed 130°. The protection from oxidation, however, is more complete, when both the materials and product of the process are maintained constantly in contact with saccharine matter, by using weak syrup both for dissolving the salts and washing the precipitate, after the improved method of Vallet, of Paris. This improved method of proceeding is adopted for forming the U. S. pills of carbonate of iron, or Vallet's ferruginous pills. (See *Pilulæ Ferri Carbonatis, U. S.*)

Properties. Saccharine carbonate of iron is in small coherent lumps, of a grayish-brown colour, permanent in the air, having a sweet, styptic taste, and wholly and readily soluble in muriatic acid with brisk effervescence. According to the British Pharmacopœia, it is a "carbonate of iron (FeO,CO_2), mixed with peroxide of iron and sugar, and forming 57 per cent. of the mixture." The presence of sesquioxide of iron is a defect, which is avoided in Vallet's ferruginous pills.

Its solution in dilute muriatic acid is but slightly affected by ferrocyanide of potassium, showing the presence of the sesquioxide of iron in only small proportion, but yields a copious blue precipitate with the ferridcyanide, proving the abundance of the protoxide. The same solution should give but a very slight precipitate with chloride of barium, evincing that very little sulphate either of iron or soda has escaped the washing process. "Twenty grains dissolved in excess of hydrochloric acid, and diluted with water, continue to give a blue precipitate with ferridcyanide of potassium until at least 33 measures of the *volumetric solution of bichromate of potash* have been added." *Br.* This test determines the quantity of protoxide of iron present, requiring the stated amount of the bichromate to convert it into sesquioxide. It would appear, from the data here given, that the preparation contains 27·72 per cent. of the protoxide.

Medical Properties. This preparation is an excellent chalybeate, possessing the advantages of having nearly all the iron in it in the state of protoxide, and of being readily soluble in acids. Originally introduced into the officinal list by the Edinburgh College, it appeared for the first time in the Dublin and London Pharmacopœias of 1850 and 1851. It is probably more active than the subcarbonate of iron, and must be used in a smaller dose. It is, however, inferior to Vallet's ferruginous mass, in the preparation of which the anti-oxidizing influence of saccharine matter is more fully applied. The dose of the saccharine carbonate of iron is from five to thirty grains, given in the form of pill.

Off. Prep. Pilula Ferri Carbonatis, *Br.* B.

FERRI CHLORIDUM. *U. S. Chloride of Iron. Sesquichloride of Iron. Perchloride of Iron.*

"Take of Iron, in the form of wire and cut in pieces, *two troyounces;* Muriatic Acid *twelve troyounces;* Nitric Acid *a troyounce,* or *a sufficient quantity.* To eight troyounces of the Muriatic Acid, introduced into a two-pint flask, add the Iron, and apply a gentle heat, until the Acid is saturated and effervescence has ceased. Filter the solution, add to it the remainder of the Muriatic Acid, heat the mixture nearly to the boiling point in a four-pint porcelain capsule, and add Nitric Acid in successive portions until red fumes are no longer evolved, and a drop of the liquid ceases to yield a blue precipitate with ferridcyanide of potassium. Transfer the liquid to a smaller capsule, evaporate it by a gentle heat, on a sand-bath, until reduced to eight troyounces and three hundred and sixty grains, and set it aside, covered with glass, for several days, in order that it may form a solid, crystalline mass. Lastly, break this into pieces, and keep the fragments in a well-stopped bottle protected from the light." *U. S.*

This is a new formula of the U. S. Pharmacopœia, adopted with little alteration from that of Wittstein. (*Pract. Pharm. Chem., Darby's Transl.* p. 265.) When iron is heated with muriatic acid, water is decomposed, the hydrogen escapes with effervescence, and the oxygen uniting with the iron forms the protoxide of that metal, which reacts with the muriatic acid to form water and protochloride of iron. This is believed by the author to be the true rationale; though a simpler explanation is usually given, according to which the chlorine of the acid unites directly with the iron, and the hydrogen is set free. The next step of the process is to convert the protochloride into the sesquichloride of iron. This is effected by treating it with muriatic and nitric acids, and heating till red fumes no longer escape. The nitric acid is decomposed into nitric oxide, which, escaping, forms red hyponitric acid fumes by combining with the oxygen of the air, and into oxygen which sesquioxidizes a portion of the iron of the protochloride, thus converting the remainder into sesquichloride, while the sesquioxide produced reacts with the additional muriatic acid to form an additional portion of sesquichloride; or the oxygen of the nitric acid may combine with the hydrogen of the muriatic acid, and thus liberate sufficient chlorine to form a sesquichloride with the iron. The solution is then evaporated, and, on cooling, concretes into a crystalline mass. The relative proportions of iron and the two acids are adjusted very nearly to the production of these results.

Properties. Sesquichloride of iron (Ferri Chloridum, *U. S.*) is in fragments of a crystalline structure, an orange-yellow colour, inodorous, and of a strong chalybeate and styptic taste. It is deliquescent, very soluble in water, and soluble also in alcohol and ether. It consists of two eqs. of iron and three of chlorine (Fe_2Cl_3), with a variable proportion of water according to the crystalline forms it is made to assume, having about 40 per cent. or 12 eqs. when in fine acicular crystals, and only 22 per cent. or 5 eqs. when in the form of larger tables. (*Brande and Taylor.*) Its solution in water gives with ammonia a brown precipitate of sesquioxide of iron, and does not yield a blue one with the ferridcyanide of potassium, proving the absence of protochloride or protoxide of iron.

Internally the sesquichloride of iron is used almost exclusively in the form of tincture; and in reference to its effect and application we refer to the *Tinctura Ferri Chloridi.* Externally it is as generally used in the form of watery solution; and as the British Pharmacopœia has an officinal solution, which it will be necessary to treat of under a special head, we shall postpone a further consideration of the subject till this preparation is treated of. (See *Liquor Ferri Perchloridi.*) It is kept in the solid state, because, when dissolved, it is apt to deposit sesquioxide of iron (oxychloride of iron, *Brurin du Buisson*) in an insoluble condition, whereby an excess of acid is produced, which renders the preparation too irritant for many of the purposes for which it is used. (Squibb, *N. Y. Journ. of Med.*, March, 1860, p. 170.) As a solid, it keeps indefinitely without change. When used, it may be dissolved in water in such proportions as may be required. Six, three, two, and one and a half drachms to a fluidounce of water have been recommended; the stronger solutions being used in the treatment of varices, the weaker for injection into aneurisms, and for application to bleeding surfaces, &c. Mr. J. Z. Lawrence, of England, has used it as a styptic in a semi-deliquesced state, and found it extremely efficient. He keeps it in a bottle, in which it gradually deliquesces; and, while it is in this condition, he applies the thick liquid portion, by means of a brush of spun-glass, to the bleeding surface. He has employed it in arresting hemorrhage after excision of the tonsils, and from the deeper-seated gums. (*Med. Times and Gaz.*, Aug. 1859, p. 219.) Chloride of iron has been employed internally, by Messrs. Jodin and Auprun, of Paris, and with great asserted success, in the treatment of pseudomembranous croup, in quantities varying, according to the severity of the disease and

the age of the patient, from ninety grains to half an ounce, in divided doses, in the twenty-four hours, and continued for three or four days. (*Ann. de Thérap.*, 1861, p. 201.) W.

FERRI CITRAS. *U. S. Citrate of Iron.*

"Take of Solution of Citrate of Iron *a convenient quantity*. Evaporate it to the consistence of syrup, and spread it on plates of glass, so that, on drying, the salt may be obtained in scales." *U. S.*

Citrate of iron, as thus prepared, is in thin transparent pieces, of a beautiful garnet-red colour. It is an uncrystallizable salt, slowly soluble in cold, but readily soluble in boiling water, and possessing a mild chalybeate taste. It probably consists of one eq. of citric acid 165, and one of sesquioxide of iron 80 = 245.

Citrate of iron was introduced to the notice of the profession, in 1831, by M. Béral, of Paris. It is a pleasant chalybeate, and is best given in solution. Prof. Procter finds that a solution of this salt in distilled water, containing 240 grains to the fluidounce, keeps perfectly, and is very convenient for dispensing. It may be given in the dose of ten minims, containing five grains of the salt, several times a day. (See *Liquor Ferri Citratis.*) B.

FERRI ET AMMONIÆ CITRAS. *U. S.*, *Br. Citrate of Iron and Ammonia.*

"Take of Solution of Citrate of Iron *a pint;* Water of Ammonia *six fluidounces*. Mix the Solution of Citrate of Iron with the Water of Ammonia, evaporate the mixture, at a temperature not exceeding 150°, to the consistence of syrup, and spread it on plates of glass, so that, on drying, the salt may be obtained in scales." *U. S.*

"Take of Solution of Persulphate of Iron *eight fluidounces;* Solution of Ammonia *fourteen fluidounces*, or *a sufficiency;* Citric Acid, in crystals, *five ounces* [avoirdupois]; Distilled Water *half a gallon* [Imperial measure]. Add the Persulphate of Iron to two pints [Imp. meas.] of the Distilled Water, and gradually pour the dilute solution into the Solution of Ammonia, stirring well for a few minutes; collect on a calico filter the hydrated peroxide of Iron which precipitates, and wash it with distilled water until the filtrate ceases to become turbid on the addition of chloride of barium. Dissolve the Citric Acid in the remainder of the Water, and digest the solution at a boiling heat on the oxide of iron. Make the liquid neutral by the addition of Solution of Ammonia, and evaporate it to dryness in thin layers, on flat porcelain or glass plates. Remove the dry salt in flakes, and keep it in stoppered bottles." *Br.*

In the U. S. Pharmacopœia, the process consists simply in evaporating a mixture of solution of citrate of iron and water of ammonia. In the British, hydrated sesquioxide of iron is first precipitated from a solution of the tersulphate, then digested at a boiling heat with a solution of citric acid, and lastly neutralized by ammonia. It has, however, been found by Dr. Squibb that a heat above 180° acts injuriously in the preparation of the citrate of iron; and the boiling heat directed in the British Pharmacopœia is, therefore, improper. (*Am. Journ. of Pharm.*, xxvii. 297.) In the U. S. formula the citrate of iron is used already prepared, in the British is prepared in the process. The direction as to the evaporation, at the close of the British process, is not sufficiently explicit. The solution should be concentrated to a syrupy consistence, as ordered in the U. S. formula, before being poured out on porcelain or glass to dry; and it is important that the heat employed in the concentration should not exceed 150°.

Properties, &c. Ammonio-citrate of iron is in garnet-red translucent scales, having a slightly chalybeate taste, and readily and wholly soluble in water, forming a solution of a clear ruby colour. It is much more readily soluble in water than the citrate of iron, described in the last article. It is almost insoluble in alcohol. It is neutral to test paper; and its solution in water, acidulated with

muriatic acid, though not rendered blue by ferridcyanide of potassium, gives a copious blue precipitate with the ferrocyanide, at once proving the absence of protoxide of iron and the presence of the sesquioxide. In heated solution it is decomposed by potassa, soda, and lime-water, which throw down sesquioxide of iron and evolve ammonia; and the alkaline solution from which the iron has been thrown down, if acidulated with muriatic acid in slight excess, does not yield a crystalline deposit, showing that the acid is not the tartaric. When incinerated in the air, it leaves 26·5 per cent. of peroxide of iron. Its precise chemical constitution is not determined; but it probably consists of one eq. of each of its three constituents, besides water ($Fe_2O_3,NH_4O,HO,C_{12}H_5O_{11}+2HO$). (*Br.*) This salt is a pleasant chalybeate. Its ready solubility gives it an advantage over the citrate. The dose is five grains, repeated several times a day, and given in solution. According to Dr. Paris it may be mixed with the carbonated alkalies without decomposition, and given in a state of effervescence with citric acid. B.

FERRI ET AMMONIÆ SULPHAS. *U.S. Sulphate of Iron and Ammonia. Ammonio-ferric Alum.*

"Take of Solution of Tersulphate of Iron *two pints;* Sulphate of Ammonia *four troyounces and a half.* Heat the Solution of Tersulphate of Iron to the boiling point, add the Sulphate of Ammonia, stirring until it is dissolved, and set the liquid aside to crystallize. Wash the crystals quickly with very cold water, wrap them in bibulous paper, and dry them in the open air." *U. S.*

This is an ammonia iron-alum, in which the place of the sesquioxide of aluminium (alumina) is occupied by sesquioxide of iron. It is prepared by heating the solution of tersulphate of iron with sulphate of ammonia until the latter salt is dissolved, and then allowing the solution to cool. The two salts unite to form the sulphate of iron and ammonia, which, being insoluble in the amount of liquid employed, crystallizes when it cools. The process is based on one published by Wm. Hodgson, jun. in the *Am. Journ. of Pharm.* for July, 1856 (p. 305). The salt consists of one eq. of each of the two salts composing it, with probably 24 eqs. of water of crystallization ($F_2O_3,3SO_3+NH_4O,SO_3+24HO$).

Ammonio-ferric alum is in octohedral crystals, of a pale violet colour, and sour astringent taste, slowly efflorescent on exposure, and soluble in 1·5 parts of water at 60°, and in less than their weight of boiling water. The sulphuric acid is recognised by giving a precipitate with chloride of barium insoluble in nitric acid; the sesquioxide of iron by being thrown down of a reddish-brown colour, by potassa; and the ammonia, by the emission, when the moistened salt is rubbed with the same alkali, of its peculiar odour. According to H. Rose, the pure salt is white, and gives a coloured solution with water, in consequence of the formation of a basic ferruginous salt. This decomposition is prevented by dissolving it in dilute sulphuric acid, when the solution is colourless.

Instead of sulphate of ammonia, sulphate of potassa may be employed along with the tersulphate of iron, in which case a potassa iron-alum is produced, called *potassio-ferric alum*, which has all the properties, physical and remedial, of the ammonio-ferric salt; and the two appear to have been indiscriminately used. The formula of this salt would be $Fe_2O_3,3SO_3+KO,SO_3+24HO$.

The iron alums were brought to the notice of the Pharmaceutical Society of London, in Dec. 1853, by Mr. Lindsley Blyth, as a new remedy, prescribed in St. Mary's Hospital. Dr. Tyler Smith found them to be more astringent than common alum, and devoid of the stimulating effects of the other salts of iron. They have been used internally in leucorrhœa, with great asserted benefit, in diarrhœa and chronic dysentery, and in other affections requiring combined tonic and astringent treatment. (*Pharm. Journ.*, Jan. 1854, p. 306.) The dose is from three to twelve or fifteen grains, to be repeated twice or three times a day. B.

FERRI ET AMMONIÆ TARTRAS. *U. S.* *Tartrate of Iron and Ammonia.*

"Take of Tartaric Acid *twelve troyounces;* Solution of Tersulphate of Iron *two pints and a half;* Carbonate of Ammonia, Distilled Water, each, *a sufficient quantity.* Dissolve six troyounces of the Tartaric Acid in two pints of Distilled Water, and saturate it carefully by means of Carbonate of Ammonia; then add the remainder of the Acid, dissolved in half a pint of Distilled Water, and mix the solutions. With the Solution of Tersulphate of Iron, prepare the Hydrated Oxide of Iron according to the formula for that substance, and add it gradually to the solution of bitartrate of ammonia, kept at the temperature of 150°, until it is no longer dissolved. Then filter the solution, and evaporate to the consistence of syrup. Lastly, spread it on plates of glass, so that, on drying, the salt may be obtained in scales." *U. S.*

This is a new officinal of the U. S. Pharmacopœia, adopted from Prof. Procter, whose process was published in the *American Journal of Pharmacy*, so long since as in 1841 (xii. 276.) Tartrate of ammonia is first prepared, which is converted into bitartrate by the addition of tartaric acid; and the excess of acid is then combined with hydrated sesquioxide of iron freshly prepared from the officinal solution of the tersulphate. A double salt of tartrate of ammonia and tartrate of iron is thus made in solution, which is obtained by filtering and concentrating the solution. The bibasic view of tartaric acid requires a different explanation. According to this, the salt must be considered as consisting of one eq. of tartaric acid, with a doubled equivalent number, and two eqs. of base, one consisting of ammonia and the other of sesquioxide of iron. In the first view, it would be represented by the formula $F_2O_3,C_4H_2O_5 + NH_4O,C_4H_2O_5$; in the second, by $F_2O_3,NH_4O + C_8H_4O_{10}$, independently of the water, which has been estimated between four and five equivalents.

This salt is in transparent garnet-red scales, which when powdered assume a rust-brown colour. It has a sweetish not disagreeable taste, and is very soluble in water though slowly, being taken up by somewhat more than its own weight. It is insoluble in alcohol and ether. Test paper is not affected by it. The fixed alkalies do not precipitate it from its solution, nor is it rendered blue by ferrocyanide of potassium, showing that it contains no protoxide of iron. Incinerated in the air, it leaves 29 per cent. of sesquioxide of iron. It is a mild chalybeate, and may be given in a dose of from ten to thirty grains. W.

FERRI ET POTASSÆ TARTRAS. *U. S.* FERRUM TARTARATUM. *Br.* *Tartrate of Iron and Potassa. Tartarated Iron.*

"Take of Solution of Tersulphate of Iron *a pint;* Bitartrate of Potassa *seven troyounces;* Distilled Water *four pints.* With the Solution of Tersulphate of Iron, prepare the Hydrated Oxide of Iron according to the formula for that substance. Mix the Bitartrate of Potassa with the Distilled Water, heat the mixture to 140°, and, keeping it at that temperature, gradually add the Hydrated Oxide, frequently stirring, until it ceases to be dissolved. Then filter the solution, evaporate it by means of a water-bath to the consistence of syrup, and spread it upon plates of glass or porcelain, so that, on drying, the salt may be obtained in scales." *U. S.*

"Take of Solution of Persulphate of Iron *four fluidounces;* Solution of Soda *two pints* [Imperial measure] or *a sufficiency;* Acid Tartrate of Potash, in powder, *two ounces* [avoirdupois]; Distilled Water *a sufficiency.* Add the Persulphate of Iron to a pint [Imp. meas.] of Distilled Water, and gradually pour the dilute solution into the Solution of Soda, stirring well for a few minutes; then collect the precipitate on a calico filter, and wash it with Distilled Water until the filtrate ceases to become turbid on the addition of chloride of barium. To the Acid Tartrate of Potash and thirty ounces of Distilled Water placed in a

capsule add the precipitate, and digest the mixture with repeated stirring for six hours, at a heat which must be carefully prevented from rising above 140°. After the solution has cooled down to the temperature of the atmosphere, decant it off any undissolved precipitate, and, having poured it in a thin layer on flat porcelain or glass plates, evaporate it to dryness at a temperature not exceeding 140°. Lastly, remove the dried salt in flakes, and preserve it in stoppered bottles." *Br.*

The object of these processes is to combine the excess of acid in the bitartrate of potassa with sesquioxide of iron. In both, the plan of Soubeiran is adopted; namely, that of dissolving the moist hydrated sesquioxide to saturation in a mixture of the bitartrate and water, aided by a moderate heat. The sesquioxide is now obtained from the tersulphate of sesquioxide of iron, which is precipitated either by ammonia (*U. S.*), or by solution of soda (*Br.*). Potassa is not a good precipitant; because the alkali adheres obstinately to the precipitated sesquioxide, and cannot be completely separated even by repeated washings. The sesquioxide should be gradually added to the bitartrate and water, heated to 140°, as recommended by Soubeiran, at which temperature the oxide dissolves more readily and in larger quantity than when a higher temperature is employed. Besides, in the latter case, a portion of the sesquioxide is converted into protoxide. (*Gmelin's Handbook*, x. 315.) In both formulas, the liquid is poured out on a plane surface, so as to dry in scales. When duly carried into effect, they yield a product at all times identical, and having all the required qualities of the salt.*

The late Dr. Ure proposed the *tartrate of protoxide of iron* for medical use. He made it by acting on clean iron filings, or bits of iron wire, with a solution of tartaric acid. It is a pulverulent salt, insoluble in water, and possessing a mild chalybeate taste.

Properties. Tartrate of iron and potassa, as obtained by the above formulas, is in transparent scales of a ruby-red colour, and wholly soluble in about four parts of water. It has a sweetish slightly chalybeate taste. Its solution does not

* *A new method of preparing this salt.* M. Roger, having found the tartrate of iron and potassa, as existing in the shops of Paris, a very variable salt, seldom presenting perfect identity of composition in any two specimens, and ascribing this result to the imperfection of the prevalent mode of preparing it, which requires a large amount of water, and consequently a prolonged evaporation, resulting in the reduction of the sesquioxide, and the production of a yellowish insoluble ferrous salt, and is attended besides with various other inconveniences, proposes the following method, which he conceives to be free from these objections, and to present in all instances an identical product. The newly proposed method consists in causing, as a first step, strongly hydrated sesquioxide of iron to be dissolved in tartaric acid to complete saturation, for which purpose the water of hydration of the sesquioxide is sufficient at a temperature of 100° to 120° F. The solution takes place completely and quickly; and the point of saturation is known when the liquid, at first clear, becomes turbid, thickens, and at last concretes in the form of a jelly. No more of the sesquioxide, which is in slight excess, is now to be added. Upon this jelly is to be poured, little by little, a very concentrated solution of *pure* carbonate of potassa, of which the quantity to be used should be the equivalent of that of the tartaric acid employed. But this precision as to the quantity of the carbonate is not absolutely necessary; as the cessation of effervescence is a sufficient criterion of saturation. Should, however, the solution, upon testing it, be found slightly acid, the solution of carbonate of potassa should be cautiously added till the reaction becomes slightly alkaline. The vessel is then to be removed from the water-bath, and the liquid allowed to cool. Twelve hours afterwards, the liquid is decanted, filtered, and evaporated by means of a water-bath, with constant agitation, to a syrupy consistence. It is then to be spread by means of a brush, in thin layers, on plates of glass, which are to be placed in the drying room. The salt is thus obtained in beautiful spangles, of a deep garnet red. Or it may be dried in moulds of tinned iron with a large surface; but in this case, instead of scales, it forms little black masses not unlike jet. Thus prepared, it always presents the same composition, dissolves in water without residue, and, besides, is little disposed to deliquescence, so that it may be readily employed in pills. The solution, however, is slow in forming, as the salt at first agglomerates at the bottom of the vessel; but in half an hour it is complete, and may be kept long unchanged. (*Journ. de Pharm.*, Juin, 1861, p. 401.)—*Note to the twelfth edition.*

change the colour of litmus, and at common temperatures is not precipitated by potassa, soda, or ammonia. Ferrocyanide of potassium does not render it blue, unless an acid be added. The non-action of this test shows that the iron is in a peculiar state of combination. Acidulated with muriatic acid, the solution gives a copious blue precipitate with the ferrocyanide of potassium, but none with the ferridcyanide, showing the absence of protoxide of iron. In boiling solution, soda precipitates sesquioxide of iron, without evolution of ammonia; and the filtered solution, acidulated with muriatic acid, deposits a crystalline substance when it cools; the latter test showing the presence of tartrate of potassa, the former that of the sesquioxide of iron, and both together the character of the salt. According to the view of its nature taken in the U. S. Pharmacopœia, it is a double salt, consisting of one eq. of tartrate of sesquioxide of iron and one of tartrate of potassa ($Fe_2O_3,C_4H_2O_5 + KO,C_4H_2O_5 + HO$); according to the bibasic view of tartaric acid, recognised in the Br. Pharmacopœia, it is a tartrate with a double base ($Fe_2O_3,KO,C_8H_4O_{10} + HO$), the eq. of tartaric acid being doubled. By incinerating 50 grains at a red heat, and treating the residue with muriatic acid, a solution is obtained, which, digested with a little nitric acid, then diluted with four fluidounces of water, and supersaturated with ammonia, yields a precipitate of sesquioxide of iron weighing 14·92 grains. (*Br.*) The salt is incompatible with astringent vegetable infusions, which give rise to a dark-coloured precipitate.

Medical Properties. Tartrate of iron and potassa is an agreeable chalybeate, and may be depended upon for activity and uniformity of composition. It has a somewhat laxative effect, which makes it suitable to the treatment of certain cases. It is the chalybeate preferred by M. Mialhe, who conceives that it is more readily absorbed than any other ferruginous preparation. It is also well borne by the stomach, whether taken fasting, or with the food. From its slight taste and ready solubility, it is one of the best ferruginous preparations for children. The dose for an adult is from ten grains to half a drachm, given preferably in solution.

Off. Prep. Vinum Ferri, *Br.* B.

FERRI ET QUINIÆ CITRAS. *U. S.*, *Br.* *Citrate of Iron and Quinia.*

"Take of Solution of Citrate of Iron *ten fluidounces;* Sulphate of Quinia *a troyounce;* Diluted Sulphuric Acid, Water of Ammonia, Distilled Water, each, *a sufficient quantity.* Triturate the Sulphate of Quinia with six fluidounces of Distilled Water, and, having added sufficient Diluted Sulphuric Acid to dissolve it, cautiously pour into the solution Water of Ammonia, with constant stirring, until in slight excess. Wash the precipitated Quinia on a filter, and, having added it to the Solution of Citrate of Iron, maintained at the temperature of 120° by means of a water-bath, stir constantly until it is dissolved. Lastly, evaporate the solution to the consistence of syrup, and spread it on plates of glass, so that, on drying, the salt may be obtained in scales." *U. S.*

"Take of Solution of Persulphate of Iron *three fluidounces;* Sulphate of Iron *one ounce* [avoirdupois]; Distilled Water *a sufficiency;* Solution of Soda *thirty-six fluidounces;* Citric Acid, in crystals, *two ounces and a quarter* [avoird.]; Sulphate of Quinia, *three hundred and eighty grains;* Dilute Hydrochloric Acid, Solution of Chloride of Barium, Solution of Ammonia, each, *a sufficiency.* Add the Solution of Persulphate of Iron to the Sulphate of Iron dissolved in ten fluidounces of the Water; mix well, and pour the mixture into the Solution of Soda with constant stirring. Collect the precipitate on a calico filter, and wash with Distilled Water, until the liquid which passes through ceases to give a precipitate with chloride of barium. Dissolve the Citric Acid in twenty fluidounces of the Distilled Water, and, having then added the washed precipitate, digest the mixture on a water-bath, with repeated stirring, until a solution is obtained. In eight fluidounces of the Water acidulated with a little of the Dilute Hydrochloric Acid dissolve the Sulphate of Quinia, add sufficient of the

Solution of Chloride of Barium to precipitate the sulphuric acid, and filter, and having treated the solution with a slight excess of Ammonia, collect the precipitate on a paper filter, and wash it with Distilled Water, until nitrate of silver dropped into the filtrate gives but a very slight precipitate. Transfer the washed quinia to the capsule containing the citrate of iron, and digest on a water-bath until the alkaloid is dissolved. Lastly, let this solution be evaporated in thin layers, on flat porcelain or glass plates, at a temperature below 212°, and let the residue be removed in flakes, and preserved in stoppered bottles." *Br.*

The U. S. process is based on a published formula of Prof. Procter, described in the eleventh edition of this Dispensatory (*page* 1393). It consists simply in dissolving, at a temperature of 120°, in a definite measure of solution of citrate of iron (U. S.), the quinia obtained by precipitating a given weight of sulphate of quinia by water of ammonia. The Br. process is more complicated. First, a mixture of sesquioxide and protoxide of iron is obtained by precipitating a mixture of the sesquisulphate and sulphate in solution by means of soda. Secondly, the mixed oxides thus obtained are digested with a solution of citric acid, so as to produce in solution a citrate of the two oxides. Thirdly, sulphate of quinia, dissolved by means of dilute muriatic acid, is precipitated by chloride of barium so as to separate the sulphuric acid, and from the solution of the muriate of quinia remaining, the quinia is thrown down by ammonia. Lastly, the quinia thus procured is digested with the solution of citrate of iron, and the resulting citrate of iron and quinia is obtained by evaporation. The direction to use nitrate of silver as a test of sufficient washing is to indicate that the muriate of ammonia has been washed away. In both processes the salt is dried on glass or porcelain so as to be obtained in thin scales.

The U. S. and Br. preparations are somewhat different; the former consisting of citric acid, sesquioxide of iron, and quinia; the latter, of citric acid, mixed sesquioxide and protoxide of iron, and quinia. No such analysis of either salt has been made as to determine precisely its equivalent composition; but the U. S. salt is probably a mixture of the proper citrate of iron and quinia with citrate of the sesquioxide.

The characters of the U. S. salt, as given in the Pharmacopœia, are the following. "In thin transparent scales, varying in colour from reddish-brown to yellowish-brown with a tint of green, according to the thickness of the scales. Its taste is ferruginous and moderately bitter. It is slowly soluble in cold water, more readily so in hot water, but insoluble in ether and officinal alcohol. Ammonia, added to the aqueous solution, deepens its colour to reddish-brown, and causes a whitish curdy precipitate of quinia; but no sesquioxide of iron is thrown down."

The British citrate is described as in scales of a greenish golden-yellow colour, of a bitter and chalybeate taste, somewhat deliquescent, which does not seem to be the case with the former salt, and entirely soluble in cold water. Mr. Squire, however, states that, if prepared according to the formula, the scales have a garnet colour (*Compan. to Br. Pharm.*, p. 96); and Mr. Fleurot, after trying the process, has come to the conclusion that it is fallacious (*Pharm. Journ.*, July, 1864, p. 21). The solution is very slightly acid, and is precipitated reddish-brown by soda, white by ammonia, blue by the ferrocyanide and ferridcyanide of potassium, showing the presence of both oxides of iron, and grayish-black by tannic acid. The following tests are given in the Br. Pharmacopœia. "Fifty grains, dissolved in a fluidounce of water, and treated with a slight excess of ammonia, give a white precipitate [quinia] which, when dried, weighs 8 grains. The precipitate is entirely soluble in pure ether, leaves no residue when burned, and, when dissolved by the aid of an acid, forms a solution which, decolorized by a little purified animal charcoal, turns the plane of polarization strongly to the left [all characters of quinia]."

The salt is said to be sometimes adulterated by cinchonia, which would be at once detected by the test of solubility in ether and the effect on polarized light, above given. As it occurs in the British market, it is of exceedingly variable composition, containing according to Mr. J. C. Braithwaite, who examined 15 different specimens, a proportion of quinia varying from 1·5 to 15·84 per cent.; scarcely any two specimens being exactly alike.

Citrate of iron and quinia combines the virtues of its two bases, and may be given in all cases in which iron and quinia are jointly indicated. It is, therefore, admirably adapted to the cases of anæmia, with enlarged spleen, which are so apt to accompany and follow our autumnal fevers. It may be given in pill or solution, in the dose, as a tonic, of five or six grains, containing about a grain of quinia, three or four times a day. This dose may be greatly increased, if deemed advisable. W.

FERRI FERROCYANIDUM. *U. S.* FERRI FERROCYANURETUM. *U. S.* 1850. *Ferrocyanide of Iron. Ferrocyanuret of Iron. Pure Prussian Blue.*

"Take of Ferrocyanide of Potassium *nine troyounces;* Solution of Tersulphate of Iron *a pint;* Water *three pints.* Dissolve the Ferrocyanide of Potassium in two pints of the Water, and add the solution gradually to the Solution of Tersulphate of Iron, previously diluted with the remainder of the Water, stirring the mixture during the addition. Then filter the liquid, and wash the precipitate on the filter with boiling water until the washings pass nearly tasteless. Lastly, dry it, and rub it into powder." *U. S.*

In the U. S. Pharmacopœia of 1850, tersulphate of sesquioxide of iron was prepared as the first step of the process; in the present formula, it is taken already prepared, in the form of the officinal solution. This salt is decomposed by the gradual addition of the solution of ferrocyanide of potassium. Three eqs. of ferrocyanide and two of tersulphate of sesquioxide of iron are mutually decomposed, with the result of forming one eq. of Prussian blue, or the 3–4 ferrocyanide of iron, which precipitates, and six eqs. of sulphate of potassa, which remain in solution. Ferrocyanogen is a tercyanide of iron ($FeCy_3$); and, representing it by its symbol Cfy, we may compactly express the above reaction by the following equation: $3K_2Cfy$ and $2(Fe_2O_3,3SO_3) = Fe_4Cfy_3$ and $6(KO,SO_3)$. Prussian blue contains the elements of six eqs. of water, which cannot be separated without the destruction of the compound. Adding these elements, we may suppose it to become a hydroferrocyanate of the sesquioxide of iron, represented by the formula $2Fe_2O_3,3H_2Cfy$. From the formula given for the anhydrous compound (Fe_4Cfy_3), it is evident that it contains seven eqs. of iron and nine of cyanogen.

Preparation for Use in the Arts. Prussian blue is manufactured on the large scale as follows. A mixture made of equal parts of carbonate of potassa (pearlash of commerce) and of animal matter, such as dried blood, hair, the shavings of horn, &c., is calcined at a red heat, in an iron vessel, until it becomes pasty. The mass, when cold, is thrown, by portions at a time, into twelve or fifteen times its weight of water, with which it is stirred for half an hour. The whole is then put upon a linen filter; and the clear solution obtained is precipitated by a mixed solution of two parts of alum and one of sulphate of protoxide of iron. An effervescence occurs, due principally to carbonic acid; and a very abundant precipitate is thrown down of a blackish-brown colour. This precipitate is washed, by decantation, by means of a large quantity of water, which is removed every twelve hours. By these washings, which last from twenty to twenty-five days, the precipitate becomes successively greenish-brown, bluish, and finally deep-blue. When of the latter colour, it is collected and allowed to drain upon a cloth, after which it is divided into cubical masses and dried. In relation to the manufacture of Prussian blue, see the *Pharmaceutical Journal* (March, 1856, p. 423, and May, 1856, p. 511).

Properties. Pure Prussian blue is a tasteless powder, insoluble in water and alcohol, and having a rich deep-blue colour. It is insoluble in dilute acids, decomposed by fuming nitric acid, and dissolved without decomposition by strong sulphuric acid, forming a white mass of the consistence of paste, from which the Prussian blue may be precipitated unchanged by water. Concentrated muriatic acid decomposes it, dissolving sesquioxide of iron, and liberating hydroferrocyanic acid (H_2Cfy). Boiled with red oxide of mercury, it generates bicyanide of mercury. (See *Hydrargyri Cyanidum.*) By the contact of a red-hot body, it takes fire and burns slowly, leaving a residue of sesquioxide of iron. When it is heated in close vessels, water, hydrocyanic acid, and carbonate of ammonia are evolved, and carburet of iron is left. Its composition has been given above. The Prussian blue of commerce was discovered by accident, in 1710, by Diesbach, a preparer of colours at Berlin. It has the same general properties as the pure substance. It occurs in small rectangular masses, which are heavier than water, and have a fracture presenting a bronzed appearance. Besides the constituents of pure Prussian blue, it always contains uncombined sesquioxide of iron, and a portion of alumina, derived from the alum employed in its manufacture, which serves to give it body as a pigment. These substances may be detected by boiling the pigment with dilute muriatic acid, and precipitating the filtered solution with ammonia. Pure Prussian blue, treated in this manner, yields no precipitate.

Medical Properties, &c. Prussian blue is deemed a tonic, febrifuge, and alterative. Dr. Zollickoffer, of Maryland, recommended it in intermittent and remittent fevers, and deemed it to be particularly adapted to the cases of children, on account of the smallness of the dose and its want of taste. He considers it more certain, prompt, and efficacious than the bark; while it has the advantage of being admissible in the state of pyrexia, and of not disagreeing with the most irritable stomach. It has also been used by Dr. Kirchoff, of Ghent, in epilepsy with advantage. Dr. Bridges, of this city, exhibited it in a case of severe and protracted facial neuralgia, with considerable relief, after the usual remedies for this complaint had been tried with little or no benefit. It is sometimes employed as an application to ill-conditioned ulcers, mixed with simple ointment in the proportion of a drachm to the ounce. The dose of pure Prussian blue is from three to five grains, repeated several times a day, and gradually increased until some obvious effect is produced. B.

FERRI IODIDUM. *Br. Iodide of Iron.*

"Take of Fine Iron Wire *one ounce and a half* [avoirdupois]; Iodine *three ounces* [avoird.]; Distilled Water *fifteen fluidounces.* Introduce the Iodine, Iron, and twelve [fluid]ounces of the Water into a flask, and having heated the mixture gently for about ten minutes, raise the heat and boil until the solution loses its red colour. Pass the solution through a small paper filter into a dish of polished iron, washing the filter with the remainder of the Water, and boil down until a drop of the solution taken out on the end of an iron wire solidifies on cooling The liquid should now be poured out on a porcelain dish, and, as soon as it has solidified, should be broken into fragments, and enclosed in a stoppered bottle." *Br.*

The solid iodide of iron is omitted in the present edition of the U. S. Pharmacopœia, which directs it in the form of pills and syrup prepared immediately from the materials; the iodide itself being so liable to spontaneous change, as to render its preservation for any length of time unaltered almost impossible.

In the Br. process, which is a modification of that of the late Dublin Pharmacopœia, iron is made to unite with iodine by the intervention of water, and the combination takes place readily and quickly. The liquid at first is red or orange-coloured, from the circumstance that all the iodine has not united with the iron; but, after the application of heat, it becomes fully saturated and limpid, and as-

sumes a greenish colour. It is now a solution of iodide of iron, and yields the solid salt by evaporation. The proportion of the iron taken is half the weight of the iodine. Fine iron wire, recently cleaned, is directed on account of its purity; but iron filings dissolve more readily, and, if carefully selected, will be sufficiently pure. It is exceedingly difficult to obtain this salt in the solid state perfectly pure, so great is the proneness of its solution to absorb oxygen, whereby the iodide becomes, in part, converted into sesquioxide. This change is prevented to a certain extent by evaporating to dryness in an *iron* vessel.

The Messrs. T. & H. Smith, of Edinburgh, recommend the following improved process, which more effectually excludes atmospheric air. Boil, in a Florence flask, six drachms of pure iron filings with two ounces and a quarter of iodine, in four and a half ounces of distilled water, until the liquid loses its dark colour. Then filter the liquid rapidly into another flask, and evaporate it, at a boiling heat, until its green shade passes into black. After this period, the heat is kept up as long as the evaporation of moisture continues, which may be ascertained by its condensation on a cold piece of glass, placed, from time to time, over the mouth of the flask. When this ceases, the flask contains pure, anhydrous, spongy iodide of iron, which, when cold, is to be removed by breaking the flask, bruised coarsely in a warm dry mortar, and enclosed immediately in small well-corked bottles. If it is wished to obtain the iodide as a crystallized hydrate, the heat is to be withdrawn as soon as the liquid is sufficiently concentrated to congeal, in a dry and hard crust, on the end of an iron wire dipped into it. A modification of this process by Dr. Squibb will be found in the *American Journal of Pharmacy* for Jan. 1859 (p. 52).

Properties. Iodide of iron is a crystalline substance, exceedingly deliquescent, of a greenish-black colour, and styptic, chalybeate taste. Its solution, by evaporation with as little contact of air as possible, affords transparent, green, tabular crystals. When heated moderately it fuses, and, on cooling, becomes an opaque crystalline mass, having an iron-gray colour and metallic lustre. At a higher temperature it emits violet-coloured vapours, and the iron is left in the state of sesquioxide. It is very soluble both in water and alcohol. When recently prepared it is wholly soluble in water, forming a pale-green solution; but, if made for some time, it almost unavoidably contains some sesquioxide of iron, from a partial decomposition, and will not entirely dissolve. M. Lecoq, of Saint-Quentin, has proposed to preserve it in a wide-mouthed, ground-stoppered bottle, covered with a layer of reduced iron, which cannot decompose it, and protects it from the action of the air. When the iodide is wanted, the iron is removed with a bone spatula, or a little brush. The aqueous solution is very liable to spontaneous decomposition, becoming at last orange-red from the generation of free iodine, and depositing sesquioxide of iron. According to Mr. Richard Phillips, jun., the first step in this change is the formation of protoxide of iron and hydriodic acid, from the decomposition of water. As the protoxide immediately begins to be converted into sesquioxide by absorbing oxygen from the air, and in this state is precipitated, the hydriodic acid is set free; and hence is explained the acidity of the solution from the first moment the sesquioxide is deposited. Afterwards, the hydriodic acid is decomposed by the air, and iodine liberated. When the solution is prevented from generating free iodine, by placing in it a coil of iron wire, according to the plan of Mr. Squire, the iron acts by combining with the iodine of nascent hydriodic acid, and not with nascent iodine. (*Pharm. Journ.*, iv. 19.) The plan of Mr. Squire does not prevent the deposition of sesquioxide, and has, therefore, been superseded by the use of saccharine matter, which affords a better protection to the solution. (See *Syrupus Ferri Iodidi.*) Iodide of iron is incompatible with alkalies and their carbonates, with lime-water, and with all other substances by which sulphate of iron is decomposed. When crystallized it consists of one eq. of iodine 126·3, one of iron 28, and five of water 45 = 199·3.

Medical Properties and Uses. Iodide of iron was first employed in medicine by Dr. Pierquin in 1824. It was first used in the United States in 1832 by Professor Samuel Jackson, of this city, at whose request it was prepared in solution by Mr. E. Durand. Its powers are those of a tonic, alterative, diuretic, and emmenagogue. It acts more like the preparations of iron than like those of iodine It sometimes sharpens the appetite and promotes digestion, and occasionally proves laxative. When it does not operate on the bowels, it generally augments the urine. Its use blackens the stools and lessens their fetor. It is chiefly employed in scrofulous complaints, swellings of the cervical glands, visceral obstructions attended with deficient action, chlorosis, atonic amenorrhœa, and leucorrhœa. In the two diseases last mentioned, Dr. Pierquin employed it with success. Dr. Burguet, of Bordeaux, cured a case of diabetes, of long standing, by the use of the remedy for several months. In obstinate syphilitic ulcers, M. Baumes, of Lyons, used it with satisfactory results. He gave it in the form of pill, conjoined with extract of opium, and sometimes increased the dose to 20 grains in the course of twenty-four hours. In secondary syphilis, occurring in debilitated and scrofulous subjects, Ricord has found it a valuable remedy. The dose is a grain, gradually increased to eight grains or more.

This salt, on account of its deliquescent property, and proneness to decomposition, should not be given in pill, unless protected from change by saccharine matter, or other means. (See *Pilulæ Ferri Iodidi.*) The most convenient form of exhibition is that of syrup.*

For forming enemata, injections for the vagina, and lotions for ulcers, one or two drachms of the iodide may be dissolved in a pint of water. B.

FERRI LACTAS. *U. S. Lactate of Iron.*

"Take of Lactic Acid *a fluidounce;* Iron, in the form of filings, *half a troyounce;* Distilled Water *a sufficient quantity.* Mix the Acid with a pint of Distilled Water in an iron vessel, add the Iron, and digest the mixture on a water-bath, supplying Distilled Water, from time to time, to preserve the measure. When the action has ceased, filter the solution, while hot, into a porcelain capsule, and set it aside to crystallize. At the end of forty-eight hours, decant the liquid, wash the crystals with a little alcohol, and dry them on bibulous paper. By evaporating the mother-water in an iron vessel to one-half, filtering while hot, and setting the liquid aside, more crystals may be obtained." *U. S.*

In this process the iron is protoxidized by the water, and the lactic acid unites with the protoxide, forming lactate of iron, a part of which crystallizes when the solution cools, and the remainder is obtained by evaporation and crystallization. It may be more cheaply prepared, on the large scale, by digesting the impure acid first obtained in M. Louradour's process (see *page* 39), with iron filings, or by reaction between sulphate of iron and the lactate of lime or lactate of zinc prepared as a step in obtaining lactic acid. (*Ibid.*) The following is M. Gobley's process for making lactate of lime, preparatory to its conversion into lactate of iron. Add to 2 pints of skim-milk, diluted with twice its bulk of water, and contained in an earthen pan, 64 drachms of powdered lactin, and 51 drachms of powdered chalk. Allow the whole to ferment for eleven or twelve days, at a temperature of from 80° to 90°, supplying water as it evaporates. Transfer the liquor to a capsule, heat it gradually to boiling, and stir it constantly. Boil for a quarter of an hour to coagulate casein, allow the insoluble matters to subside,

* *Glycerate of Iodide of Iron.* Glycerin has the property at once of dissolving and preserving iodide of iron, and therefore makes an excellent excipient. M. Veza proposes the following formula. "Take of Iodine 35 parts, Iron, in powder, 70 parts, and Glycerin 400 parts. Mix them." The colour of the solution is an emerald green; its taste is bitter and astringent; and tests do not detect in it the presence of free iodine. It may be used for preparing the syrup or pills. Five grains of it contain one of the iodide of iron. (*Journ. de Pharm.*, Octob. 1862, p. 338.)—*Note to the twelfth edition.*

and strain the liquid through flannel. The clear liquid is a solution of lactate of lime. In this process the casein of the milk, acting as a ferment, converts not only the lactin of the milk, but the lactin added, into lactic acid; a result which would not take place were it not for the presence of the chalk, which saturates the lactic acid as it is formed, and prevents it from uniting with the casein, whereby the power of the latter as a ferment would be destroyed. (*Journ. de Pharm.*, 3*e sér.*, vi. 54.) Lactate of lime may be expeditiously converted into lactate of iron by the following process of M. Lepage. Dissolve 100 parts of lactate of lime, obtained by M. Gobley's process, in 500 parts of boiling water; and 68 parts of pure crystallized sulphate of protoxide of iron in 500 parts of cold distilled water. Mix the filtered solutions in a matrass, acidulate slightly with lactic acid, and heat in a water-bath, stirring frequently until the double decomposition is completed. Then filter to separate the sulphate of lime, and evaporate rapidly to one-half, either in an iron vessel, or in a porcelain capsule containing a few turnings of iron. Filter again, and set aside to crystallize; and, having washed the crystals in a funnel with a little alcohol, dry them on bibulous paper. (*Journ. de Pharm.*, 3*e sér.*, ix. 272.) In relation to the precautions to be observed in preparing this lactate, so as to prevent the partial sesquioxidation of the iron, see the paper of M. C. J. Thirault in the *Journal de Pharmacie*, copied into the *Am. Journ. of Pharm.* for Nov., 1853 (p. 556).

Lactate of iron is in greenish-white crystalline crusts or grains, undergoing little change in the air. When in the form of a yellowish or greenish-white powder it is impure. It is but sparingly soluble in water, requiring 48 parts of cold and 12 of boiling water to dissolve it, and is insoluble in alcohol. It has an acid reaction, and possesses a mild, sweetish, ferruginous taste. The aqueous solution quickly becomes yellow, in consequence of the iron passing to a higher state of oxidation. M. Louradour has seen several samples of this lactate, variously adulterated; as with effloresced sulphate of iron, starch, and lactin; the sophistication being concealed by the sale of the salt in powder. These impurities may be detected by appropriate reagents; but M. Louradour recommends, as a simpler way of avoiding them, the rejection of the salt when not in crystalline crusts. "Exposed to heat it froths up, gives out thick, white, acid fumes, and becomes black; sesquioxide of iron being left. If it be boiled for fifteen minutes with nitric acid of the sp. gr. 1·20, a white granular deposit of mucic acid will occur on the cooling of the liquid." (*U. S.*) These tests indicate that it is a lactate of iron.

Medical Properties. Lactate of iron has the general medical properties of the ferruginous preparations. It has a marked effect in increasing the appetite. The disease in which it was principally tried in Paris was chlorosis, with or without amenorrhœa; and in this disease, Andral, Fouquier, Bouillaud, and others obtained very favourable results. The dose is one or two grains, repeated at intervals and gradually increased. As much as 12 or even 20 grains may be given in the course of a day. It may be administered in lozenge, pill, or syrup. The *lozenge* may be made of one grain of the lactate to twelve of sugar; and the *pill*, of one grain of the salt, with an equal weight of some inert powder free from astringent matter, and sufficient honey. The following is the formula for a *syrup* proposed by M. Cap, expressed in the nearest weights and measures used in this country. Take of lactate of iron *a drachm;* white sugar *twelve ounces and a half;* boiling distilled water *six fluidounces and a half.* Rub the salt to powder with half an ounce of the sugar; and dissolve the mixture quickly in the boiling water. Pour the solution into a matrass placed on a sand-bath, and add to it the rest of the sugar in small pieces. When the sugar is dissolved, filter the syrup, and, as soon as it is cold, transfer it to bottles which must be well stopped. This syrup has a very light amber colour, and contains about four grains of the salt to the fluidounce. The dose is from two to four fluidrachms. Bread, called *chalybeate bread*, containing lactate of iron in the proportion of

about a grain to the ounce, has been used with advantage by chlorotic patients in one of the hospitals of Paris. The bread is not injured in taste or quality. Prof. Brainard, of Chicago, has treated, with success, a large erectile tumour of the orbit, by infiltrating it by injection with a fluidrachm of a solution of lactate of iron, containing eight grains of the salt. (*Ranking's Abstract*, xviii. 253.) B.

FERRI OXIDUM HYDRATUM. *U. S.* Ferri Peroxidum Hydratum. *Br. Hydrated Oxide of Iron. Hydrated Peroxide of Iron. Hydrated Sesquioxide of Iron.*

"Take of Solution of Tersulphate of Iron *a pint;* Water of Ammonia, Water, each, *a sufficient quantity.* To the Solution of Tersulphate of Iron, previously mixed with three pints of Water, add Water of Ammonia, with constant stirring, until in slight excess. Then pour the whole on a wet muslin strainer, and wash the precipitate with water until the washings pass nearly tasteless. Lastly, mix the precipitate with sufficient Water to make the mixture measure a pint and a half, and transfer it to a wide-mouthed bottle, which must be well stopped.

"When Hydrated Oxide of Iron is to be made in haste for use as an antidote, the washing may be performed more quickly, though less perfectly, by pressing the strainer forcibly with the hands until no more liquid passes, and then mixing the precipitate with sufficient Water to bring the mixture to the measure of a pint and a half." *U. S.*

"Take of Solution of Persulphate of Iron *four fluidounces;* Solution of Soda *thirty-three fluidounces*, or *a sufficiency;* Distilled Water *one pint* [Imperial measure]. Add the Persulphate of Iron to the Distilled Water, and gradually pour the dilute solution into the Solution of Soda, stirring well for a few minutes; collect the precipitate on a calico filter, and wash it with distilled water, until the filtrate ceases to give a precipitate with chloride of barium. Lastly, enclose the precipitate, without drying it, in a porcelain pot whose lid is made tight by a luting of lard. This preparation should be recently made." *Br.*

This preparation was introduced into the officinal catalogues on account of its importance as an antidote to arsenious acid. In the former processes the first step was to convert the sulphate of protoxide of iron into the tersulphate of sesquioxide; but in the present the officinal solution of tersulphate of iron (persulphate, *Br.*) is taken already containing the iron in the proper state of oxidation. This is simply treated with water of ammonia (*U. S.*), or diluted solution of soda (*Br.*), which throws down the sesquioxide combined with water, constituting the hydrated sesquioxide required. After due washing, it is mixed with water in order to maintain its pulpy state, and then carefully enclosed in bottles, which should be wide-mouthed, in order to permit its ready extraction.

Besides having this antidote ready formed in the pulpy state, it is the duty of the apothecary to be always prepared to make it, by keeping the necessary solutions for its precipitation; namely, the solution of tersulphate of sesquioxide of iron and solution of ammonia. In relation to this subject the reader is referred to a paper by Prof. Procter, in the *American Journal of Pharmacy* for March, 1853 (p. 104).

Properties. Hydrated oxide of iron, as directed to be kept by the U. S. formula, is a soft, moist, reddish-brown magma. If dried at a heat not exceeding 180°, and afterwards pulverized, it forms a reddish-brown powder, not attracted by the magnet, being the sesquioxide in the state of hydrate, containing about 18 per cent. of water. In this state it is wholly and readily soluble in muriatic acid without effervescence. If exposed to a red heat it loses the combined water, and becomes the anhydrous sesquioxide, less easily soluble in acids, improper for medicinal use, and altogether without effect as an antidote. Hydrated oxide of iron consists of one eq. of sesquioxide 80, and two of water $18 = 98$, and is represented by the formula $Fe_2O_3 + 2HO$. Kept for some time in the pulpy state,

it loses half its combined water, and becomes less soluble in acids, and less efficient as an antidote.

Medical Properties and Uses. The hydrated oxide of iron is not an eligible ferruginous preparation for medical use. Its antidotal powers in poisoning by arsenic, the manner in which it acts, the circumstances which impair its efficiency, and the mode of using it are fully explained under arsenious acid (*page* 28). Its power of rendering arsenious acid insoluble is readily shown by agitating a solution of the acid with a considerable excess of the moist oxide, filtering, and then testing the filtered solution for the acid; not a trace of the metal can be detected, even by sulphuretted hydrogen. The hydrated oxide, as obtained by the U. S. formula, contains a little ammonia, which is thought by some to assist its antidotal powers. At least it has been ascertained that the sesquioxide, when precipitated by potassa as formerly directed by the Dublin College, is less efficient than when precipitated by ammonia, and must be employed in quantities three or four times as large to produce the same effect. The dry hydrate, rubbed up with water, is in the same proportion weaker than the pulpy hydrate. It has already been mentioned, under arsenious acid, that the officinal subcarbonate of iron (formerly called precipitated carbonate) possesses antidotal powers to arsenic, though in an inferior degree; but this statement will not apply to it, after it has been exposed to a red heat, to which it is improperly subjected by some manufacturing chemists. By ignition it becomes anhydrous, and altogether inefficient as an antidote.

Off. Prep. Ferri Peroxidum, *Br.* B.

FERRI OXIDUM MAGNETICUM. *Br. Magnetic Oxide of Iron. Martial Ethiops.*

"Take of Sulphate of Iron *six ounces* [avoirdupois]; Sulphuric Acid *three fluidrachms;* Nitric Acid *two fluidrachms;* Solution of Soda *fifty-eight fluidounces,* or *a sufficiency;* Distilled Water *a sufficiency.* Add the Sulphuric Acid to five fluidounces of the Water, and with the aid of heat dissolve in the mixture four ounces [avoird.] of the Sulphate of Iron. Mix the Nitric Acid with two fluidounces of the Water, and, having added the dilute acid to the solution of sulphate of iron, concentrate by boiling until, on the sudden disengagement of ruddy vapours, the liquid passes from a dark to a red colour. To the solution thus obtained add the two remaining ounces of Sulphate of Iron, first dissolved in half a pint [Imperial measure] of Distilled Water. Mix well, add to the liquid the Solution of Soda, and, having boiled for five minutes in an iron vessel, collect the precipitate on a calico filter, and wash it with boiling Distilled Water, until the liquid which passes through ceases to give a precipitate when allowed to drop into a solution of chloride of barium. Lastly, dry the precipitate without heat in a confined portion of air over a capsule containing sulphuric acid, and enclose it in a stoppered bottle." *Br.*

In this formula, two-thirds of the sulphate of protoxide of iron taken are converted into tersulphate of sesquioxide. The remaining third of the sulphate is then dissolved in water, and mixed with the solution of the tersulphate. A compound solution is thus obtained, containing two-thirds of the iron in the state of sesquioxide, and one-third in that of protoxide. When this solution is treated with soda, a mixed precipitate of one eq. of protoxide and one of sesquioxide is thrown down (FeO,Fe_2O_3). Now such a compound oxide corresponds in composition with the native magnetic black oxide. The precipitate is washed to remove sulphate of soda, and the washings are known to be completed when the chloride of barium ceases to give a precipitate with them.

Properties, &c. The artificial magnetic oxide of iron is a brownish-black powder, without taste, and strongly magnetic. According to the Br. Pharmacopœia, it consists of peroxide (sesquioxide) of iron (Fe_2O_3) with about 9 per cent. of protoxide (FeO), and 22 per cent. of water. It dissolves without effer-

vescence in muriatic acid diluted with half its bulk of water; and the solution gives a blue precipitate both with the ferrocyanide and ferridcyanide of potassium, showing the presence both of the protoxide and sesquioxide of iron.

The Br. Pharmacopœia gives the following tests. "Twenty grains moistened with nitric acid, and calcined at a low red heat, leave 15·8 grains of peroxide [sesquioxide] of iron. Twenty grains dissolved in hydrochloric acid continue to give a blue precipitate with ferridcyanide of potassium until 8·3 measures of the *volumetric solution of bichromate of potash* have been added." The former test measures the whole ferruginous strength of the preparation, the protoxide being sesquioxidized by the nitric acid and heat; the second the quantity of protoxide present, which must be such as to require the indicated quantity of the bichromate for its sesquioxidation. The dose is from five to twenty grains, given several times a day.

Scales of iron (*ferri squamæ*) were formerly officinal with the Dublin College under the name of black oxide. They were prepared from the scales, found at the blacksmith's anvil, by washing them with water, separating them from impurities by means of a magnet, and reducing them to a fine powder. They are of variable composition; being mixtures of the two oxides of iron with metallic iron. In view of their want of uniformity in composition, they were abandoned by the College for the magnetic oxide. B.

FERRI PEROXIDUM. *Br. Peroxide of Iron. Sesquioxide of Iron.*

"Take of Hydrated Peroxide of Iron *four ounces.* Place the Peroxide of Iron in a stove or oven until it becomes dry to the touch, and then expose it to a heat of 212° until it ceases to lose weight. Lastly, reduce it to a fine powder, and preserve it in a bottle." *Br.*

This is the late Dublin process slightly modified. The hydrated oxide (Fe_2O_3. 2HO) loses, by the process, one-half of its combined water, and is converted into the monohydrated sesquioxide (Fe_2O_3,HO), which is the present officinal preparation. As prepared by the Dublin process, in which it was heated to redness, it lost the second eq. of water, and became the anhydrous sesquioxide (Fe_2O_3), identical with the *colcothar* of commerce.

Properties, &c. This oxide is a reddish-brown, tasteless, insoluble powder, differing from colcothar in containing an eq. of water. It should not be deliquescent, and should dissolve entirely in muriatic acid without effervescence. Its solution in diluted muriatic acid yields a copious blue precipitate with the ferrocyanide of potassium, but none with the ferridcyanide; showing that it contains sesquioxide of iron but no protoxide. If it contain copper, its muriatic solution will deposit this metal on a bright piece of iron. This oxide is not used as a medicine. It is employed in making iron plaster and reduced iron, for which purposes other forms of oxidized iron would answer as well. The former Dublin *rubigo ferri* or *rust of iron*, formed by exposing moistened iron wire to the air till converted into rust, is essentially the sesquioxide, containing a little carbonate of the protoxide.

Off. Prep. Emplastrum Ferri, *Br.;* Ferrum Redactum, *Br.* B.

FERRI PHOSPHAS. *U.S., Br. Phosphate of Iron.*

"Take of Sulphate of iron *five troyounces;* Phosphate of Soda *six troyounces;* Water *eight pints.* Dissolve the Salts separately, each in four pints of the Water; then mix the solutions, and set the mixture by that the precipitate may subside. Lastly, having poured off the supernatant liquid, wash the precipitate with hot water, and dry it with a gentle heat." *U. S.*

"Take of Sulphate of Iron *three ounces* [avoirdupois]; Phosphate of Soda *two ounces and a half* [avoird.]; Acetate of Soda *one ounce* [avoird.]; Boiling Distilled Water *four pints* [Imperial measure]. Dissolve the Sulphate of Iron in one-half of the Water, and the Phosphate and Acetate of Soda in the

remaining half. Mix the two solutions, and, after careful stirring, transfer the precipitate to a calico filter, and wash it with hot distilled water, till the filtrate ceases to give a precipitate with chloride of barium. Finally dry on porous bricks in a stove whose temperature does not exceed 100°. Preserve the dried salt in a stoppered bottle." *Br.*

The U. S. preparation is the result of a double decomposition between the saline materials employed. As the medicinal phosphate of soda is the middle tribasic phosphate, having the composition $2NaO,HO,PO_5$, it follows that it requires two eqs. of sulphate of protoxide of iron for its decomposition, as shown by the following equation: $2(FeO,SO_3)$ and $2NaO,HO,PO_5 = 2FeO,HO,PO_5$ and $2(NaO,SO_3)$. The resulting salts, therefore, are one eq. of the middle tribasic phosphate of iron, the salt under notice, and two eqs. of sulphate of soda, which are washed away. If the ferruginous sulphate be a perfect sulphate of the protoxide, the precipitate as first thrown down will be white; but it quickly absorbs oxygen and becomes bluish-white. When perfect it consists of two eqs. of protoxide of iron, one of basic water, and one of phosphoric acid; but generally it contains some phosphate of the sesquioxide without basic water (Fe_2O_3,PO_5).

The British phosphate of iron is a different salt; for, while the former has two eqs. of oxide of iron, this has three eqs. to one of the acid; the third eq. being supplied by the acetate of soda used in the process. Supposing the double decomposition to have occurred, as in the U. S. process, between two eqs. of the sulphate of iron and one of the double-based phosphate of soda, producing two eqs. of sulphate of soda and one of the double-based phosphate of iron; the reaction next takes place between the generated eq. of phosphate of iron, one eq. of sulphate of iron, and one of acetate of soda, resulting in the production of an additional eq. of sulphate of soda, an eq. of free acetic acid, and the addition of a third eq. of oxide of iron to the phosphate, which, being insoluble, is precipitated. This latter result arises from the strong disposition of the tribasic phosphoric acid to combine with three bases, which could only be satisfied by the liberation of an eq. of the acetic acid of the acetate. This salt, when first formed, is represented by the formula $3FeO,PO_5$; but the strong affinity of its protoxide for oxygen causes the gradual production of sesquioxide, which, therefore, to a certain extent always exists in the preparation.

Phosphate of iron, by whichever process procured, is in the form of a powder of a bright slate colour, insoluble in water, but soluble in acids. The solution in dilute muriatic acid gives a blue precipitate with both ferridcyanide and ferrocyanide of potassium, but much the more copiously with the former, proving the presence both of protoxide and sesquioxide of iron, but a great preponderance of the protoxide. With ammonia the same solution yields a precipitate insoluble in an excess of the alkali. This is a test of the U. S. Pharmacopœia, probably intended to show that the salt, while containing a portion of phosphate of sesquioxide of iron, has been quite freed by washing from phosphate of soda; for, though a precipitate is produced by ammonia with the phosphate of the protoxide, it is redissolved by an excess of the precipitant, whereas, with the sesquioxide salt, the precipitate is not redissolved by such excess, unless by the aid of phosphate of soda or other salt of similar powers. If the preparation contain arsenic, it will be detected by producing a dark precipitate on the surface of a slip of pure copper introduced into the solution.

Phosphate of iron, dissolved to saturation in a boiling solution of metaphosphoric acid (HO,PO_5), under the name of *superphosphate of iron*, was proposed as a new remedy, in Jan. 1851, by Dr. Routh, of London. Mr. Thomas Greenish, of the same city, states that the solution of the salt, on cooling, hardens into a mass of a pilular consistence, soluble in water in all proportions, and free from any disagreeable or inky taste. He has prepared from it a syrup, containing five grains of the salt to the fluidrachm.

Medical Properties. Phosphate of iron possesses the general properties of the ferruginous preparations, and has been given with advantage in amenorrhœa and some forms of dyspepsia. It was introduced into the U. S. Pharmacopœia at the suggestion of the late Dr. Hewson, of this city, who found it, after an extensive experience, to be a valuable chalybeate. The dose is from five to ten grains.* B.

FERRI PYROPHOSPHAS. *U. S. Pyrophosphate of Iron.*

"Take of Phosphate of Soda *seven troyounces and a half;* Solution of Tersulphate of Iron *seven fluidounces,* or *a sufficient quantity;* Citric Acid *two troyounces;* Water of Ammonia *five fluidounces and a half,* or *a sufficient quantity;* Water *a sufficient quantity.* Heat the Phosphate of Soda, in a porcelain capsule, until it undergoes the watery fusion, and continue the heat until it becomes dry. Transfer the dry salt to a shallow iron capsule, and heat it to incipient redness, without fusion. Then dissolve it in three pints of Water, with the aid of heat, and, having filtered the solution and cooled it to the temperature of 50°, add Solution of Tersulphate of Iron until this ceases to produce a precipitate. Stir the mixture thoroughly, and pour it upon a muslin strainer, and, when the precipitate has drained, wash it with water until the washings pass nearly tasteless, and transfer it to a weighed porcelain capsule.

"To the Citric Acid, contained in a suitable vessel, add Water of Ammonia until the Acid is saturated and dissolved. Then add the solution to the precipitate in the weighed capsule, stir them together, and evaporate until the liquid is reduced to sixteen troyounces. Spread this on plates of glass or porcelain, so

* *Compound Syrup of Phosphate of Iron. Chemical Food.* For a formula for a compound syrup of phosphate of iron by Mr. Wiegand, made by introducing into it the phosphates of lime, potassa, and soda, and for remarks on the pharmacy of the phosphates by Prof. Procter, see the *Am. Journ. of Pharm.* for March, 1854 (pp. 111 and 112). A formula similar to Mr. Wiegand's, communicated by Mr. Edward Parrish, as probably representing the process for a secret preparation considerably used in this city, may be found in the *Am. Journ. of Pharm.* for Nov. 1857 (p. 573). These formulas are too complicated to have any therapeutic value. Nevertheless, as the preparations have had much vogue, under the name of *chemical food*, we give the formula of Mr. Parrish from the journal referred to. "Take of Protosulphate of Iron ℥x; Phosphate of Soda ℥xii; Phosphate of Lime ℥xii; Glacial Phosphoric Acid ℥xx; Carbonate of Soda ℈ij; Carbonate of Potassa ℥i; Muriatic Acid, Water of Ammonia, each, q. s.; Powdered Cochineal ℥ij; Water q. s. to make f℥xx; Sugar ℔ij (troy); Oil of Orange ♏x. Dissolve the Sulphate of Iron in f℥ij, and the Phosphate of Soda in f℥iv of boiling Water. Mix the solutions, and wash the precipitated phosphate of iron till the washings are tasteless. Dissolve the Phosphate of Lime in f℥iv of boiling Water with sufficient Muriatic Acid to make a clear solution, precipitate it with Water of Ammonia, and wash the precipitate. To the freshly precipitated phosphates add the Phosphoric Acid previously dissolved in Water. When clear add the Carbonates of Soda and Potassa, and afterwards sufficient Muriatic Acid to dissolve the precipitate. Now add the Cochineal mixed with the Sugar, apply heat, and when the syrup is formed, strain and flavour it. Each teaspoonful contains about one grain of phosphate of iron and two and a half grains of phosphate of lime, with smaller quantities of the alkaline phosphates, all in perfect solution." The objection to such preparations as this is not that each of the ingredients may not be useful; but that they are so numerous that a morbid state of system must be extremely rare in which they can all be indicated, and every medicine is more or less noxious if given when it is not needed. The probability is that the therapeutic value of the preparation depends mainly on its ferruginous ingredient, and that, as a general rule, its therapeutic effects may be equally as well, if not better obtained, from a simple syrup of phosphate of iron.

Simple Syrup of Phosphate of Iron. Subsequently, Mr. Wiegand gave a formula for a simple syrup of phosphate of iron, made by dissolving the recently precipitated salt in muriatic acid, and adding the requisite quantity of sugar. By a misprint the phosphate of soda taken is double what it should be. The same writer has proposed to make a syrup of the phosphates of iron and lime, by dissolving in the above a definite quantity of recently precipitated phosphate of lime, made by double decomposition between solutions of chloride of calcium and phosphate of soda. See his formulas in the *Am. Journ. of Pharm.* for March, 1855 (p. 104). —*Notes to the tenth, eleventh and twelfth editions.*

that, on drying, the salt may be obtained in scales. Lastly, preserve it in a well-stopped bottle, protected from the light." *U. S.*

This formula appears to be based upon a method, proposed by M. E. Robiquet to the Academy of Medicine at Paris, in Feb. 1857, of preparing pyrophosphate of iron for use, by dissolving a gelatinous precipitate of the salt in a solution of citrate of ammonia, and forming a syrup with the solution. Prof. Procter devised a formula upon this plan, published in the *Am. Journ. of Pharm.* (Nov. 1857, p. 573), the result of which also was a syrup. The officinal formula, which provides for the preparation of the salt in the solid form, capable of being readily made into a syrup if desired, is that of Dr. Squibb published in the same journal (Jan. 1860, p. 37).

The first step in the officinal process is to convert the common tribasic phosphate of soda ($2NaO,HO,PO_5 + 24HO$), by moderately igniting it, into the pyrophosphate or bibasic phosphate of soda ($2NaO,PO_5$), which may be obtained crystallized by dissolving it in boiling water and evaporating, in which state it is represented by the formula $2NaO,PO_5 + 10HO$. The uncrystallized pyrophosphate is dissolved and mixed with solution of tersulphate of iron, when the pyrophosphate of sesquioxide of iron is deposited. This, while in a pulpy state, is added to a solution of citrate of ammonia formed by a direct union of its constituents, by which it is dissolved. The process is completed by evaporating the solution sufficiently, and then spreading it out to dry on glass or porcelain so that the salt may be obtained in scales. The reactions which result in the formation of the ferruginous salt, contained in this compound, probably take place between three eqs. of the bibasic phosphate of soda $3(2NaO,PO_5)$ and two eqs. of the tersulphate of iron $2(Fe_2O_3,3SO_3)$, forming six eqs. of sulphate of soda, and one eq. of sesquiphosphate of sesquioxide of iron, having (according to Gmelin) the equivalent composition represented by the formula $2Fe_2O_3,3PO_5 + 9HO$.

The preparation is probably an intimate mixture of the ferruginous and ammoniacal salts in the solid form; at least such must be the view of the revisers of the Pharmacopœia, who name it pyrophosphate of iron. It is in scales of an apple-green colour, and an acidulous somewhat saline taste. It is wholly and freely dissolved by water. Ferrocyanide of potassium occasions no precipitate with its solution, though it causes a pale-blue colour, showing that the iron is in the state of sesquioxide, and that there is a substance present (citrate of ammonia) capable of holding ferrocyanide of iron in solution. The salt contains 48 per cent. of anhydrous pyrophosphate of iron. (*U. S.*) It is a very good chalybeate, mild yet efficient in its action on the system, without disagreeable taste, and, from its solubility, readily administered in any form that may be desirable, whether that of pill, simple solution in water, or syrup. The dose is from two to five grains. A syrup may be readily prepared by dissolving it in water, and mixing the solution with simple syrup.* W.

* This ferruginous pyrophosphate is soluble in pyrophosphate of soda; and hence, if an excess of pyrophosphate of soda is used in the double decomposition, the ferruginous pyrophosphate, first thrown down, is redissolved. This solution was proposed as a medicine by M. Persoz in 1848, and by M. Leras in 1849. M. Leras conceives that pyrophosphate of iron, rendered soluble by pyrophosphate of soda, is the only ferruginous preparation which is not precipitated in the stomach by the agency of the food or gastric juice. Mr. Alex. Ure, of London, tried this solution, calling it *soda-pyrophosphate of iron*, in scrofula, and found it a mild and efficient chalybeate. The same solution, as prepared by M. Leras, has been employed with marked success in anemic diseases, by MM. Follet and Baume, who found it easily administered and rapidly absorbed. In the preparation used by him, the sulphate of soda, resulting from the double decomposition, was allowed to remain. The same solution, including the sulphate of soda, has been prepared as a syrup by M. Soubeiran.

Syrup of Pyrophosphate of Iron. M. Soubeiran's formula is as follows. Add 55 *grains* of tersulphate of sesquioxide of iron, dissolved by a gentle heat in 2 *fluidounces* of water, to

FERRI SUBCARBONAS. *U. S. Subcarbonate of Iron. Sesquioxide of Iron. Red Oxide of Iron. Precipitated Carbonate of Iron. Aperitive Saffron of Mars.*

"Take of Sulphate of Iron *eight troyounces;* Carbonate of Soda *nine troyounces:* Water *eight pints.* Dissolve the salts separately, each in four pints of the Water; then mix the solutions, and, having stirred the mixture, set it by that the precipitate may subside. Having poured off the supernatant liquid, wash the precipitate with water until the washings pass nearly tasteless, and dry it on bibulous paper without heat." *U. S.*

When the solutions of carbonate of soda and sulphate of iron are mixed together, a hydrated carbonate of protoxide of iron, of a pale-blue colour,* is thrown down, and sulphate of soda remains in solution. The equivalent quantities of the *crystallized salts* for mutual decomposition are 139 of the sulphate and 143·3 of the carbonate. Taking the quantity of sulphate of iron at 8 parts, the U. S. Pharmacopœia orders 9 parts of the carbonate of soda, which gives a slight excess of the latter. The precipitate, during the washing and drying, absorbs oxygen, and loses nearly all its carbonic acid, whereby it is converted almost entirely into sesquioxide of iron. Hence, the London College gave it the name of *Ferri Sesquioxidum;* but, as this is applicable to the red oxide, obtained by calcining the sulphate, or igniting the hydrated sesquioxide, the U. S. name of *Ferri Subcarbonas*, adopted in allusion to the small quantity of carbonic acid present in it, is more distinctive. Carbonate of soda is preferred to carbonate of potassa for decomposing the ferruginous sulphate; because it produces in the double decomposition sulphate of soda, which, from its greater solubility, is more readily washed away than sulphate of potassa. The direction to dry the precipitate without heat is important; as even a moderate elevation of temperature has been shown, by the experiments of Mr. J. A. Rex, to modify the resulting product unfavourably, diminishing its solubility in muriatic acid in proportion to the heat employed. (*Am. Journ. of Pharm.*, May, 1862, p. 193.)

Properties. Subcarbonate of iron is a reddish-brown powder, of a disagreeable, slightly styptic taste; insoluble in water, and not readily dissolved by any acid except the muriatic, with which it effervesces slightly. When of a bright-red colour it should be rejected, as this colour shows that it has been injured by exposure to heat. After precipitation from its muriatic solution by ammonia or potassa, either of which throws down the sesquioxide of iron, the supernatant liquor should give no indications of containing any metal in solution by the test of sulphuretted hydrogen or ferrocyanide of potassium. It is incompatible with acids and acidulous salts. In composition it is a hydrated sesquioxide of iron, containing a little carbonate of the protoxide. By exposure to a red

462 grains of crystallized pyrophosphate of soda, dissolved in 7½ *fluidounces* of water and 8½ *fluidounces* of mint water, and mix. So soon as the precipitate formed redissolves, filter the solution, and add to the filtrate 19 *troyounces* of white sugar, which must be allowed to dissolve without heat. The dose of this syrup, which is easy to take, is a tablespoonful, containing about a third of a grain of iron.

An equivalent preparation may be made from the U. S. pyrophosphate of iron by dissolving 2·6 grains in a fluidounce of syrup; but this would be a feeble preparation; and, besides, the quantity of sugar might be embarrassing to the stomach. A better plan would probably be to dissolve 20 grains in a fluidounce of syrup, giving 2·5 grains of the salt to each fluidrachm, and making the dose from one to two teaspoonfuls. The salt may be dissolved in a little water before being incorporated with the syrup, care being taken that the resulting liquid should contain 20 grains to the fluidounce.

Dr. Squibb prepares a syrup of the pyrophosphate by adding to 24 parts of the solution of the formula, after filtration, 248 parts of Syrup, and thus obtains a preparation containing about two grains of the officinal salt, or one grain of the anhydrous pyrophosphate, in a fluidrachm.—*Notes to the eleventh and twelfth editions.*

* The carbonate of the protoxide of iron is white if perfectly pure; but as the sulphate of iron used is not absolutely pure, containing almost always a little sesquioxide, this is thrown down with the carbonate, giving it a bluish tinge.

heat, it absorbs oxygen, and loses water and carbonic acid, being converted into the *astringent saffron of Mars* of the French Codex. After ignition it is no longer a subcarbonate, but is converted into the pure sesquioxide, which is less soluble in acids, and less efficient as a medicine than the preparation in its original state. Hence it is wrong to expose the subcarbonate to a red heat, as some manufacturing chemists are in the habit of doing, in order to give it a bright-red colour.

Medical Properties and Uses. Subcarbonate of iron is tonic, alterative, and emmenagogue, and is employed for all the purposes to which the preparations of iron are generally applicable. It was recommended by Mr. Carmichael in cancer, and is said sometimes to prove useful. Mr. Hutchinson brought it into notice as a remedy for neuralgia; and an extensive experience with it in that disease has established its value. It is also useful in chorea, chlorosis, and, generally, in those diseases in which the blood is deficient in red corpuscles. It has been used by Dr. Woollam, Dr. Shearman, Dr. Elliotson, and others in traumatic tetanus, with success in twelve cases, and failure in three. In the second stage of hooping-cough, Dr. Steymann represents it to be a prompt and efficacious remedy. When prescribed as a tonic, the usual dose is from five to thirty grains three times a day, given in pill or powder, and frequently combined with aromatics and vegetable tonics. In neuralgia, chorea, and tetanus, it is administered in doses of from one to two teaspoonfuls. No nicety need be observed in the dose; as its only obvious effect in very large doses is a slight nausea, and a sense of weight at the stomach. It blackens the stools.

The subcarbonate of iron acts as an antidote to the poison of arsenious acid, provided it has not been exposed to a red heat; and, though not so powerful as the hydrated oxide in the form of magma, should always be used until the latter can be procured. (See *page* 30.)

FERRI SULPHAS. *U. S.*, *Br.* *Sulphate of Iron. Green Vitriol.*

"Take of Iron, in the form of wire, and cut in pieces, *twelve troyounces;* Sulphuric acid *eighteen troyounces;* Water *eight pints.* Mix the Sulphuric Acid and Water, and add the Iron; then heat the mixture until effervescence ceases. Pour off the Solution, and, having added thirty grains of Sulphuric Acid, filter through paper, allowing the lower end of the funnel to touch the bottom of the receiving vessel. Evaporate the filtered liquor in a matrass until sufficiently concentrated; then set it aside in a covered vessel to crystallize. Drain the crystals in a funnel, dry them on bibulous paper, and keep them in a well-stopped bottle." *U. S.*

"Take of Iron Wire *four ounces* [avoirdupois]; Sulphuric Acid *four fluidounces* [Imperial measure]; Distilled Water *one pint and a half* [Imp. meas.]. Pour the Water on the Iron placed in a porcelain capsule, add the Sulphuric Acid, and, when the disengagement of gas has nearly ceased, boil for ten minutes. Filter now through paper, and, after the lapse of twenty-four hours, separate the crystals which have been deposited from the solution. Let these be dried on filtering paper placed on porous bricks, and preserved in a stoppered bottle." *Br.*

The object of these processes is to make a pure sulphate of protoxide of iron by direct combination. Sulphuric acid, in a concentrated state, acts but imperfectly on iron; but when diluted, a vigorous action takes place, the oxygen of the water converts the metal into protoxide, with which the sulphuric acid unites, and hydrogen is evolved. The equivalent quantities for mutual reaction are 28 of iron to 49 of acid. This proportion is one part of iron to one and three-quarters of acid. The *U. S.* proportion is one part of iron to one and a half of acid, and gives a quantity of iron one-sixth more than the acid can dissolve. The

British Council uses an excess of acid, the weight of acid taken being 7·38 avoirdupois ounces, instead of 7. An excess of iron, however, is desirable; as it tends to secure the production of a perfect sulphate of the protoxide. The remaining steps of the U. S. process are peculiar, and are intended to secure the formation of a salt, entirely free from sesquioxide, by the method of Bonsdorff. This chemist found that, when a perfect sulphate of protoxide of iron was formed in solution by heating dilute sulphuric acid with an excess of iron, it might be crystallized free from sesquioxide, provided a little excess of sulphuric acid were added to the liquid before filtration, in order to hold in solution any sesquioxide that may have been formed; at the same time avoiding, as much as possible, the contact of the air. Hence the directions in the U. S. formula to acidulate with sulphuric acid, to cause the funnel to touch the bottom of the receiving vessel, which avoids the dropping of the liquid through the air, and to cover the vessel containing the concentrated liquid, when it is set aside to crystallize. The *London* and *Edinburgh Colleges* prepared this officinal by purifying the impure commercial sulphate; but their plan was superseded by that of the *Dublin College* in the recent consolidation of the several pharmacopœias in the British.

Properties. Sulphate of iron is in the form of transparent crystals, efflorescent in the air, of a pale bluish-green colour, and having the shape of oblique rhombic prisms. It has a styptic taste, and an acid reaction. As prepared by Bonsdorff's method, it is blue verging to green. When it becomes more green than blue, or entirely green, an indication is afforded that it contains some sesquioxide. By exposure to the air the crystals absorb oxygen, and become first green, and ultimately covered with a yellow efflorescence of monosulphate of the sesquioxide, insoluble in water. Sometimes the crystals are quite permanent when made by Bonsdorff's method, owing to the slight excess of acid which they contain. Sulphate of iron is soluble in about twice its weight of cold water, and in three-fourths of its weight of boiling water, but is insoluble in alcohol. The aqueous solution is bluish-green; but by standing it attracts oxygen, and is rendered first green and then reddish, depositing, in the mean time, a portion of sesquisulphate of the sesquioxide, having the composition $2Fe_2O_3,3SO_3 + 8HO$. (Wittstein, *Chemical Gazette*, May 15, 1849, from *Buchner's Reperl.*) When heated moderately, it parts with six-sevenths of its water of crystallization, and becomes grayish-white. (See *Ferri Sulphas Exsiccata.*) At a red heat it loses its acid, and is converted into the anhydrous sesquioxide of iron called *colcothar*. It is incompatible with the alkalies and their carbonates, soaps, lime-water, the chlorides of calcium and barium, the borate and phosphate of soda, nitrate of silver, and the acetate and subacetate of lead. It is decomposed also by astringent vegetable infusions, the tannic and gallic acids of which form, if any sesquioxide be present, a black compound of the nature of ink. The extent to which this change lessens the activity of the salt is not well ascertained. Sulphate of iron, as kept in the shops, is often the impure commercial sulphate, which is not fit for medicinal use.* The perfectly pure salt is precipitated white

* *Commercial Sulphate of Iron.* Ferri Sulphas Venalis. *Lond. Green Vitriol. Copperas.* This was formerly officinal in the London Pharmacopœia, in which it was employed for preparing the pure sulphate. It is manufactured on a large scale for the purposes of the arts, from the native sulphuret of iron, or iron pyrites, by roasting, oxidation by exposure to air and moisture, and lixiviation. The constituents of the mineral become sulphuric acid and protoxide of iron, which, by their union, form the salt. Sulphate iron is also obtained in many chemical processes as a collateral product, as in the manufacture of alum, in the precipitation of copper from solutions of sulphate of copper by scraps of iron, &c.

Commercial sulphate of iron is far from being pure. Besides containing some sesquioxide of iron, it is generally contaminated with metallic and earthy salts; such as those of copper, zinc, alumina, and magnesia. Two principal kinds occur in the market; one in large grass green crystals, the surface of which is studded with ochreous spots; the other, of a bluish-green colour, and ordinarily mixed with the powder of the effloresced salt. The commercial sulphate should never be dispensed by the apothecary, until it has undergone

by ferrocyanide of potassium; but that of ordinary purity gives a greenish precipitate, more or less deep, with this test, owing to the presence of some sesquioxide of iron. Copper may be detected by immersing in the solution a bright piece of iron, on which a cupreous film will be deposited. Both copper and zinc may be discovered by sesquioxidizing the iron by boiling the solution of the salt with nitric acid, and then precipitating the iron by an excess of ammonia. If the filtered solution is blue, copper is present; and if it contain zinc, this will be separated in flakes of white oxide, on expelling the excess of ammonia by ebullition. Sulphate of iron, when crystallized, consists of one eq. of acid 40, one of protoxide 36, and seven of water 63 = 139, and its formula is $FeO,SO_3 + 7HO$.

Medical Properties and Uses. Sulphate of iron is astringent and tonic. In large doses it is apt to produce nausea, vomiting, griping, and purging; and its use, when long continued, injures the stomach. As its effect is chiefly that of an astringent, it cannot be used with advantage to improve the quality of the blood. As an astringent it is given in diseases attended with immoderate discharges; such as passive hemorrhages, colliquative sweats, diabetes, chronic mucous catarrh, leucorrhœa, gleet, &c. As a tonic it is used in dyspepsia, and in the debility following protracted diseases. In amenorrhœa with deficient action it is resorted to with supposed advantage, either alone or conjoined with the fetid and stimulant gums. Externally, the solution is used in chronic ophthalmia, leucorrhœa, and gleet, made of various strengths, from one or two, to eight or ten grains of the salt to the fluidounce of water. M. Velpeau has found it an excellent remedy in erysipelas, applied topically in the form of solution or ointment. In forty cases in which it was tried, it cut short the disease in from 24 to 48 hours. The solution was made of three and a half drachms of the salt to a pint of water, and applied by compresses, kept constantly wet. In a few cases convenience required the application of the ointment, made of eight parts of the salt to thirty of lard. An ointment, made of one or two parts of the sulphate to sixty of lard, was found by M. Devergie to be particularly efficacious in certain skin diseases, especially in the different forms of eczema. In scaly affections it had no effect. The dose is one or two grains, in the form of pill, which should be made from the dried sulphate. (See *Ferri Sulphas Exsiccata.*) When given in solution, the water should be previously boiled to expel the air, which, if allowed to remain, would partially decompose the salt. Taken in an overdose it acts as a poison.

FERRI SULPHAS EXSICCATA. *U. S., Br. Dried Sulphate of Iron.*

"Take of Sulphate of Iron, in coarse powder, *twelve troyounces.* Expose it, in an unglazed earthen vessel, to a moderate heat, with occasional stirring, until it has effloresced; then increase the heat to 300°, and maintain it at about that temperature until the salt ceases to lose weight. Lastly, reduce the residue to fine powder, and keep it in a well-stopped bottle." *U. S.*

"Take of Sulphate of Iron *four ounces.* Expose the Sulphate of Iron in a

a careful purification. The following was the formula of the London College for effecting this object.

"Take of Commercial Sulphate of Iron *four ounces* [*troy*]; Sulphuric Acid *a fluidounce* [Imperial measure]; Iron wire *an ounce* [*troy*]; Distilled Water *four pints* [Imp. meas.]. Mix the Acid with the Water, and add to them the Sulphate and Iron, then apply heat, stirring occasionally, till the Sulphate is dissolved. Filter the solution while hot, and set aside to crystallize. Pour off the liquor, and evaporate it that crystals may again form. Dry all the crystals."—*Note to the twelfth edition.*

porcelain capsule to a moderate heat, which may be finally raised to 400°, until aqueous vapour ceases to be given off. Reduce the residue to a fine powder, and preserve it in a stoppered bottle." *Br.*

In these processes six eqs. out of seven of the water of crystallization of the salt are driven off. The heat should not exceed 400°, otherwise the salt itself would suffer decomposition. Dried sulphate of iron is used for making pills, the crystallized sulphate not being adapted to that purpose. In prescribing the dried sulphate it is necessary to recollect that three grains are equivalent to five of the crystallized salt. B.

FERRI SULPHAS GRANULATA. *Br. Granulated Sulphate of Iron.*

"Take of Iron Wire *four ounces* [avoirdupois]; Sulphuric Acid *four fluidounces* [Imperial measure]; Distilled Water *one pint and a half* [Imp. meas.]; Rectified Spirit *eight fluidounces* [Imp. meas.]. Pour the Water on the Iron placed in a porcelain capsule, add the Sulphuric Acid, and, when the disengagement of gas has nearly ceased, boil for ten minutes, and then filter the solution into a jar containing the spirit, stirring the mixture so that the salt shall separate in minute granular crystals. Let these, deprived by decantation of adhering liquid, be transferred on filtering paper to porous bricks, and dried by exposure to the atmosphere. They should be preserved in a stoppered bottle." *Br.*

The directions given in the first part of this process are precisely the same as those laid down by the British Council for making Sulphate of Iron; but the hot solution of the iron in the sulphuric acid, instead of being allowed to filter into an empty vessel, is made to drop into a portion of rectified spirit, the mixture being stirred while it cools. The acid directed is in excess; and the filtrate is consequently an acid solution of sulphate of protoxide of iron, mixed with spirit. The stirring as the mixture cools finely granulates the salt, which separates perfectly pure; the spirit holding in solution any tersulphate of sesquioxide of iron which may have been formed, and the excess of acid dissolving any free sesquioxide. This process, in its main features, is the same as that of M. Berthemot, given in the eighth edition of this work. It was adopted from the Dublin Pharmacopœia.

Properties, &c. Granulated sulphate of iron is a crystalline, granular, bluish-white powder. When carefully dried it undergoes no change by keeping. It appears to have been introduced into the catalogue of the Dublin Pharmacopœia of 1850, as the best form of the sulphate for conversion into the officinal dried salt; and its peculiar state of aggregation would seem to fit it for that purpose; yet this intention, if it existed, seems to have been overlooked in the revision of the British Pharmacopœia, in which the granulated salt is not directed in the formula for the dried sulphate. The only reason for its retention was probably that it is less liable to oxidation on exposure than the sulphate in its ordinary form.

Off. Prep. Syrupus Ferri Phosphatis, *Br.* B.

FERRUM REDACTUM. *U.S., Br.* Ferri Pulvis *U.S.* 1850. *Reduced Iron. Powder of Iron.*

"Take of Subcarbonate of Iron *thirty troyounces.* Wash the Subcarbonate thoroughly with water until no traces of sulphate of soda are indicated by the appropriate tests, and calcine it in a shallow vessel until free from moisture. Then spread it upon a tray, made by bending an oblong piece of sheet-iron in the form of an incomplete cylinder, and introduce this into a wrought iron reduction-tube, of about four inches in diameter. Place the reduction-tube in a charcoal furnace; and, by means of a self-regulating generator of hydrogen, pass through it a stream of that gas, previously purified by bubbling successively through solution of subacetate of lead, diluted with three times its volume of

water, and through milk of lime, severally contained in four-pint bottles, about one-third filled. Connect with the further extremity of the reduction-tube, a lead tube bent so as to dip into water. Make all the junctions air-tight by appropriate lutes; and, when the hydrogen has passed long enough to fill the whole of the apparatus to the exclusion of atmospheric air, light the fire, and bring that part of the reduction-tube, occupied by the Subcarbonate, to a dull-red heat, which must be kept up so long as the bubbles of hydrogen, breaking from the water covering the orifice of the lead tube, are accompanied by visible aqueous vapour. When the reduction is completed, remove the fire, and allow the whole to cool to the ordinary temperature, keeping up, during the refrigeration, a moderate current of hydrogen through the apparatus. Withdraw the product from the reduction-tube, and, should any portion of it be black instead of iron-gray, separate such portion for use in a subsequent operation. Lastly, having powdered the Reduced Iron, keep it in a well-stopped bottle. When thirty troyounces of Subcarbonate of Iron are operated on, the process occupies from five to eight hours." *U. S.*

"Take of Peroxide of Iron *one ounce* [avoirdupois]; Zinc, granulated, Sulphuric Acid of commerce, Chloride of Calcium, each, *a sufficiency*. Introduce the Peroxide of Iron into a gun-barrel, confining it to the middle part of the tube by plugs of asbestos. Pass the gun barrel through a furnace, and, when it has been raised to a strong red heat, cause it to be traversed by a stream of hydrogen gas, developed by the action on the Zinc of some of the Sulphuric Acid diluted with eight times its volume of water. The gas before entering the gun-barrel must be rendered quite dry by being made to pass first through the remainder of the Sulphuric Acid, and then through a tube eighteen inches long, packed with minute fragments of the Chloride of Calcium. The farther end of the gun-barrel is to be connected by a cork with a bent tube dipping under water; and when the hydrogen is observed to pass through the water at the same rate that it bubbles through the Sulphuric Acid, the furnace is to be allowed to cool down to the temperature of the atmosphere, the current of hydrogen being still continued. The reduced iron is then to be withdrawn, and enclosed in a dry stoppered bottle." *Br.*

This preparation was introduced into the U. S. and Dublin Pharmacopœias of 1850, and is retained in the present edition of our own, and in the British. It consists of metallic iron in fine powder, obtained by reducing the sesquioxide by hydrogen at a dull-red heat. The subcarbonate of the U. S. Pharmacopœia, which is essentially the sesquioxide of iron, is deprived of water by calcination, and then subjected to the reducing influence of a stream of hydrogen, purified from sulphuretted hydrogen and other acid by passing successively through a solution of subacetate of lead and milk of lime. The hydrogen unites with the oxygen of the sesquioxide to form water, and leaves the iron in the metallic state. The subcarbonate should be perfectly free from sulphate of soda, which it is apt to contain when imperfectly washed. If this salt be present it will be reduced by the hydrogen to the state of sulphuret of sodium, which will contaminate and spoil the metallic iron formed, and cause the preparation, when taken, to give rise to unpleasant eructations. The heat should be carefully regulated; for if it fall below dull redness, part of the oxide will escape reduction; and, if it exceed that point considerably, the particles of reduced iron will agglutinate, and the preparation will be heavy and not readily pulverizable. The British process is not so well fitted for practical purposes as that of the U. S. Pharmacopœia. The direction to dry the hydrogen is unnecessary. On the subject of powder of iron, manufacturing chemists will find it useful to consult the paper of MM. Soubeiran and Dublanc, in which full directions are given for purifying the hydrogen, constructing the furnace, regulating the heat, and avoiding explosions. (*Amer. Journ. of Pharm.*, xviii. 303, from the *Journ. de Pharm.*,

viii. 187.) Prof. Procter, of Philadelphia, has made some improvements in the process of Soubeiran and Dublanc, which he has communicated in a paper, embracing many useful details. (*Amer. Journ. of Pharm.*, xix. 11.)

Since the tenth edition of this work was published, several processes have been proposed for obtaining powder of iron. Mr. Arthur Morgan, of Dublin, recommends the use of dried ferrocyanide of potassium, thoroughly mixed with anhydrous red oxide of iron, and calcined with pure carbonate of potassa at a low red heat. The product contains all the iron in a reduced state, mixed with soluble matters, which are carefully washed away. (See *Amer. Journ. of Pharm.*, Sept. 1854, p. 450.) A similar process to the above has been proposed by a German chemist, named Zängerle; the oxalate of protoxide of iron being substituted for the red oxide. (See *Pharm. Journ.*, May, 1857, p. 565.) Prof. Wöhler recommends the use of the same oxalate, not in connection with ferrocyanide of potassium; but as a suitable compound of iron for reduction by hydrogen. Oxalate of protoxide of iron is a salt of a lemon-yellow colour, and may be obtained by precipitating a concentrated solution of sulphate of iron with oxalic acid. Another eligible compound for reduction is the crystalline powder of oxide of iron, prepared by fusing, in a clay crucible, pure dried sulphate of iron with three times its weight of chloride of sodium, and then washing the melted mass when cold, until everything soluble is removed. (*Wöhler.*) The process of M. Eugene Fegueux consists in reducing the oxide of iron by carbonic oxide, formed by passing a stream of carbonic acid over red-hot charcoal in the reduction tube, before it reaches the oxide of iron. The carbonic acid, thus reduced to carbonic oxide, is formed again by the deoxidizing of the ferruginous oxide.

Properties. Powder of iron, called by the French, *fer reduit*, is a light, tasteless powder, soft to the touch, of an iron-gray colour, and without metallic lustre. If black the preparation is to be rejected as not being fully deoxidized. When thrown into a dilute acid, it causes a lively effervescence of hydrogen. A small portion of it, struck on an anvil with a smooth hammer, forms a scale, having a brilliant metallic lustre. On account of its great liability to oxidation, it should be kept in a dry bottle, well stopped. A black powder, having a composition corresponding with that of the magnetic oxide of iron, has been sold in London and Edinburgh under the name of Quevenne's iron. The spurious powder may be known by its having a black instead of an iron-gray colour, and by its effervescing but slightly with acids. In the process for making reduced iron, part of the sesquioxide almost always escapes full deoxidation, and comes out of the tube of a black colour. This part should be rejected, instead of being sold as reduced iron, as appears to have been done by some manufacturing chemists. If the preparation has been very badly made, its solution in dilute sulphuric acid will produce an intensely red colour with sulphocyanide of potassium.

Medical Properties. Powder of iron, reduced from the oxide by hydrogen, was first prepared for medicinal purposes by Quevenne and Miquelard, of Paris. The general therapeutic properties of the preparations of iron, and the mode in which they should be given, have been stated under another head. (See *page* 193.) Of these, the preparation under consideration is among the most important. It is that which introduces the largest proportion of iron into the gastric juice, according to Quevenne, and to M. Costes, of Bordeaux. The chief objection to it is the difficulty of obtaining it well prepared. Much of the powder of iron found in the shops is not to be depended on, in consequence of imperfect reduction. The principal diseases in which it has been employed are anæmia, chlorosis, amenorrhœa, chorea, and enlargement of the spleen following intermittent fever. Its general mode of action is to improve the quality of impoverished blood. Observations to determine its therapeutic value, compared with that of the other ferruginous preparations, were made by M. Costes, for nearly

four years, at the hospital Saint-André, of Bordeaux, and with results highly favourable to it. The dose is from three to six grains several times a day, given in powder or pill. It is sometimes prepared with chocolate in the form of lozenges. B.

HYDRARGYRUM.

Preparations of Mercury.

Of the mercurial preparations formerly officinal, the following have been discarded in the recent editions of the U. S. and British Pharmacopœias; *Pure Mercury*, Dub., *Solution of Bichloride of Mercury*, Lond., *Black Oxide of Mercury*, U. S., *Black Sulphuret of Mercury*, U. S., and *Mercury with Magnesia*, Dub. The *Solution of Nitrate of Mercury* has been transferred to the LIQUORES or *Solutions*.

HYDRARGYRI CHLORIDUM CORROSIVUM. *U. S.* HYDRARGYRUM CORROSIVUM SUBLIMATUM. *Br.* HYDRARGYRI BICHLORIDUM. *Lond.* *Corrosive Chloride of Mercury. Bichloride of Mercury. Corrosive Sublimate.*

"Take of Mercury *twenty-four troyounces;* Sulphuric Acid *thirty-six troyounces;* Chloride of Sodium *eighteen troyounces.* Boil, by means of a sand-bath, the Mercury with the Sulphuric Acid until a dry white mass is left. Rub this, when cold, with the Chloride of Sodium in an earthenware mortar; then sublime with a gradually increasing heat." *U. S.*

"Take of Sulphate of Mercury *twenty ounces* [avoirdupois]; Chloride of Sodium, dried, *ten ounces* [avoird.]; Black Oxide of Manganese, in fine powder, *one ounce* [avoird.]. Reduce the Sulphate of Mercury and the Chloride of Sodium each to fine powder, and, having mixed them and the Oxide of Manganese thoroughly by trituration in a mortar, place the mixture in a tall matrass of green glass, and, by a regulated heat applied through the intervention of sand, let the corrosive sublimate be sublimed. The matrass must now be broken in order to remove the sublimate, which should be kept in jars or bottles impervious to the light." *Br.*

In order to understand the above processes, which are the same in principle, it is necessary to premise that corrosive sublimate is a bichloride of mercury, consisting of two eqs. of chlorine and one of mercury. By boiling sulphuric acid in excess with mercury to dryness, a white salt is formed, which is a bisulphate of the deutoxide of mercury. (See *Hydrargyri Sulphas.*) When this is mixed with chloride of sodium (common salt), and the mixture exposed to a subliming heat, a mutual decomposition takes place. The chlorine of the common salt combines with the mercury, and sublimes as bichloride of mercury; while the sodium, oxygen of the deutoxide of mercury, and sulphuric acid unite to form sulphate of soda, which remains behind. The quantities for mutual decomposition are two eqs. of chloride of sodium, consisting of two eqs. of chlorine and two of sodium; and one eq. of bisulphate of deutoxide of mercury, consisting of one eq. of mercury, two of oxygen, and two of sulphuric acid. The two eqs. of chlorine combine with the one eq. of mercury to form one eq. of corrosive sublimate; and the two eqs., severally, of sodium, oxygen, and sulphuric acid form, by their union, two eqs. of dry sulphate of soda. The British formula differs from ours in ordering the bisulphate of the deutoxide of mercury ready formed, under the name of sulphate of mercury, instead of preparing it as the first step of the process, and in the use of a small proportion of black oxide of manganese, intended to deutoxidize any portion of protoxide of mercury that may be contained in the sulphate, and thereby prevent the formation of protochloride of mercury or calomel. (See *Hydrargyri Sulphas.*)

The names given in the two Pharmacopœias to this important chloride, do

not exactly correspond. It is called the corrosive chloride of mercury in the U. S. Pharmacopœia, and corrosive sublimate, irrespective of chemical nomenclature, in the British. Thus far, no harm can arise from the want of conformity, as neither of these names can be mistaken; but, unfortunately, it has been deemed proper, in the Br. Pharmacopœia, immediately after the officinal title, and in close connection with it, to define the salt as chloride of mercury, in conformity with the new view, adopted in that work, of the equivalent of mercury. Now this view is by no means universally accepted, and, with many, calomel is still the chloride of mercury; so that there is some chance that, should calomel be prescribed by this title, corrosive sublimate may be dispensed for it, with dangerous if not fatal effects to the patient. Indeed, death has, at least in one recorded instance, occurred in consequence of this confusion of nomenclature; and our officinal guides should take especial care to guard against such mistakes, instead of contributing to them.

Preparation on the Large Scale, &c. The first step is to form the bisulphate of the deutoxide of mercury, which is effected by heating the sulphuric acid and metal together in an iron pot, so arranged as to carry off the unwholesome fumes of sulphurous acid, which are copiously generated. The dry salt obtained is then mixed with the common salt, and the mixture sublimed in an iron pot lined with clay, and covered by an inverted earthen pan. The late Dr. A. T. Thomson, of London, took out a patent for forming corrosive sublimate, on the large scale, by the direct combination, by combustion, of gaseous chlorine with heated mercury. The product is stated to be perfectly pure, and to be afforded at a lower price than the sublimate made in the usual way. In order that the combination may take place, the mercury need not be heated to its boiling point, but only to a temperature between 300° and 400°. According to Dr. Maclagan, corrosive sublimate, made by this process, is liable to the objection that a proportion of calomel is always formed, occasionally amounting to 10 per cent.

It may sometimes be useful to know how to make a small quantity of corrosive sublimate on an emergency. This may be done by dissolving deutoxide of mercury (red precipitate) in muriatic acid, evaporating the solution to dryness, dissolving the dry mass in water, and crystallizing. Here a double decomposition takes place, resulting in the formation of water and the bichloride.

Properties. Corrosive chloride of mercury, as obtained by sublimation, is in the form of colourless crystals, or of white, semi-transparent, crystalline masses, of the sp. gr. 5·2, permanent in the air, and of an exceedingly acrid, styptic, metallic, durable taste. It dissolves in 16 parts of cold water, and in 3 of boiling water. A boiling saturated solution, upon cooling, lets it fall in a confused mass of crystals. It is soluble also in 2·3 parts of cold alcohol, in about its own weight of boiling alcohol, and in 3 parts of ether. The latter solvent is capable of removing corrosive sublimate, to a considerable extent, from its aqueous solution, when agitated with it. According to M. Mialhe, ether will not dissolve it when accompanied by a considerable quantity of deutoxide of mercury, and a chloride of an alkalifiable metal. Sulphuric, nitric, and muriatic acids dissolve it without alteration. When heated it melts, and readily sublimes in dense, white, acrid vapours, which condense, on cool surfaces, in white shining needles. Its aqueous solution renders green the syrup of violets, and is precipitated brick-red, becoming yellow, by the fixed alkalies and alkaline earths, and white by ammonia. (See *Hydrargyrum Ammoniatum.*) The former precipitate is the hydrated deutoxide of mercury, which has the property of emitting oxygen, and of being reduced to metallic globules when exposed to heat. This oxide is formed in the process for preparing *aqua phagedænica*, called also *lotio flava* or *yellow wash*, which is obtained by mixing half a drachm of corrosive sublimate with a pint of lime-water. Corrosive sublimate forms with muriate of ammonia and chloride of sodium, compounds which are more soluble than the uncombined mercurial

salt. It is on this account that aqueous solutions of sal ammoniac, or of common salt, dissolve much more corrosive sublimate than simple water. The combination of corrosive sublimate with muriate of ammonia was formerly called *sal alembroth* or *salt of wisdom.* According to F. Hinterberger, corrosive sublimate is capable of combining with quinia and cinchonia. (*Chem. Gaz.*, ix. 211.)

Corrosive sublimate has the property of retarding putrefaction. Animal matters, immersed in its solution, shrink, acquire firmness, assume a white colour, and become imputrescible. On account of this property it is usefully employed for preserving anatomical preparations.

Test of Purity and Incompatibles. Pure corrosive chloride of mercury sublimes, when heated, without residue, and its powder is entirely and readily soluble in ether. Consequently, if a portion of any sample should not wholly dissolve in ether, or if it should not evaporate entirely, the presence of some impurity is proved. If calomel be present, it will not be wholly soluble in water. Corrosive sublimate is incompatible with many of the metals, the alkalies and their carbonates, soap, lime-water, tartar emetic, nitrate of silver, the acetates of lead, the sulphurets of potassium and sodium, and all the hydrosulphates. It is decomposed by many vegetable and some animal substances. According to Dr. A. T. Thomson, it produces precipitates in infusions or decoctions of chamomile, horse-radish, columbo, catechu, cinchona, rhubarb, senna, simaruba, and oak-bark. MM. Mialhe and Lepage have shown that corrosive sublimate is slowly converted into calomel by syrup of sarsaparilla and syrup of honey, but is not changed by contact with pure syrup. B.

Medical Properties and Uses. Corrosive sublimate is a very powerful preparation, operating quickly, and, if not properly regulated, producing violent effects. It is less apt to salivate than most other mercurials. In minute doses, suitably repeated, it may exert its peculiar influence without any obvious alteration of the vital functions, except, perhaps, a slight increase in the frequency of the pulse, and in the secretions from the skin and kidneys. Sometimes, however, it purges; but this effect may be obviated by combining it with a little opium. In larger doses it occasions nausea, vomiting, griping pain in the bowels, diarrhœa, and other symptoms of gastric and intestinal irritation; and in still larger quantities produces all the effects of a violent corrosive poison. It has long been used as a remedy in syphilis, in all stages of which it has been highly recommended. It is said to remove the symptoms more speedily than other mercurials; whilst its action is less unpleasant, as the mouth is less liable to be made sore. For the latter reason it has been much employed by empirics, and is an ingredient in most of those nostrums which have at various periods gained a temporary popularity as anti-venereals. But, while it is extolled by some authors, others, among whom is Mr. Pearson, of London, deny its extraordinary merits, and maintain that, though occasionally useful in arresting the progress of the complaint, particularly in the secondary stage, it does not produce permanent cures, and, in the primary stage, often fails altogether. On the whole it appears to be best adapted to secondary syphilis, in which it occasionally does much good. It is also used advantageously in some chronic cutaneous affections, and in obstinate chronic rheumatism. It is usually associated with alterative or diaphoretic medicines, such as the antimonials, and the compound decoction or syrup of sarsaparilla; and, in order to obviate the irritation it is apt to produce, it may often be advantageously united with opium, or extract of hemlock. There is no doubt that many of the substances, in connection with which it is employed, alter its chemical condition; but it does not follow that, even in its altered state, it may not be very useful as a remedy.

Externally employed, corrosive sublimate is stimulant and escharotic. A solution in water, containing from an eighth to half a grain in the fluidounce, is employed as an injection in gleet, as a gargle in venereal sorethroat, and as a

collyrium in chronic venereal ophthalmia. A stronger solution, containing one or two grains in the fluidounce, is an efficacious wash in lepra, and other scaly eruptions. Dissolved in water, in the proportion of five to ten grains to the fluidounce, it may be used with much benefit in venereal ulcers of the throat, to which it should be applied by means of a camel's hair pencil. With lime-water it forms the *aqua phagedænica* of the older writers, employed as a wash for ill-conditioned ulcers. The powdered chloride has been used as an escharotic; but is, in general, inferior to nitrate of silver or caustic potassa. In *onychia maligna*, however, it is employed with great advantage, mixed with an equal weight of sulphate of zinc, and sprinkled thickly upon the surface of the ulcer, which is then to be covered with a pledget of lint saturated with tincture of myrrh. The whole diseased surface is thus removed, and the ulcer heals. This practice originated, we believe, with the late Dr. Perkins, of Philadelphia, and was highly recommended by Dr. Physick. We have often employed it with complete success. A solution of corrosive sublimate in collodion, in the proportion of four parts of the former to thirty of the latter, has of late been used as a caustic, for the destruction of nævi materni, and for other purposes. It has the advantages that it may be applied to parts of inconvenient access for ordinary caustics, and forms a well defined boundary, without risk of spreading. It is applied by means of a camel's hair pencil.

The dose of corrosive sublimate is from the twelfth to the quarter of a grain, repeated three or four times a day, and given in pill, or dissolved in water or spirit. The pill, which is the preferable form, is usually prepared with crumb of bread; and care should be taken that the medicine be equally diffused through the pilular mass, before it is divided. Mucilaginous drinks are usually given to obviate the irritating effects of the medicine.

Toxicological Properties. Swallowed in poisonous doses, it produces burning heat in the throat, excruciating pain in the stomach and bowels, excessive thirst, anxiety, nausea and frequent retching with vomiting of bloody mucus, diarrhœa and sometimes bloody stools, small and frequent pulse, cold sweats, general debility, difficult respiration, cramps in the extremities, faintings, insensibility, convulsions, and death. The mucous membrane of the stomach exhibits, on dissection, signs of the operation of a violent corrosive poison. These symptoms are sometimes followed or conjoined with others indicating an excessive mercurial action upon the system, such as inflammation of the mouth and salivary glands, profuse salivation, fetid breath, &c. A case is on record of death, in an infant, from the constitutional effects of corrosive sublimate sprinkled upon an excoriated surface; and, in two instances of children, the one seven, and the other nine years old, death, with all the symptoms of internal poisoning, followed the application to the scalp of an ointment, said to consist of one part of the corrosive chloride to four parts of tallow. (*Dub. Quarterly*, Aug. 1854, p. 70.) In the inferior animals, in whatever mode introduced into the system, it is said to occasion irritation of the stomach and rectum, inflammation of the lungs, oppression of the brain, and depression if not inflammation of the heart. (*Christison.*) In the treatment of poisoning by corrosive sublimate, Orfila recommends the free use of the white of eggs beat up with water. The albumen forms an insoluble and comparatively innocent compound with the corrosive sublimate; and the liquid by its bulk dilutes the poison, and distends the stomach so as to produce vomiting. It is, however, asserted by M. Lassaigne that this compound of albumen and corrosive sublimate, when recently precipitated, is soluble in acid and alkaline liquids, and in solutions of the chlorides of potassium sodium, and calcium. (See *Journ. de Pharm.*, xxiii. 510.) It is also soluble in an excess of albumen, whether introduced into the stomach, or previously existing there. It is, therefore, important, at the same time that the antidote is used, to evacuate the stomach before the newly formed compound can be dissolved.

If eggs cannot be procured, wheat flour may be substituted; gluten having, according to M. Taddei, the same effect as albumen. Milk has also been recommended, in consequence of the insoluble compound which casein forms with the poison. Besides the antidotes mentioned, Peruvian bark, meconic acid, protosulphuret of iron, and iron filings have been proposed, all of which have the property of decomposing corrosive sublimate. The protosulphuret of iron was found quite successful by M. Mialhe in experiments upon dogs, if given immediately after the poison was swallowed, but failed when delayed for ten minutes. Dr. T. H. Buckler, of Baltimore, made some experiments on lower animals upon the antidotal properties of a mixture of gold dust and iron filings, which, proving successful, were published in the *Medical and Surgical Journal* in 1843; and a case of poisoning by corrosive sublimate has recently been recorded by Dr. Ch. Johnston, of the same city, in which the antidote was employed with the apparent effect of saving life, after albumen had been used without effect. Dr. Johnston, however, employed the reduced iron of the Pharmacopœia, and gold leaf, arranging them in alternate layers, so as to make boluses of convenient size. (*Am. Journ. of Med. Sci.*, April, 1863, p. 340.) The method of operating of this antidote will be understood, when the action of gold and iron as a test for corrosive sublimate is explained in the succeeding paragraph. It is of the utmost importance that whatever antidote is used should be given without delay, and in this respect the one nearest at hand may be considered the best. Should neither of the substances mentioned be attainable, mucilaginous drinks should be largely administered; and, in any event, the patient should be made to drink copiously, so long as vomiting continues, or till the symptoms are relieved. Should he be unable to vomit, the stomach should be washed out by means of the stomach pump. The consecutive inflammation should be treated with general or local bleeding, fomentations, and cooling mucilaginous drinks; and the attendant nervous symptoms should be alleviated by opiates. W.

Tests for Corrosive Sublimate. On account of the extreme virulence of this chloride as a poison, the reagents by which it may be detected form a subject of study of the utmost importance, as connected with medico-legal investigations. The best tests for determining its mercurial nature, mentioned in the order of their delicacy, are ferrocyanide of potassium, lime-water, carbonate of potassa, iodide of potassium, ammonia, sulphuretted hydrogen, and protochloride of tin. *Ferrocyanide of potassium* gives rise to a white precipitate (ferrocyanide of mercury), becoming slowly yellowish, and at length pale-blue. *Lime-water* throws down a yellow precipitate of hydrated deutoxide. *Carbonate of potassa* causes a brick-red precipitate of carbonate of mercury. *Iodide of potassium* produces a very characteristic pale-scarlet precipitate of biniodide of mercury. This precipitate frequently appears at first yellow, especially if the corrosive sublimate be present in minute proportion. *Ammonia* gives rise to a white, flocculent precipitate, the officinal ammoniated mercury, or white precipitate. *Sulphuretted hydrogen* occasions a black precipitate of bisulphuret of mercury; and the same precipitate is thrown down by hydrosulphuret of ammonia. Finally, *protochloride of tin* causes a grayish-black precipitate (mercury in a finely divided state), and, as a test, is not liable to any fallacy. Taking the results of Devergie, the relative delicacy of these tests may be expressed numerically as follows:—Ferrocyanide of potassium $1\frac{1}{2}$; lime-water 4; carbonate of potassa 7; iodide of potassium 8; ammonia 36; sulphuretted hydrogen or hydrosulphuret of ammonia 60; and protochloride of tin 80. To the above the following tests may be added, easily applied even by one unacquainted with chemistry. *A bright plate of copper*, immersed in a solution containing corrosive sublimate, is instantly tarnished, and, after the lapse of half an hour, becomes covered with a grayish-white powder. *A polished piece of gold*, moistened with the *clear* mercurial solution, and touched through the liquid with a piece of iron, contracts a

white stain. This test, which was proposed by Mr. Sylvester and simplified by Dr. Paris, is conveniently applied by moistening, with the suspected solution, a gold coin or ring, and touching it through the moistened spot with the point of a penknife. The object of the iron is to form with the gold a simple galvanic circle, which enables the latter metal to precipitate the mercury on its surface. Nearly all the above tests merely prove the presence of mercury. To determine whether the metal is united with chlorine, the mercurial liquid may be precipitated by lime-water, and the filtered solution, acidulated with nitric acid, then tested with nitrate of silver. If the mercury is in the state of chloride, the filtered solution will be one of chloride of calcium, which, with nitrate of silver, will yield a heavy white precipitate (chloride of silver), insoluble in nitric acid, but soluble in ammonia. The nitrate of silver may be added directly to the mercurial liquid; and, if it contain corrosive sublimate, chloride of silver will fall, but probably mixed with calomel.

By the combined indications of the foregoing tests, corrosive sublimate may be infallibly detected, unless it exists in very minute quantity, associated with organic substances, by which its presence is often greatly obscured. When it exists in organic mixtures, made by boiling the contents or substance of the stomach in distilled water, Dr. Christison recommends that a preliminary trial be made with the protochloride of tin, on a small portion filtered for the purpose. If this causes a grayish-black colour, he shakes the mixture, as recommended by Orfila, with a fourth of its bulk of cold ether, which dissolves the corrosive sublimate, and rises to the surface. The ethereal solution is then evaporated to dryness, and the dry salt obtained is dissolved in hot water, whereby a pure solution is procured, in which the poison may be readily detected by the ordinary tests. In using ether, however, it must be borne in mind that, as ascertained by M. Mialhe, the presence of a considerable quantity of deutoxide of mercury, and of a chloride of an alkalifiable metal, prevents the solvent power of ether. If the trial test should produce a light-gray colour, the corrosive sublimate is indicated in still less quantity, and Dr. Christison recommends to proceed in the following manner. Treat the unfiltered mixture with protochloride of tin, as long as any precipitate is formed, which will have a slate-gray colour. Collect, wash, and drain it on a filter, and, having removed it without being dried, boil it, in a glass flask, with a moderately strong solution of caustic potassa, until all the lumps disappear. The alkali will dissolve all animal and vegetable matter; and, on allowing the solution to remain at rest, a heavy grayish-black powder will subside, which consists chiefly of metallic mercury, and in which small globules of the metal may sometimes be seen with the naked eye, or by the aid of a magnifier. Probably advantage might be derived from the process of dialysis, in separating corrosive sublimate, among other crystallizable substances, from the colloidal matters contained in organic mixtures. (See *Dialysis*, p. 896.)

Off. Prep. Hydrargyri Iodidum Rubrum; Hydrargyrum Ammoniatum. B.

HYDRARGYRI CHLORIDUM MITE. *U. S.* Calomelas. *Br. Mild Chloride of Mercury. Calomel.*

"Take of Mercury *forty-eight troyounces;* Sulphuric Acid *thirty-six troyounces;* Chloride of Sodium *eighteen troyounces;* Distilled Water *a sufficient quantity.* Boil, by means of a sand-bath, twenty-four troyounces of the Mercury with the Sulphuric Acid, until a dry white mass is left. Rub this, when cold, with the remainder of the Mercury, in an earthenware mortar, until they are thoroughly mixed. Then add the Chloride of Sodium, and, having rubbed it with the other ingredients until globules of Mercury cease to be visible, sublime the mixture. Reduce the sublimed matter to a very fine powder, wash it with boiling Distilled Water, until the washings afford no precipitate with water of ammonia, and dry it." *U. S.*

"Take of Sulphate of Mercury *ten ounces* [avoirdupois]; Mercury *seven*

ounces [avoird.]; Chloride of Sodium, dried, *five ounces* [avoird.]; Boiling Distilled Water *a sufficiency*. Moisten the Sulphate of Mercury with the Water, and rub it and the Mercury together until globules are no longer visible; add the Chloride of Sodium, and thoroughly mix the whole by continued trituration. Sublime by a suitable apparatus into a chamber of such size that the Calomel, instead of adhering to its sides as a crystalline crust, shall fall as a fine powder on its floor. Wash this powder with boiling Distilled Water, until the washings cease to be darkened by a drop of hydrosulphuret of ammonia. Finally, dry at a heat not exceeding 212°, and preserve in a jar or bottle impervious to light." *Br.*

The object of the above processes is to obtain the protochloride of mercury. This chloride consists of one eq. of chlorine and one of mercury, and consequently contains precisely half as much chlorine as corrosive sublimate, combined with the same quantity of mercury. In the U. S. process, as in the case of corrosive sublimate, a bisulphate of the deutoxide is first formed; but, instead of being immediately sublimed with the chloride of sodium, it undergoes a preparatory trituration with a quantity of mercury equal to that employed in forming it. This trituration may be conceived to take place between one eq. of bisulphate of the deutoxide, and one of metallic mercury, which are thus converted into two eqs. of monosulphate of the protoxide. This change will be easily understood, by adverting to the fact, that the bisulphate of the deutoxide consists of two eqs. of sulphuric acid, two of oxygen, and one of mercury; and, when rubbed up with one additional eq. of mercury, the whole becomes two eqs. of acid, two of oxygen, and two of mercury, evidently corresponding with two eqs. of monosulphate of the protoxide. The two eqs. of monosulphate thus formed, being heated with two of common salt, the two eqs. of chlorine in the latter sublime in union with the two of mercury in the former, and generate two eqs. of protochloride of mercury; while the two eqs. severally, of sulphuric acid, oxygen, and sodium, unite together to form two of dry sulphate of soda, which remain as a fixed residue. It is hence apparent that the residue of this process and of that for corrosive sublimate is the same.

The calomel in mass, as sublimed, is liable to contain a little corrosive sublimate; and hence the direction of the U. S. Pharmacopœia to reduce the sublimed matter to a very fine powder, and to wash it with boiling distilled water until ammonia produces no precipitate with the washings. Ammonia occasions a white precipitate (ammoniated mercury) so long as the washings contain corrosive sublimate; and, when it ceases to produce this effect, the operator may rest satisfied that the whole of the poisonous salt has been removed. According to M. Berthé, calomel, in contact with hot water, is converted, to a small extent, into corrosive sublimate; and hence he recommends that the portion of water to be tested should be cold when passed through the calomel.

The British process is a modification of that of the late Dublin Pharmacopœia, including, like that, no directions for making the bisulphate of the deutoxide of mercury; because this salt is made by a separate formula, being designated as *sulphate of mercury*. It omits, however, as unnecessary, a partial preliminary sublimation, directed by the Dublin College, to test the production of corrosive sublimate, and, immediately after a thorough mixture of the materials, proceeds to the final sublimation. A special proceeding, in which the Dublin process is followed, is to cause the vapours to enter for condensation a chamber of considerable size, so that they may fall in powder, instead of condensing on the sides of the receiver in a crystalline mass. The necessity of pulverizing the calomel is thus avoided. As our own, the Br. Pharmacopœia directs the powder to be washed; but, instead of using ammonia as a test of the absence of corrosive sublimate in the washings, directs for the purpose hydrosulphuret of ammonia, which throws down a black precipitate if corrosive sublimate is present.

Preparation on the Large Scale. The process for making calomel, by means of the bisulphate of deutoxide of mercury, was originally practised at Apothecaries' Hall, London. The proportions taken and the mode of proceeding in that establishment are, according to Mr. Brande, as follows: 50 lbs. of mercury are boiled to dryness with 70 lbs. of sulphuric acid, in a cast-iron vessel; and 62 lbs. of the dry salt formed are triturated with 40½ lbs. of mercury till the globules disappear, and the whole is mixed with 34 lbs. of common salt. The mixture is sublimed from an earthenware retort into an earthenware receiver, and the product is from 95 to 100 lbs. of calomel in mass. This is then ground to an impalpable powder, and washed with a large quantity of distilled water.

The object of bringing calomel into a state of minute division is more perfectly accomplished by the method of Mr. Joseph Jewell, of London, improved by M. Ossian Henry. It consists in causing the calomel in vapour to come in contact with steam in a large receiver, whereby it is condensed into an impalpable powder, and perfectly washed from corrosive sublimate in the same operation. Calomel made by this process, sometimes called Jewell's or Howard's *hydrosublimate of mercury*, is free from all suspicion of containing corrosive sublimate, is much finer than when obtained by levigation and elutriation, and possesses more activity as a medicine. This kind of calomel is included in the French Codex under a distinct name (*mercure doux à la vapeur*). M. Soubeiran, of Paris, has perfected a process for obtaining calomel as an impalpable powder, by substituting the agency of cold air for that of steam for the purpose of condensing it; a process which he believes to be precisely the same as that pursued by the English manufacturers, and which produces a calomel equal to the best English. A description of his apparatus may be found in the *Journal de Pharmacie* (3*e sér.*, ii. 507), and of the English apparatus, as described by F. C. Calvert, in the same journal (3*e sér.*, iii. 121). Both these papers are copied into the *Am. Journ. of Pharm.* (xv. 89 and 93).

Prof. Wöhler has proposed to obtain calomel, in the humid way, by precipitating a solution of corrosive sublimate by a stream of sulphurous acid, taking advantage of a reaction first observed by Vogel. Calomel, obtained in the humid way, called *precipitated calomel*, was formerly officinal with the Dublin College, and is still retained in the French Codex. This form of calomel is of doubtful utility; and, when obtained by Prof. Wöhler's process, it is a crystalline powder, which is a fatal objection to it.

Properties. Mild chloride of mercury is a tasteless, inodorous substance, insoluble in water, alcohol, and ether, less volatile than corrosive sublimate, unalterable in the air, but blackening by long exposure to the light. When in mass its form and appearance depend on the shape and temperature of the subliming vessel. In this state it is generally in the form of a white, fibrous, crystalline cake, the interior surface of which is often studded with shining transparent crystals, having the shape of quadrangular prisms, and a texture somewhat horny and elastic. When the mass is scratched it yields a yellow streak, which is very characteristic. Its sp. gr. is 7·2. The officinal form of this chloride is that of powder, in which state it is always kept in the shops. The powder has a light buff or ivory colour, if obtained by the levigation of sublimed masses; but if condensed at once in the form of an impalpable powder, as is the case with Jewell's calomel, it is perfectly white. To protect it from the action of the light, it should be kept in a dark place, or in bottles painted black, or covered with black paper. By the action of the fixed alkalies or alkaline earths it immediately becomes black, in consequence of the formation of protoxide, reducible by heat to the metallic state. The preparation employed under the name of *lotio nigra* or *black wash*, as a local application to syphilitic ulcers, &c., is made by adding *a drachm* of calomel to *a pint* of lime-water. By double decomposition between the calomel and lime, the black protoxide precipitates, and chloride of calcium

remains in solution, indicated by yielding a copious white precipitate with nitrate of silver. The oxide, however, is not pure, but associated with undecomposed calomel. Before being applied, the wash should be well shaken.

Tests of Purity and Incompatibles. Calomel, when pure, completely sublimes on the application of heat, a property which detects all fixed impurities, such as carbonate, sulphate, and phosphate of lime, sulphate of baryta, and carbonate of lead. Under the influence of an elevated temperature, especially in the presence of alcohol or water, it gives rise to a small quantity of corrosive sublimate. (*M. Berthé.*) Calomel strikes a black colour, free from reddish tinge, by the action of the fixed alkalies; and the black oxide thus produced is brought by heat to the metallic state. The buff colour indicates the absence of corrosive sublimate; but whiteness by no means shows the presence of this impurity. Its freedom from the corrosive chloride may be determined by washing a portion of it in warm distilled water, and then testing the water with ammonia, which will cause a white precipitate (ammoniated mercury), should the water have taken up any of the poisonous chloride. The presence of any chloride whatever in the calomel would be detected by the production of a precipitate with the washing by nitrate of silver. Soluble salts of mercury may be detected by rubbing the suspected calomel with ether on a bright surface of copper, when the metal will become amalgamated, and exhibit a white stain. When this test shows impurity, the soluble salt present is probably corrosive sublimate. Calomel, containing corrosive sublimate, acts violently on the bowels; and, when the impurity has been present in considerable amount, has been known to cause death. Besides being incompatible with the alkalies and alkaline earths, calomel is also decomposed by the alkaline carbonates, soaps, hydrosulphates, and, according to some authorities, by iron, lead, and copper. By boiling with the alkaline formiates it is decomposed, and metallic mercury liberated. (H. Rose, *Annal. der Physik und Chem.*, cvi. 500.) According to M. Lebeaux, calomel should not be prescribed with iodine; unless the prescriber intends to give biniodide (red iodide) of mercury, when the dose must be reduced accordingly. (*Annuaire de Thérap.*, 1857, p. 180.) It should not be given at the same time with nitromuriatic acid, for fear of generating corrosive sublimate. One of the authors has been informed of a case, in which death, with symptoms of violent gastro-intestinal irritation, followed their simultaneous use. Agreeably to the experiments of M. Deschamps, calomel is decomposed by bitter almonds and by hydrocyanic acid. In the former case corrosive sublimate, bicyanide of mercury, and muriate of ammonia are formed; in the latter, corrosive sublimate and bicyanide only. Hence this writer considers it very dangerous to associate calomel with bitter almonds or hydrocyanic acid in prescription. This conclusion has been confirmed by M. Mialhe and M. Prenleloup; and, more recently, it has been shown by Dr. E. Riegel that cherry-laurel water has the power of converting calomel into corrosive sublimate. According to M. Mialhe, calomel is in part converted into corrosive sublimate and metallic mercury by muriate of ammonia, and by the chlorides of sodium and potassium, even at the temperature of the body; and hence he believes that the conversion may take place in the primæ viæ. Popular belief coincides with M. Mialhe's views in regard to the power of common salt to increase the activity of calomel. More recently M. Mialhe has extended his observations, and now believes that all the preparations of mercury yield a certain amount of corrosive sublimate by reacting with solutions of the chlorides of potassium, sodium, and ammonium. The deutoxide and similarly constituted compounds are most prone to undergo this change. Even metallic mercury, digested with the chlorides named, is partly converted, under the influence of the air, into corrosive sublimate. Dr. Gardner denies the assertion of M. Mialhe, that calomel is converted into corrosive sublimate by chlorides of the alkalifiable metals, maintaining that it is merely rendered soluble by their solutions. The

results, however, of M. Mialhe have been confirmed experimentally by Dr. A. Fleming, of Pittsburg, Pa. (*Am. Journ. of Pharm.*, Sept. 1857.) M. Bauwens of Ghent, recognising the conversion of calomel into corrosive sublimate in the body by these chlorides, explains by this fact the relatively less powerful action of large than of small doses of calomel. He also states that physicians near the sea, where the water is brackish, seldom prescribe calomel, and that naval surgeons have been obliged to abstain from giving it to sailors who eat salt meat. Dr. H. Peake of Arkadelphia, Arkansas, has known many instances in which salivation has been induced by the joint use of calomel and vegetable acids, in the forms of sour fruit, vinegar, buttermilk, &c., where the mercurial alone would not have induced it. (*N. O. Med. and Surg. Journ.*, Nov. 1858, p. 724.) B.

Medical Properties and Uses. Calomel unites to the general properties of the mercurials those of a purgative and anthelmintic. It is the most valuable of the mercurial preparations, and in extent of employment is inferior to few articles of the Materia Medica. Whether the object is to bring the system under the general influence of mercury, or to produce its alterative action upon the hepatic or other secretory function, calomel, on account both of its certainty and mildness, is preferred to all other preparations, with the single exception of the blue pill, which, though less certain, is still milder, and is sometimes preferably employed. When used with the above objects, the tendency to purge which it sometimes evinces, even in very small doses, must be restrained by combining it with opium. In sialagogue or alterative doses, it is often prescribed with other medicines, which, while they give it a direction to certain organs, have their own peculiar influence increased by its co-operation. Thus it renders squill more diuretic, nitre and the antimonials more diaphoretic, and seneka more expectorant.

As a purgative, calomel owes its chief value to its tendency to the liver, the secretory function of which it powerfully stimulates. It is usually slow and somewhat uncertain in its cathartic effect, and, though itself but slightly irritating, sometimes occasions severe griping pain with bilious vomiting, attributable to the acrid character of the bile which it causes the liver to secrete. It is peculiarly useful in the commencement of bilious fevers, in hepatitis, jaundice, bilious and painters' colic, dysentery, especially that of tropical climates, and all other affections attended with congestion of the portal system, or torpidity of the hepatic function. The difficulty with which it is thrown from the stomach, renders it highly useful in some cases of obstinate vomiting, when other remedies are rejected. In the cases of children it is peculiarly valuable from the facility of its administration; and, in the febrile complaints to which they are subject, appears to exercise a curative influence, depending on some other cause than its mere purgative effect, and perhaps referrible to its action upon the liver. In the treatment of worms it is one of the most efficient remedies, acting probably not only as a purgative, but also as an irritant to the worms, either by its immediate influence, or that of the acrid bile which it causes to flow. The slowness and uncertainty of its action, and its liability to salivate if too long retained in the bowels, render it proper either to follow or combine it with other cathartics, in order to ensure its purgative effect. When given alone, it should be followed, if it do not operate in six or seven hours, by a dose of castor oil or sulphate of magnesia. The cathartics with which it is most frequently combined are jalap, rhubarb, aloes, scammony, colocynth, and gamboge. It is often added in small quantities to purgative combinations, with a view to its influence on the liver.

In very large doses, calomel is supposed by some to act directly as a sedative, and with this view has been given in yellow and malignant bilious fevers, violent dysentery, malignant cholera, &c. The quantities which have been administered in such affections, with asserted impunity and even advantage, are almost incredible. A common dose is one or two scruples, repeated every half

hour, or hour, or less frequently, according to the circumstances of the case. We have had no experience in this mode of administering calomel.

It is sometimes used as an errhine in amaurosis, mixed with twice its weight of sugar, or other mild powder; and in the same combination is occasionally employed to remove specks and opacity of the cornea. For the latter purpose, Dupuytren recommended particularly the calomel prepared according to the plan of Mr. Jewell. Calomel is also sometimes employed externally in herpetic and other eruptions, in the shape of an ointment.

The dose as an alterative, in functional derangement of the liver, is from half a grain to a grain every night, or every other night, followed in the morning, if the bowels are not opened, by a gentle saline laxative. When the stomach or bowels are very irritable, as in cholera and diarrhœa, from an eighth to a quarter of a grain may be given every hour or two, so as to amount to one or two grains in the course of the day. With a view to salivation, the dose is from half a grain to a grain three or four times a day, to be increased considerably in urgent cases. Sometimes, very minute doses, as the twelfth of a grain or less, given very frequently, so as to amount to the ordinary quantity in twenty-four hours, will operate more effectually as a sialagogue than larger doses. When large doses are given with this view, it is often necessary to combine them with opium. As a purgative, from five to fifteen grains or more may be exhibited. Calomel has the peculiarity that its cathartic action is not increased in proportion to the dose, and enormous quantities have been given with impunity. In yellow fever, tropical dysentery, &c., from twenty grains to a drachm have been given, and repeated at short intervals, without producing hypercatharsis; but this practice is justifiable only in cases of extreme urgency, in which the constitutional action of mercury as well as purgation is indicated. Even in very small doses of not more than one, two, or three grains, calomel purges some individuals briskly. In these persons, large doses, though they do not proportionably increase the evacuation, often occasion spasmodic pain in the stomach and bowels. For children larger doses are generally required in proportion than for adults. Not less than from three to six grains should be given as a purge to a child two or three years old; and this quantity often fails to act, unless assisted by castor oil or some other cathartic. Calomel may be given in pill made with gum arabic and syrup, or in powder mixed with syrup or molasses.

W.

HYDRARGYRI CYANIDUM. *U. S.* Hydrargyri Cyanuretum. *U. S.* 1850. *Cyanide of Mercury. Cyanuret of Mercury. Bicyanide of Mercury. Prussiate of Mercury.*

"Take of Ferrocyanide of Potassium *five troyounces;* Sulphuric Acid *four troyounces and one hundred and twenty grains;* Red Oxide of Mercury, in fine powder, Water, each, *a sufficient quantity.* Dissolve the Ferrocyanide of Potassium in twenty fluidounces of Water, and add the solution to the Sulphuric Acid, previously diluted with ten fluidounces of Water, and contained in a glass retort. Distil the mixture nearly to dryness into a receiver, containing ten fluidounces of Water and three troyounces of Red Oxide of Mercury. Set aside two fluidounces of the distilled liquid, and to the remainder add, with agitation, sufficient Red Oxide to destroy the odour of hydrocyanic acid. Then filter the solution, and, having added the reserved liquid, evaporate the whole in a dark place, in order that crystals may form. Lastly, dry the crystals, and keep them in a well-stopped bottle, protected from the light." *U. S.*

This is an entirely different formula from that of the Pharmacopœia of 1850, in which the ferrocyanide of iron and red oxide of mercury were brought together under circumstances favourable to reaction, with the result of produc-

ing bicyanide of mercury, the protoxide and sesquioxide of iron, and an undetermined compound of cyanogen. The present formula is based upon that of Winkler, given in the eleventh edition of the U. S. Dispensatory. Hydrocyanic acid is generated by the action of sulphuric acid on the ferrocyanide of potassium, and, being received in a vessel containing water and a portion of red oxide of mercury, reacts with the oxide, generating, by double decomposition, water, and bicyanide of mercury which is held in solution. The reaction takes place between one equivalent of the red oxide of mercury which is a binoxide, and two eqs. of hydrocyanic acid. The two eqs. of oxygen of the binoxide take two eqs. of hydrogen of the acid to form two eqs. of water, and the two liberated eqs. of cyanogen combine with the single liberated eq. of mercury to form the bicyanide of that metal. Sufficient red oxide of mercury is not used at first to saturate the whole of the hydrocyanic acid generated, because, should there happen to be any excess of the red oxide, there would be produced on evaporation, instead of the substance wanted, a peculiar salt composed of bicyanide and red oxide of mercury, which would crystallize in small acicular crystals. Hence, a portion of the water still containing uncombined hydrocyanic acid is set aside, to be added to the liquid in which the acid had been completely saturated by the addition of red oxide, and thus at least neutralize any oxide of mercury that might be present in it in excess. A surplus of hydrocyanic acid would be of no disservice, except the loss of material incurred, as it is evaporated in the subsequent concentration.

Properties, &c. Cyanide of mercury is permanent in the air, and crystallizes in anhydrous right square prisms, which are sometimes transparent, but usually white and opaque. It has a disagreeable styptic taste. It is but sparingly soluble in alcohol, but dissolves readily in cold water, and much more abundantly in hot. When acted on by muriatic acid, hydrocyanic acid is evolved, recognisable by its odour, and bichloride of mercury is left, which is wholly volatilizable by heat. When heated it yields cyanogen, and a black matter is left containing globules of mercury.

In composition, according to the view taken in the U. S. Pharmacopœia, it is a bicyanide of mercury, consisting of one eq. of the metal 200, and two of cyanogen $52 = 252$; its formula being $HgCy_2$. But with those who consider the eq. of mercury as 100, the salt is a protocyanide, with one eq. of each of its constituents (HgCy), and its combining number would be 126. The reader is already aware that the former opinion is still admitted in this work.

Cyanide of mercury acts on the animal economy as a potent poison. In medicinal doses it sometimes causes ptyalism, but does not produce epigastric pain like corrosive sublimate. It has been occasionally used as a remedy in syphilis; and in the treatment of that disease it is preferred by some practitioners to corrosive sublimate, on account of its not giving rise to pain, and not being decomposed by alkalies and organic substances. M. Desmartis, of Bordeaux, considers it superior to all the other preparations of mercury in the treatment of syphilitic complaints; particularly in cases in which the patients have suffered, for a long period, from obscure pains. The dose is from the sixteenth to the eighth of a grain, which should not be exceeded; as the medicine may meet with free muriatic acid in the stomach. B.

HYDRARGYRI IODIDUM RUBRUM. *U. S., Br. Red Iodide of Mercury. Biniodide of Mercury.*

"Take of Corrosive Chloride of Mercury *a troyounce* Iodide of Potassium *a troyounce and one hundred and twenty grains;* Distilled Water *a sufficient quantity.* Dissolve the Chloride of Mercury in a pint and a half, and the Iodide of Potassium in half a pint of Distilled Water, and mix the solutions. Collect the precipitate upon a filter, and, having washed it with Distilled Water, dry it with a gentle heat, and keep it in a well-stopped bottle." *U. S.*

"Take of Corrosive Sublimate *four ounces* [avoirdupois]; Iodide of Potassium *five ounces* [avoird.]; Boiling Distilled Water *four pints* [Imperial measure]. Dissolve the Corrosive Sublimate in three pints [Imp. meas.], and the Iodide of Potassium in the remainder of the Water, and mix the two solutions. When the temperature of the mixture has fallen to that of the atmosphere, decant the supernatant liquor from the precipitate, and, having collected the latter on a filter, wash it twice with cold distilled water, and dry it at a temperature not exceeding 212°." *Br.*

In the above processes for forming biniodide of mercury, which may be considered as identical, a double decomposition takes place between corrosive sublimate and iodide of potassium, resulting in the formation of chloride of potassium which remains in solution, and biniodide of mercury which precipitates. The precipitate is soluble in the reacting salts, and hence a loss of part of it is incurred by an excess of either. It is best, however, to have a slight excess of the iodide of potassium, which is furnished by the proportion taken in the formulas; as then the decomposition of the whole of the corrosive sublimate is ensured, and any contamination of the biniodide by it prevented. The late process of the Edinburgh College consisted in a combination of the ingredients by trituration in due proportion with the aid of alcohol; but, after the red powder was obtained, it was treated with a boiling solution of common salt, which dissolved the biniodide to the exclusion of any contaminating protiodide; and the solution, thus obtained, on cooling, deposited the pure biniodide in crystals.

Properties. Biniodide of mercury is a scarlet-red powder, of the sp. gr. 6·3, insoluble in water, sparingly soluble in alcohol, freely so in ether, and soluble in muriatic acid and in solutions of iodide of potassium, chloride of sodium, and many of the mercurial salts. As obtained by the late Edinburgh process, it is in splendid crimson acicular crystals. When heated it fuses readily into a yellow liquid, and sublimes in yellow rhombic scales, which become red on cooling. Biniodide of mercury is a dimorphous substance, having a different crystalline form in its red and yellow states. According to Schiff, it is only in its yellow form that it is soluble in alcohol; and hence it is that, when separated by water from its alcoholic solution, it falls in this condition. (*Ann. der Chem. und Pharm.*, cix. 371.) It forms definite compounds with the iodides of the alkaliflable metals. The compound formed with iodide of potassium has been used as a medicine. (See *Iodohydrargyrate of Potassium*, in Part III.) Biniodide of mercury consists of one eq. of mercury 200, and two of iodine 252·6 = 452·6, and its formula is HgI_2. In the Br. Pharmacopœia, which recognises 100 as the eq. of mercury, it is considered as the neutral iodide, with the formula HgI. It combines with the protiodide, so as to form a yellow *sesquiodide*, represented by the formula $HgI + HgI_2$ or Hg_2I_3.

Medical Properties and Uses. Biniodide of mercury is a powerful irritant poison. It has been used in similar diseases with the protiodide, namely, in scrofula and syphilis, but is much more active. Dr. Fuller, physician to St. George's Hospital, London, has found it a valuable remedy in rheumatism, dependent on a syphilitic taint, having cured several cases in which corrosive sublimate had been given in vain. He also employed it with good results in two cases of epilepsy, dependent on injuries to the head, in which he suspected thickening of the dura mater, or deposit between it and the bone. (*Ranking's Abstract*, No 25, p. 51.) The dose of this iodide is the sixteenth of a grain, gradually increased to the fourth, given in pill or dissolved in alcohol. A preferable mode of administering it, is dissolved in a solution of iodide of potassium. This mode was adopted by Dr. Fuller, who attributes his success with the remedy, in great measure, to its having been given in this way. The preparation thus made is really a solution of iodohydrargyrate of potassium.

M. Cazenave considers biniodide of mercury as the best topical application in

lupus. He applies it in thin layers, every six or eight days, to small portions of the ulcerated surface at a time, in the form of a caustic ointment, made of equal parts of the iodide, oil, and lard. The application produces severe pain, and gives rise to a sharp inflammation which soon terminates, leaving the ulcer in an improved condition, with a tendency to cicatrize smoothly, and on a level with the surrounding skin. (*Ann. de Thérap.*, 1852, p. 175.)

HYDRARGYRI IODIDUM VIRIDE. *U. S., Br.* HYDRARGYRI IODIDUM. *U. S.* 1850. *Green Iodide of Mercury. Protiodide of Mercury. Iodide of Mercury.*

"Take of Mercury *a troyounce;* Iodine *three hundred grains;* Stronger Alcohol *a sufficient quantity.* Mix the Mercury and Iodine in a mortar, and, having added half a fluidounce of Stronger Alcohol, triturate the mixture until the ingredients are thoroughly incorporated. Stir the mixture occasionally, and, at the end of two hours, triturate again, with considerable pressure, until it is nearly dry. Then rub it up with Stronger Alcohol, gradually added, until it is reduced to a uniform thin paste; and, having transferred this to a filter, wash it with Stronger Alcohol until the washings cease to produce a permanent cloudiness when dropped into a large quantity of water. Lastly, dry the Iodide in the dark with a gentle heat, and keep it in a well-stopped bottle, protected from the light." *U. S.*

"Take of Mercury, by weight, *one ounce* [avoirdupois]; Iodine *two hundred and seventy-eight grains;* Rectified Spirit *a sufficiency.* Rub the Iodine and Mercury in a porcelain mortar, occasionally moistening the mixture with a few drops of the Spirit, and continue the trituration until metallic globules are no longer visible, and the whole assumes a green colour. The product thus obtained should be dried in a dark room, on filtering paper, by simple exposure to the air, and preserved in an opaque bottle." *Br.*

This process for forming the protiodide of mercury is a case of simple combination, the alcohol facilitating the union by dissolving the iodine. It may also be prepared by precipitation, by adding a solution of iodide of potassium to one of nitrate of protoxide of mercury; but, as it is difficult to prepare the nitrate of the protoxide, without being mixed with some binitrate of deutoxide, the protiodide, when thus obtained, is apt to be contaminated with biniodide. M. Roland Seeger suggests double decomposition between protacetate of mercury and iodide of potassium. (*Am. Journ. of Pharm.*, May, 1859, p. 204.) M. Boutigny proposes to decompose calomel by iodide of potassium, and gives the following formula. Twenty-nine drachms of calomel are mixed with twenty of pulverized iodide of potassium in a glass mortar, and twelve ounces of boiling distilled water poured upon the mixture. After cooling the liquid is decanted, and the precipitate washed on a filter with distilled water, and dried in the shade. (See *Am. Journ. of Pharm.*, viii. 326.) This process did not succeed with Mr. Charles Bullock, of this city, when he used the reacting ingredients in quantities six times those recommended by M. Boutigny. Mr. John Canavan, of New York, ascribes the failure to insufficient trituration, which, to ensure complete reaction, must be long continued. If the reaction be imperfect, the water washes away not only chloride of potassium, but also iodide of potassium, holding in solution a part of the protiodide of mercury formed, which is ultimately decomposed into biniodide and metallic mercury. The experiments of Mr. J. M. Maisch, of this city, tend to confirm this view. He further found that a boiling temperature enables chloride of potassium to decompose the protiodide perceptibly, and infers that the use of cold water would give a purer product. He, therefore, concludes that the process of Boutigny cannot be depended upon for giving a pure protiodide, and that we must fall back on the Pharmacopœia process. As prepared by the

U. S. formula of 1850, it was liable to contain a little biniodide; but this is obviated in the present edition by the direction to wash it, near the close of the operation, with stronger alcohol. It is known to be free from the biniodide when the alcoholic washings produce no permanent cloudiness with a large quantity of water. Even thus purified, however, it generally contains a little metallic mercury, and, according to Dr. Squibb, a considerable proportion of the yellow or subiodide; but these are of little consequence compared with the biniodide, which should always be carefully sought for, and separated if found. (See Mr. Maisch's paper, *Am. Journ. of Pharm.*, Jan. 1857.)

Properties. Iodide of mercury is in the form of a greenish-yellow powder, insoluble in water, alcohol, and solution of chloride of sodium, but soluble in ether. Its sp. gr. is 7·75. When exposed to the light it is partially decomposed, and becomes of a dark-olive colour. If quickly and cautiously heated, it sublimes in red crystals which afterwards become yellow. It is a protiodide of mercury HgI, consisting of one eq. of mercury 200, and one of iodine 126·3 = 326·3. The Br. Pharmacopœia considers it a subiodide, with the formula Hg_2I; the eq. of mercury being 100.

Medical Properties and Uses. Iodide of mercury has been given in scrofula and scrofulous syphilis. The dose is a grain daily, gradually increased to three or four grains. It should never be given at the same time with iodide of potassium, which converts it immediately into biniodide and metallic mercury. (Mialhe, *Journ. de Pharm.*, 3e *sér.*, iv. 36.) B.

HYDRARGYRI OXIDUM RUBRUM. *U. S.*, *Br.* *Red Oxide of Mercury. Red Precipitate.*

"Take of Mercury *thirty-six troyounces;* Nitric Acid *twenty-four troyounces;* Water *two pints;* Dissolve the Mercury, with the aid of a gentle heat, in the Acid and Water previously mixed, and evaporate to dryness. Rub the dry mass into powder, and heat it in a very shallow vessel until red vapours cease to rise." *U. S.*

"Take of Mercury, by weight, *eight ounces* [avoirdupois]; Nitric Acid *three fluidounces;* Water *two fluidounces.* Dissolve half the Mercury in the Nitric Acid diluted with the Water, evaporate the solution to dryness, and with the dry salt thus obtained, triturate the remainder of the Mercury until the two are uniformly blended together. Heat the mixture in a porcelain capsule, with repeated stirring, until acid vapours cease to be evolved, and, when cold, enclose the product in a bottle." *Br.*

In these processes the mercury is first oxidized at the expense of a portion of the nitric acid, the remainder of which unites with the oxidized metal to form either nitrate of deutoxide of mercury, or a mixture of this with nitrate of the protoxide. The resulting mass when exposed to a strong heat is decomposed, giving out red nitrous fumes, and assuming successively a yellow, orange, and brilliant purple-red colour, which becomes orange-red on cooling. These changes are owing to the gradual separation and decomposition of the nitric acid, by the oxygen of which the protoxide of mercury, if any be present, is converted into deutoxide, while nitric oxide gas escapes, and becomes hyponitric acid vapour on contact with the air. The deutoxide of mercury is left behind; but in general not quite free from the nitrate, which cannot be wholly decomposed by heat, without endangering the decomposition of the oxide itself, and the volatilization of the metal. The preparation is commonly called *red precipitate.* The name of *red oxide of mercury*, by which it is now designated in most of the Pharmacopœias, is appropriate, as nitrate of mercury exists in it merely as an accidental impurity; and there is no occasion to distinguish the preparation from the pure deutoxide obtained by calcining mercury, the latter not being officinal, and perhaps never employed.

In the preparation of this mercurial, various circumstances influence the

nature of the product, and must be attended to, if we desire to procure the oxide with that fine bright orange-red colour, and shining scaly appearance, usually considered desirable. Among these circumstances is the condition of the nitrate of mercury submitted to calcination. According to Gay-Lussac, it should be employed in the form of small crystalline grains. If previously pulverized, as directed in the officinal processes, it will yield an orange-yellow powder; if it be in the state of large and dense crystals, the oxide will have a deep-orange colour. Care must also be taken that the mercury and acid be free from impurities. It is highly important that sufficient nitric acid be employed fully to saturate the mercury. M. Payssé, who paid great attention to the manufacture of red precipitate, recommended 70 parts of nitric acid from 34° to 38° Baumé, to 50 parts of mercury. This, however, is an excess of acid. We have been told by a skilful practical chemist of Philadelphia that he has found, by repeated experiment, 7 parts of nitric acid of 35° Baumé, to be sufficient fully to saturate 6 parts of mercury. Less will not answer, and more would be useless. It is not necessary that the salt should be removed from the vessel in which it is formed; and it is even asserted that the product is always more beautiful when the calcination is performed in the same vessel. A matrass may be used with a large flat bottom, so that an extended surface may be exposed, and all parts heated equally. The metal and acid having been introduced, the matrass should be placed in a sand-bath, and covered with sand up to the neck. The solution of the mercury should be favoured by a gentle heat, which should afterwards be gradually increased till red vapours appear, then maintained as equably as possible till these vapours cease, and at last slightly elevated till oxygen gas begins to escape. This may be known by the increased brilliancy with which a taper will burn if placed in the mouth of the matrass, or by its rekindling if partially extinguished. Too high a temperature must be carefully avoided, as it decomposes the oxide, and volatilizes the mercury. At the close of the operation, the mouth of the vessel should be stopped, and the heat gradually diminished, the matrass being still allowed to remain in the sand-bath. These last precautions are said to be essential to the fine red colour of the preparation. It is best to operate upon a large quantity of materials, as the heat may be thus more uniformly maintained. The direction in the British, taken from the late Ed. Pharmacopœia, to rub a portion of mercury with the nitrate before decomposing it, renders the process more economical; as the nitric acid, which would otherwise be dissipated, is thus employed in oxidizing an additional quantity of the metal.

As the process is ordinarily conducted in laboratories, the nitrate of mercury is decomposed in shallow earthen vessels, several of which are placed upon a bed of sand, in the chamber of an oven or furnace, provided with a flue for the escape of the vapours. Each vessel may conveniently contain ten pounds of the nitrate. There is always loss in the operation thus conducted.

Under the name of *Hydrargyri Oxydum Rubrum*, the Dublin College formerly directed a preparation, called by the elder chemists *hydrargyrum præcipitatum per se*, or *precipitate per se*, and sometimes *calcined mercury*, made by exposing the metal to a heat near its boiling point, or about 600° F., in a matrass with a broad bottom and narrow mouth. The vapours rising were condensed in the upper part of the vessel; and a circulation was thus kept up within it, during which the mercury slowly combined with oxygen, being converted first into a black and then into a red powder. But the process was very slow, requiring several weeks for the complete oxidization of the metal; and, as the product, which was pure deutoxide, had no peculiar virtues to recommend it over the oxide procured in the ordinary mode, it was properly discarded by the College. The oxide made in this way is in minute, sparkling, crystalline scales, of a deep-red colour, becoming still deeper by heat.

The same oxide of mercury, prepared by precipitation, was recognised in a

former London Pharmacopœia by the name of *Hydrargyri Binoxidum*, or *binoxide of mercury*. It was made by adding solution of potassa in excess to a solution of bichloride of mercury, and differed from the preceding only in containing some water. It was an orange-red, impalpable powder, having the same properties essentially as the present officinal red oxide.

Properties, &c. Red precipitate, well prepared, has a brilliant red colour, with a shade of orange, a shining scaly appearance, and an acrid taste. It is very slightly soluble in water, of which Dr. Barker found 1000 parts to take up 0·62 of the oxide. Dr. Christison found 1 part of the oxide to be dissolved by about 7000 parts of boiling water, and the solution to give a black precipitate with sulphuretted hydrogen. Tannic acid precipitates metallic mercury from its aqueous solution, especially when heated. (Bullock, *Proceed. of Am. Pharm. Assoc.*, 1858, p. 306.) It is insoluble in cold alcohol and ether. (*Ibid.*) Nitric and muriatic acids dissolve it without effervescence. It yields oxygen when heated, and at a red heat is decomposed and entirely dissipated. It is essentially the deutoxide (peroxide) of mercury, consisting of one equivalent of the metal 200, and two of oxygen 16 = 216, or, according to the Br. Pharmacopœia, the protoxide, consisting of one eq. of mercury 100, and one of oxygen 8 = 108; but, in its ordinary state, it always contains a minute proportion of nitric acid, probably in the state of subnitrate. According to Brande, when rubbed and washed with a solution of potassa, edulcorated with distilled water, and carefully dried, it may be regarded as nearly pure deutoxide. It is said to be sometimes adulterated with brickdust, red lead, &c.; but these may be readily detected, as the oxide of mercury is wholly dissipated if thrown upon red-hot iron. The disengagement of red vapours, when it is heated, indicates the presence of nitrate of mercury. The same or some other saline impurity would be indicated, should water, in which the oxide has been boiled, afford a precipitate with lime-water.

Medical Properties and Uses. This preparation is too harsh and irregular in its operation for internal use; but is much employed externally as a stimulant and escharotic, either in the state of powder or of ointment. In the former state it is sprinkled on the surface of chancres, and indolent, flabby, or fungous ulcers; and, mixed with 8 or 10 parts of finely powdered sugar, is sometimes blown into the eye to remove opacity of the cornea. The powder should be finely levigated. The ointment is officinal.*

Off. Prep. Hydrargyri Cyanidum, *U. S.;* Unguentum Hydrargyri Oxidi Rubri. W.

* *Black Oxide of Mercury. Oxidum Hydrargyri Nigrum.* U. S. 1850. Though discarded from the Pharmacopœia, this preparation still has claims to notice. It was obtained by the following officinal process.

"Take of Mild Chloride of Mercury [calomel], Potassa, each, *four ounces;* Water *a pint.* Dissolve the Potassa in the Water, and, when the dregs have subsided, pour off the clear solution. To this add the Mild Chloride of Mercury, and stir them constantly together till the Black Oxide is formed. Having poured off the supernatant liquor, wash the Black Oxide with distilled water, and dry it with a gentle heat." *U. S.* 1850.

The object of this process is to obtain the protoxide or black oxide of mercury, which was at one time believed to be the active constituent of those preparations in which the metal is minutely divided by trituration. The calomel is completely decomposed by the solution of potassa; its chlorine uniting with potassium to form chloride of potassium, which remains in solution, and the mercury with the oxygen of the potassa to form protoxide of mercury, which subsides. More potassa is employed than by calculation would seem to be requisite; but it has been ascertained by experiment that a considerable excess is necessary for the complete decomposition of the calomel. The use of the officinal solution of potassa is preferable, on the score of economy, to that of a solution extemporaneously prepared from the caustic alkali. In order to ensure the success of the process, the calomel, very finely levigated, should be rubbed quickly with the alkaline solution in a mortar; and the resulting oxide should be dried in the dark with a very gentle heat, as it is decomposed by the agency both of light and of an elevated temperature. For the same reason it should be preserved in an opaque bottle. This mode of preparing the black oxide of mercury originated with Mr. Donovan.

HYDRARGYRI SULPHAS. *Sulphate of Mercury. Br. Appendix.*

"Take of Mercury, by weight, *twenty ounces* [avoirdupois]; Sulphuric Acid *twelve fluidounces* [Imperial measure]. Heat the Mercury with the Sulphuric Acid in a porcelain vessel until the metal disappears, then continue the heat until a dry white salt remains." *Br. Appendix.*

Mercury is not acted on by cold sulphuric acid; but, when boiled with an excess of this acid to dryness, it is deutoxidized at the expense of part of the acid, sulphurous acid being copiously evolved; and the deutoxide formed unites with the undecomposed portion of the sulphuric acid, so as to form bisulphate of deutoxide of mercury, which is the officinal sulphate.

Sulphate of mercury, as obtained by a separate formula, is peculiar to the British Pharmacopœia; but it is formed as the first step of the processes of the U. S. Pharmacopœia for preparing corrosive sublimate, calomel, and turpeth mineral. The adoption of a separate formula and distinct officinal name for this salt is certainly a convenience; as it obviates the necessity of repeating the directions for obtaining the same substance in several formulas. On account of its various uses, it requires to be made on a large scale by the manufacturing chemist; and the process is generally performed in a cast-iron vessel, which

The oxide may also be prepared by decomposing a solution of nitrate of protoxide of mercury by solution of potassa. This nitrate may be obtained by treating 20 parts of mercury with 18 parts of nitric acid of 25° Baumé, adding, when nitrous vapours cease to rise, 10 parts of warm distilled water, boiling for a short time, decanting the clear liquor, and setting it aside to crystallize. The mother-waters by evaporation will furnish a new product of crystals of nitrate of protoxide. (Ratier, *Pharm. Franç.*) The London College formerly prepared this oxide by decomposing calomel with lime-water; but it is extremely difficult to effect a complete decomposition in this way, and the preparation was consequently almost always mixed with calomel. The preparation, officinal in a former Dublin Pharmacopœia under the name of *Pulvis Hydrargyri Cinereus*, made by adding carbonate of ammonia to a solution of mercury in heated nitric acid, was a mixture of subnitrate of mercury and ammonia with protoxide of mercury. Both the London and Dublin Colleges abandoned the protoxide in the latest editions of their Pharmacopœias.

Properties, &c. As first prepared, this oxide is greenish-black; but, as found in the shops, it is almost always of an olive colour. It is inodorous, tasteless, and said to be insoluble in water and alkaline solutions; but, according to Mr. Charles Bullock, it is appreciably soluble in cold water, and to a greater extent in boiling water, but is insoluble in cold alcohol and ether. (*Proceedings of the Am. Pharm. Assoc.*, 1858, p. 302). It consists of one eq. of mercury 200, and one of oxygen 8=208. On exposure to light or heat it is decomposed, one part assuming the metallic state, in consequence of the loss of its oxygen, which converts another part into the deutoxide. The preparation, therefore, becomes a mixture of the protoxide, deutoxide, and metallic mercury, with which calomel is sometimes associated, in consequence of the incomplete decomposition of that employed in the process. By a strong heat it is completely dissipated, and metallic globules are sublimed. When pure it is soluble in acetic and nitric acids, and entirely insoluble in muriatic acid, which forms with it water and calomel. If it contain the deutoxide, this will be dissolved by muriatic acid, and may be detected in the solution by the production of a white precipitate with water of ammonia, and a yellow one with solution of potassa. Calomel, if present, may be discovered by boiling the powder with a solution of potassa, thus forming chloride of potassium, which, when the solution is saturated with nitric acid, will afford a white precipitate of chloride of silver on the addition of nitrate of silver. (*Phillips.*)

Medical Properties and Uses. The black oxide is alterative, sialagogue, and purgative. It may be employed for the same purposes as calomel, over which, however, it has not in our hands exhibited any superiority, while, from the occasional presence of the deutoxide, it must be liable to operate harshly. Dr. B. H. Coates, of this city, informed us some years since that he used it habitually as a mercurial, and found it to answer an excellent purpose. The idea under which it was introduced into use, that it was the basis of the blue pill, is erroneous. Made into an ointment with lard, according to the process of Donovan, it may be applied externally with good effect in bringing the system under the mercurial influence. (See *Unguentum Hydrargyri.*) Its dose as an alterative is one-fourth or half of a grain daily, as a sialagogue from one to three grains two or three times a day, given in the form of pill. It was used by Mr. Abernethy for mercurial fumigation; the patient being placed, covered with under garments, in a vapour-bath, and exposed for 15 or 20 minutes to the vapours arising from two drachms of the oxide, put upon heated iron within the bath. W.

should be conveniently arranged for the escape and decomposition of the sulphurous acid fumes, which otherwise become a serious nuisance to the neighbourhood. The best way to effect this purpose is to allow them to pass off through a very lofty chimney, mixed with abundance of coal smoke.

Properties, &c. Sulphate of mercury is in the form of a white saline mass. It consists of two eqs. of acid 80 and one of deutoxide of mercury 216 = 296; or, according to the Br. Pharmacopœia, of one eq. of acid 40 and one of protoxide of mercury 108 = 148. It has no medical uses.

HYDRARGYRI SULPHAS FLAVA. *U.S. Yellow Sulphate of Mercury. Turpeth Mineral.*

"Take of Mercury *four troyounces;* Sulphuric Acid *six troyounces.* Mix them in a glass vessel, and boil, by means of a sand-bath, until a dry white mass remains. Rub this into powder, and throw it into boiling water. Pour off the supernatant liquor, wash the yellow precipitate repeatedly with hot water, and dry it." *U. S.*

By referring to the articles on corrosive sublimate and calomel, it will be found that the peculiar salt which is generated by boiling sulphuric acid with mercury to dryness, is directed to be made as the first step for obtaining these chlorides; and here the same salt is again directed to be formed in preparing turpeth mineral. We have already stated that this salt is the bisulphate of deutoxide of mercury. When thrown into boiling or even warm water it is instantly decomposed, and an insoluble salt is precipitated, which is the turpeth mineral. According to Berzelius, turpeth mineral is a basic sesquisulphate of deutoxide of mercury, and the supernatant solution contains a supersulphate, consisting of six eqs. of acid and one of base. The same composition for turpeth mineral is given by Gay-Lussac; and its accuracy was verified by Sir Robert Kane, of Dublin. (See *Pharm. Journ.*, August, 1842.) The composition above given of turpeth mineral implies the decomposition of four eqs. of bisulphate of deutoxide, and the manner in which the reaction takes place is shown by the following equation; $4(HgO_2.2SO_3) =$ turpeth mineral, $3HgO_2,2SO_3$, and supersulphate of mercury, $HgO_2,6SO_3$.

Properties, &c. Yellow sulphate of mercury is a lemon-yellow powder, of a somewhat acrid taste. It dissolves in 2000 parts of cold, and about 600 of boiling water. Exposed to a moderate heat, it becomes first red and afterwards brownish-red, but regains its original colour on cooling. (*Barker.*) At a red heat it is decomposed and dissipated, sulphurous acid being evolved, and metallic globules sublimed. It was originally called *turpeth* mineral, from its resemblance in colour to the root of *Ipomæa Turpethum.*

Medical Properties and Uses. Turpeth mineral is alterative, and powerfully emetic and errhine. As an alterative, it has been given in leprous disorders and glandular obstructions. It has been usefully employed as an emetic, repeated every few days, in chronic enlargement of the testicle. It operates with great promptness, and sometimes excites ptyalism. Dr. Hubbard, of Maine, considers it a valuable emetic, in cases requiring an equalizing and revulsive effect, apart from any cathartic operation, which he has never known it to produce. He recommends it highly as an emetic in croup, on the ground of its promptness and certainty, and of its not producing catharsis, or the prostration caused by antimony. The dose for a child two years old is two or three grains, repeated in fifteen minutes, if it should not operate. As an errhine, it has been used with benefit in chronic ophthalmia; but it sometimes produces salivation when thus employed. The dose as an alterative is from a quarter to half a grain; as an emetic from two to five grains. When employed as an errhine, one grain may be mixed with five of starch or powdered liquorice root.

Turpeth mineral, in an overdose, acts as a poison. A case of death in a boy

aged sixteen, caused by swallowing a drachm, is reported by Dr. Letheby in the *London Medical Gazette* for March, 1847. B.

HYDRARGYRI SULPHURETUM RUBRUM. *U. S.* CINNABARIS. *Ed. Red Sulphuret of Mercury. Bisulphuret of Mercury. Cinnabar.*

"Take of Mercury *forty troyounces;* Sulphur *eight troyounces.* To the Sulphur, previously melted, gradually add the Mercury, with constant stirring, and continue the heat until the mass begins to swell. Then remove the vessel from the fire, and cover it closely to prevent the contents from inflaming. When the mass is cold, rub it into powder, and sublime." *U. S.*

This preparation has been discarded, we think somewhat prematurely, by the British Council.

Mercury and sulphur, when heated together, unite with great energy, and a product is obtained, which by sublimation becomes the red or bisulphuret of mercury. In order to render the combination more prompt, the sulphur is first melted; and the addition of the mercury should be made gradually, while the mixture is constantly stirred. Dr. Barker recommends the addition of the metal by straining it upon the melted sulphur through a linen cloth, whereby it falls in a minutely divided state. When the temperature has arrived at a certain point, the combination takes place suddenly with a slight explosion, attended with the inflammation of the sulphur, which must be extinguished by covering the vessel. A black mass will thus be formed, containing generally an excess of sulphur, which, before the sublimation is performed, should be got rid of by gently heating the matter, reduced to powder, on a sand-bath. The sublimation is best performed, on a small scale, in a loosely stopped glass matrass, which should be placed in a crucible containing sand, and, thus arranged, exposed to a red heat. The equivalent quantities for forming this sulphuret are 32 of sulphur and 200 of mercury.

Preparation on the Large Scale. Cinnabar is seldom prepared on a small scale, being made in large quantities for the purposes of the arts. In Holland, where it is principally manufactured, the sulphur is melted in a cast-iron vessel, and the mercury is added in a divided state, by causing it to pass through chamois leather. As soon as the combination has taken place, the iron vessel is surmounted by another, into which the cinnabar is sublimed. The larger the quantity of the materials employed in one operation, the finer will be the tint of the product. It is also important in the manufacture to use the materials pure, and to drive off any uncombined sulphur which may exist in the mass, before submitting it to sublimation.

Properties, &c. Red sulphuret of mercury is in the form of heavy, brilliant, crystalline masses, of a deep-red colour and fibrous texture. It is inodorous and tasteless, and insoluble in water and alcohol. It is not acted on by nitric, muriatic, or cold sulphuric acid, or by solutions of the caustic alkalies; but is soluble in nitromuriatic acid, on account of the free chlorine which the mixed acid contains. When heated with potassa, it yields globules of mercury. In the open air it is decomposed by heat, the sulphur becoming sulphurous acid, and the mercury being volatilized. In close vessels at a red heat it sublimes without decomposition, and condenses in a mass, composed of a multitude of small needles. When duly levigated, it furnishes a brilliant red powder, which is the paint called *vermilion.* The same compound occurs native, being the sole ore from which mercury is extracted. The preparation, if purchased in powder, should be carefully examined; as, in that state, it is sometimes adulterated with red lead, dragon's blood, or chalk. If red lead be present, acetic acid, digested with it, will yield a yellow precipitate (iodide of lead) with iodide of potassium. Dragon's blood may be detected by alcohol, which will take up the colouring matter of that substance, if present; and, if chalk be mixed with it, effervescence

will be excited on the addition of an acid. This sulphuret consists of one eq. of mercury 200, and two of sulphur 32=232.

Medical Properties and Uses. Cinnabar was formerly thought to be alterative and anthelmintic, but is at present seldom given internally. It is sometimes employed by fumigation, as a rapid sialagogue, in venereal ulcers of the nose and throat, in cases in which it is important to bring the system under the influence of mercury in the shortest possible time. The dose internally is from ten grains to half a drachm, in the form of electuary or bolus. When used by fumigation, half a drachm may be thrown on a red-hot iron, and the fumes inhaled as they arise. These consist of sulphurous acid gas and mercurial vapour, the former of which must prove highly irritating to the patient's lungs. A better substance for mercurial fumigation is the black oxide of mercury.* B.

HYDRARGYRUM AMMONIATUM. *U. S.*, *Br.* HYDRARGYRI PRECIPITATUM ALBUM. *Ammoniated Mercury. White Precipitate.*

"Take of Corrosive Chloride of Mercury *six troyounces;* Water of Ammonia *eight fluidounces;* Distilled Water *eight pints.* Dissolve the Corrosive Chloride of Mercury in the Distilled Water, with the aid of heat, and to the solution, when cold, add the Water of Ammonia, frequently stirring. Wash the precipitate with water until the washings become nearly tasteless, and dry it." *U. S.*

"Take of Corrosive Sublimate *three ounces* [avoirdupois]; Solution of Am-

* *Black Sulphuret of Mercury. Ethiops Mineral. Hydrargyri Sulphuretum Nigrum.* Though very properly discarded from the Pharmacopœias, this has too long occupied a place in the catalogue of the Materia Medica to be passed over entirely without notice. The following was the formula of the U. S. Pharmacopœia of 1850, for its preparation.

"Take of Mercury, Sulphur, each, *a pound.* Rub them together till all the globules disappear." *U. S.*

Mercury and sulphur have a strong affinity for each other, as is shown by the fact, that, when they are triturated together in quantities, the mixture grows hot, cakes, and exhales a sulphurous odour. During the trituration, the mixture should be sprinkled from time to time with a little water or alcohol, to prevent the dust from rising, which exposes the operator to serious inconvenience. When rubbed together in equal weights, as directed in the formula, they are supposed to unite chemically: but the proportion of sulphur is much greater than is necessary to form a definite compound. Only two sulphurets of mercury have been admitted by chemists generally, the protosulphuret, and bisulphuret or cinnabar; but the quantity of sulphur directed in the process is much more than sufficient to form even the latter. It is still undetermined what is the exact nature of the officinal black sulphuret, or *ethiops mineral.* Mr. Brande, from his experiments, considers it to be the bisulphuret mixed with sulphur. Thus, he found that, when boiled repeatedly in solution of potassa, sulphur was dissolved, and a black insoluble powder was left, which sublimed without decomposition, and yielded a substance having all the characters of cinnabar.

Ethiops mineral is sometimes obtained by melting sulphur in a crucible, and adding to it an equal weight of mercury; but, when thus prepared, the sulphur is apt to become acidified, and the preparation to acquire an activity which does not belong to it when obtained by trituration.

Properties, &c. Black sulphuret of mercury is a heavy, tasteless, insoluble powder. When exposed to heat, it becomes of a dark-violet colour, emits the excess of sulphur in sulphurous acid fumes, and sublimes in brilliant red needles without residue. If charcoal be present it will remain behind. When well prepared, no globules of mercury are discernible in it when viewed with a magnifier; and, if rubbed on a gold ring, it should not communicate a white stain. Ivory black is detected in it by throwing a small portion on red-hot iron, when a white matter (phosphate of lime) will be left behind. Adulteration by sulphuret of antimony is shown, if muriatic acid, boiled on a portion of the powder, acquires the property of causing a precipitate of oxychloride of antimony when added to water. According to the views of Mr. Brande, ethiops mineral consists of one eq. of bisulphuret of mercury, mixed with about ten and a half eqs. of sulphur in excess.

Medical Properties. Ethiops mineral is supposed to be alterative, and as such has been sometimes prescribed in glandular affections and cutaneous diseases, especially in the cases of scrofulous children, to which, from the mildness of its operation, it has been thought to be well adapted. The dose generally given was from five to thirty grains, repeated several times a day; but it has often been administered in much larger doses, without producing any obvious impression on the system. At present it is very little used as a medicine. B.

monia *four ounces* [avoird.]; Distilled Water *three pints* [Imperial measure]. Dissolve the Corrosive Sublimate in the Water with the aid of a moderate heat; mix the Solution with the Ammonia, constantly stirring; collect the precipitate on a filter, and wash it well with cold Distilled Water until the liquid which passes through ceases to give a precipitate when dropped into a solution of nitrate of silver acidulated with nitric acid. Lastly, dry the product at a temperature not exceeding 212°." *Br.*

The Pharmacopœias now agree in obtaining white precipitate by precipitating a solution of corrosive sublimate by ammonia. When ammonia, in slight excess, is added to a cold solution of corrosive sublimate, muriate of ammonia is formed in solution, and the white precipitate of the Pharmacopœias is thrown down. The precipitate is washed, according to the U. S. formula, until the washings become nearly tasteless, according to the British, with greater precision, until they cease to give evidence of the presence of a chloride by producing a precipitate with nitrate of silver acidulated with nitric acid. The matter washed away is muriate of ammonia and the excess of ammonia employed; and hence the washings, agreeably to the directions of the British formula, are tested with an acid solution of nitrate of silver. According to Sir Robert Kane, white precipitate has a composition corresponding to one eq. of bichloride of mercury, united with one eq. of a compound consisting of one eq. of mercury combined with two eqs. of a hypothetical body represented by one eq. of ammonia *minus* one eq. of hydrogen. This hypothetical body, represented by NH_2, he has named *amidogen*, the *amide* of some chemists. The reaction may be supposed to take place between four eqs. of ammonia and two of bichloride of mercury. Two eqs. of ammonia by parting with one eq., each, of hydrogen, become two eqs. of amidogen, which unite with the mercury of one eq. of the bichloride to form the binamide of mercury; while the two liberated eqs. of hydrogen of the ammonia combine with the two liberated eqs. of chlorine of the bichloride, forming two eqs. of muriatic acid; and the binamide then unites with the second eq. of the bichloride to produce the insoluble chloro-amide of mercury or white precipitate, which falls. The two eqs. of muriatic acid combine with a like number of ammonia, and remain in solution as two eqs. of muriate of ammonia. In symbols the reaction is thus denoted: $4NH_3$ and $2HgCl_2 = Hg,2NH_2 + HgCl_2$ and $2(NH_3,HCl)$. For an account of ammonium, see *page* 95. The analysis of Kane agrees virtually with those of Guibourt and Hennell.

Properties, &c. Ammoniated mercury is in powder or pulverulent masses, perfectly white, insoluble in water and alcohol, decomposed by boiling water, and having a taste at first earthy, and afterwards metallic. It dissolves without effervescence in muriatic acid. When heated with a solution of caustic potassa, it yields ammonia and becomes yellow. Exposed to a strong heat it is entirely dissipated, and resolved into nitrogen, ammonia, and protochloride of mercury. Adulteration with white lead, chalk, or sulphate of lime may be detected by exposing a sample to a strong red heat, when these impurities will remain. Should starch be mixed with it, a charry residue will be obtained on the application of heat. Lead or starch may be found by digesting it with acetic acid, and testing the acetic solution with the compound solution of iodine, which will give a yellow precipitate if lead, and a blue one if starch be present. The absence of protoxide of mercury is shown by its not being blackened when rubbed with lime-water. Ammoniated mercury is used only as an external application.

Ammoniated mercury has been swallowed by mistake. It is highly poisonous, producing gastric pain, nausea, and purging. A case of recovery, after taking what was estimated to be half a drachm, is reported in the London *Lancet* for July 4, 1857. The remedies employed were an emetic of sulphate of zinc, and milk to allay the gastro-intestinal irritation.

Off. Prep. Unguentum Hydrargyri Ammoniati. B.

HYDRARGYRUM CUM CRETA. *U. S.*, *Br.* *Mercury with Chalk. Gray Powder.*

"Take of Mercury *three troyounces;* Prepared Chalk *five troyounces.* Rub them together until the globules cease to be visible, and the mixture acquires a uniform gray colour." *U. S.*

"Take of Mercury, by weight, *one ounce;* Prepared Chalk *two ounces.* Rub the Mercury and Chalk in a porcelain mortar until metallic globules cease to be visible to the naked eye, and the mixture acquires a uniform gray colour." *Br.*

When mercury is triturated with certain dry and pulverulent substances, such as chalk or magnesia, it gradually loses its fluidity and metallic lustre, and becomes a blackish or dark-gray powder. A similar change takes place when it is rubbed with viscid or greasy substances, such as honey or lard. The globules disappear, so as in some instances not to be visible even through a good lens; and the mercury is said to be extinguished. It was formerly thought that the metal was oxidized in the process. At present, the change is generally ascribed to the mechanical division of the metal, which in this state is supposed to be capable of acting on the system. There is good reason, however, to believe that in this, as in all the analogous preparations of mercury, in which the metal is extinguished by trituration, a very small portion is converted into protoxide, while by far the greater part remains in the metallic state.

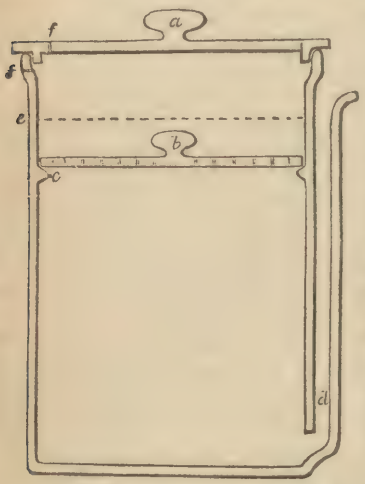
Mercury with chalk is a grayish powder, in which globules of mercury can generally be seen with the aid of a microscope; as the metal can scarcely be completely extinguished with chalk alone by any length of trituration. Mr. Jacob Bell found that, by powerfully pressing it, a considerable quantity of metal was separated in the form of globules. Mr. Phillips states that the extinguishment of the mercury is greatly accelerated by the addition of a little water. Dr. Stewart, of Baltimore, proposed the following process, by which he stated that the preparation might be completed in a short time, so that no globules should be visible with a powerful lens. Three ounces of mercury and six ounces of resin are to be rubbed together for three hours; five ounces of chalk are to be added, and the trituration continued for an hour; the mixture is then to be heated with alcohol so as to dissolve the resin; and the remaining powder is to be dried on bibulous paper, and well rubbed in a mortar. (*Am. Journ. of Pharm.*, xv. 162.) But Professor Procter has shown that the preparation thus made contains deutoxide of mercury, and is, therefore, injuriously harsh in its operation. (*Ibid.*, xxii. 113.) It is said that the precipitated black oxide is sometimes added with a view to save time in the trituration; but this must be considered as an adulteration, until it can be shown that the same oxide exists, in the same proportion, in the preparation made according to the officinal directions. Dr. Ed. Jenner Coxe, of New Orleans, has found that the extinguishment of the mercury may be effected much more speedily than in the ordinary manner, by putting the ingredients into a quart bottle, to be well corked, and kept in constant agitation till the object is attained. A portion of the chalk may be thus shaken with the metal until no globules can be seen, and the process completed by trituration with the remainder of the chalk in a mortar. This mode of proceeding was suggested to Dr. Coxe by Mr. W. Hewson, of Augusta, Ga. (*Ibid.*, xxii. 317.) Dr. Squibb, having ascertained that the preparation cannot be satisfactorily made in this way on a large scale (*Proceed. of Am. Pharm. Assoc.*, 1858, p. 424), has invented a machine for accomplishing the same object, by which the requisite motion is imparted to the materials contained in two large bottles, and which is said to answer the purpose well. By means of this apparatus, Dr. Squibb prepares mercury with chalk on a large scale, mixing the materials in the officinal proportions, but aiding the extinguishment of the metal by adding to it about one-seventh of its weight of honey, and making the chalk into a paste with water before introducing it into the bottles. (*Ibid.*, 1859, p. 359.) As found in

commerce, mercury with chalk, instead of being the mild preparation it was intended to be, sometimes acts very harshly, producing vomiting, gastric pains, &c. This has been ascribed to the presence of antimony or arsenic, existing as impurities in the mercury employed; but this can seldom happen; and the ordinary cause of the harshness is no doubt peroxide of mercury, produced in minute proportion either by improper modes of preparation, or by too long a perseverance in trituration, or by the spontaneous change which occurs with time; the protoxide being converted into deutoxide by the influence of light. The only method to guard against such results is to make the preparation strictly according to the officinal process, or carefully to test before dispensing it. If the mercury contained in the preparation be volatilized by heat, and the remaining chalk be dissolved by dilute acetic acid, the solution should not be coloured by sulphuretted hydrogen. The presence of any probable metallic impurity may be detected in this way. To detect peroxide of mercury, a portion of the powder may be treated with dilute muriatic acid with a moderate heat, and the solution tested by protochloride of tin, which if there be any peroxide in the preparation, will cause a precipitation of metallic mercury in the form of a black powder.

Medical Properties and Uses. Mercury with chalk is a very mild mercurial, similar in its properties to the blue pill, but much weaker. It is sometimes used as an alterative, particularly in the complaints of children attended with deficient biliary secretion, indicated by white or clay-coloured stools. The chalk is antacid, and, though in small quantity, may sometimes be a useful accompaniment of the mercury in diarrhœa. Eight grains of the U. S. preparation contain three grains of mercury. The dose is from five grains to half a drachm twice a day. Two or three grains is the dose for a child. It should not be given in pill with substances which become hard on keeping; as the contraction of the mass presses together the particles of mercury, which, in time, appear in globules in the interior of the pill. W.

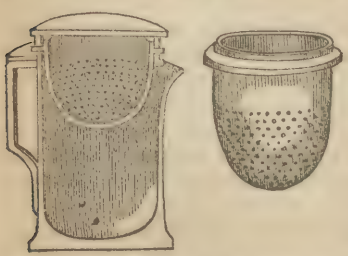
INFUSA.

Infusions.



These are aqueous solutions obtained by treating with water, without the aid of ebullition, vegetable products only partially soluble in that liquid. The water employed may be hot or cold, according to the objects to be accomplished. Infusions are generally prepared by pouring boiling water upon the vegetable substance, and macerating in a lightly closed vessel till the liquid cools. The soluble principles are thus extracted more rapidly, and, as a general rule, in a larger proportion than at a lower temperature. Some substances, moreover, are dissolved in this manner, which are nearly or quite insoluble in cold water. A prolonged application of heat is in some instances desirable; and this may be effected by placing the vessel near the fire. Cold water is preferred when the active principle is highly volatile, when it is injured by heat, or when any substance of difficult solubility at a low temperature exists in the vegetable, which it is desirable to avoid in the infusion. A longer continuance of the maceration is necessary in this case; and, in warm weather, there is sometimes danger that spontaneous decomposition may commence before the process is completed. When a strong infusion is required, the *process of percolation* may be advantageously resorted to. (See *pages* 894 and 905.) The water employed should be free from saline impurities, which frequently produce precipitates, and render the infusion turbid. Fresh river, rain, or distilled water is usually preferable to that of pumps or springs.

The substance to be acted on should be sliced or bruised, or in the state of powder; but, unless when percolation is employed, this last condition is seldom requisite, and is always inconvenient, as it requires that the infusion should be



filtered through paper in order completely to separate the undissolved portion. In other cases, it is sufficient to strain through fine linen or muslin. When percolation is resorted to, the substance should be more or less finely powdered. Infusions are usually prepared in glazed earthenware or porcelain vessels fitted with covers. Mr. Braude suggests the use of clean metallic vessels, which, when finely polished, retain the heat for a longer time; but they are also more liable to chemical alteration, and may sometimes injuriously affect the preparation. Vessels of block-tin are generally well adapted for the purpose.*

As infusions do not keep well, especially in warm weather, they should be made extemporaneously and in small quantities. In this country they are usually prepared in families, and the propriety of their introduction into the Pharmacopœia has been doubted; but it is desirable to have certain fixed standards for the regulation of the medical practitioner; and it is sometimes convenient to direct infusions from the apothecary, for whose guidance officinal formulas are necessary. Physicians would, indeed, find their advantage in more frequently directing

* *Alsop's Infusion Jar.* This presents a very neat and effectual method of making the hot infusions. It consists of an earthenware mug, represented in the marginal figure, with a spout (*d*) proceeding from the bottom, and placed closely to the side of the vessel to prevent fracture; a perforated plate or diaphragm (*b*), supported on a ledge (*c*), at about one-quarter or one-third of the height of the vessel from the top; and a lid (*a*), which may be fastened on by a string through holes (*ff*). The material to be submitted to infusion is placed on the perforated plate, and the hot water poured in so as to cover it, the vessel having been previously warmed so as not to chill the liquid. As the water becomes impregnated, it acquires an increased specific gravity, and sinks to the bottom, its place being supplied by the unsaturated portion; and this circulation goes on until the whole of the soluble matter is extracted. In order to maintain a due warmth, the vessel may be placed upon a stove or an iron plate near the fire. The advantage of the process is that the material is subjected to the solvent power of the least impregnated portion of the menstruum. Such jars may now be had in Philadelphia. In order that the vessel may be adapted for the preparation of different quantities of infusions, it will be proper to have ledges arranged within at different heights, so that the diaphragm may be supported at any desirable point. The surface of the liquid (*e*) should of course always be above the medicinal substance placed upon the diaphragm. (See *Am. Journ. of Pharm.*, viii. 89.)

Squire's Infusion Jar. Mr. Squire, of London, has modified this jar by adding a colander of queensware, which is closely covered with a lid, and descends into the jar so as to form a diaphragm for the support of the substance to be infused. It has the advantage that the material, after having been exhausted, may be lifted out without disturbing the infusion. In the margin is a figure of Squire's implement. It consists of a queensware mug, of the capacity of two pints, into which a thimble-shaped colander descends to somewhat less than half its depth, supported on the rim of the mug by a projecting ledge, with a carefully fitted cover, which closes the whole. The substance to be submitted to infusion is introduced into the colander either before or after it has been fitted to the mug; the water, hot or cold, as the case may be, is then poured in so as to fill the lower vessel, and cover the materials in the upper; and, the cover having been applied, the vessel is set aside for the length of time required. The colander is then to be lifted out, and the infusion is ready for use. For preparing small quantities of infusion, a pint for example, the mug must be made of a smaller size.

them from the shops, instead of leaving their preparation to the carelessness or want of skill of attendants upon the sick. For a mode of preserving infusions, the reader is referred to the introductory observations, *page* 899. By making very concentrated infusions, as suggested by Mr. Donovan, with a mixture of three parts of water and one of alcohol, they may be long kept, and when used can be diluted with water to the proper strength. Thus, if made four times as strong as the officinal infusion, they may be diluted with three measures of water. The proportion of alcohol would thus be very small; but it might still be medically injurious; and infusions should not be prepared in this way unless with the cognizance of the prescriber.

Mr. Battley, of London, has introduced a new set of preparations, which he calls *inspissated infusions*, the advantages of which are that the virtues are extracted by cold water, are not injured by heat used in the evaporation, are in a concentrated state, and are not impaired by time. To prepare them he macerates the material, coarsely powdered, bruised, or finely sliced, in twice its weight of cold distilled water, pressing the solid matter into the liquid repeatedly by a rammer or the hand; then allows the liquid to drain out, or expresses it in the case of highly absorbent substances; and repeats the process, with an amount of water equal to that which has been separated, until the strength is exhausted. Four or six hours of maceration are usually sufficient. The infusion is then to be concentrated by evaporation at a temperature not exceeding 160° to the sp. gr. 1·200, and as much alcohol is to be added as will make its sp. gr. 1·100. These preparations are very analogous to the *fluid extracts* already treated of. As a general rule it would probably be preferable to prepare the infusion by the process of percolation. The inspissated infusions must be diluted when administered. The presence of alcohol, though in small quantity, would in some instances be a serious objection. (*Pharm. Journ.*, x. 129.)

As we have already treated of the chemical relations and medical properties of the substances used in infusion, it would be useless repetition to enlarge upon these points in the following details. We shall touch upon them only in cases of peculiar interest, or where changes requiring particular notice may grow out of the nature of the process.

The former officinal preparations of this class, omitted in the present U. S. and Br. Pharmacopœias, are the *Infusions of Horseradish*, U. S., Lond., of *Pale Peruvian Bark*, Lond., Dub., Ed., and of *Simaruba*, Ed., Dub.; the *Inspissated Infusions of Yellow and Pale Bark*, Lond.; and the *Compound Infusion of Senna*, Ed. The U. S. *Infusions of Sassafras Pith* and of *Slippery-elm Bark* have been transferred to the *Mucilages*. W.

INFUSUM ANGUSTURÆ. *U. S.* Infusum Cusparіæ. *Br. Infusion of Angustura. Infusion of Cusparia.*

"Take of Angustura [Bark], in moderately coarse powder, *half a troyounce;* Water *a sufficient quantity.* Moisten the powder with two fluidrachms of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the filtered liquid measures a pint.

"This Infusion may also be prepared by macerating the Angustura in a pint of Boiling Water, for two hours, in a covered vessel, and straining." *U. S.*

"Take of Cusparia, in coarse powder, *half an ounce* [avoirdupois]; Distilled Water, at 120°, *ten fluidounces.* Infuse in a covered vessel, for two hours, and strain." *Br.*

The dose of the infusion is two fluidounces, repeated every two, three, or four hours. W

INFUSUM ANTHEMIDIS. *U. S., Br. Infusion of Chamomile.*

"Take of Chamomile *half a troyounce;* Boiling Water *a pint.* Macerate for ten minutes in a covered vessel, and strain." *U. S.*

"Take of Chamomile Flowers *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for fifteen minutes, and strain." *Br.*

The infusion of chamomile has the odour and taste of the flowers. It affords precipitates with gelatin, yellow Peruvian bark, sulphate of iron, tincture of chloride of iron, nitrate of silver, corrosive chloride of mercury, and the acetates of lead. (*London Dispensatory.*) As a tonic it is given cold, in the dose of two fluidounces several times a day. To assist the operation of emetic medicines it should be administered in the tepid state, and in large draughts. The infusion prepared by maceration in cold water is more grateful to the palate and stomach than that made with boiling water, but is less efficient as an emetic. W.

INFUSUM AURANTII. *Br. Infusion of Orange Peel.*

"Take of Bitter Orange Peel, cut small, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for fifteen minutes, and strain." *Br.*

This infusion is given as a grateful stomachic, in the dose of two or three fluidounces. W.

INFUSUM BUCHU. *U. S.* Infusum Bucco. *Br. Infusion of Buchu.*

"Take of Buchu *a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Buchu, bruised, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

This is the *Infusum Diosmæ* of former Pharmacopœias. It has the odour, taste, and medical virtues of the leaves, and affords a convenient method of administering the medicine. The dose is one or two fluidounces. W.

INFUSUM CALUMBÆ. *U. S., Br.* Infusum Colombæ. *U. S.* 1850. *Infusion of Columbo. Infusion of Calumbo.*

"Take of Columbo, in moderately coarse powder, *half a troyounce;* Water *a sufficient quantity.* Moisten the powder with two fluidrachms of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the filtered liquid measures a pint.

"This Infusion may also be prepared by macerating the Columbo in a pint of boiling Water, for two hours, in a covered vessel, and straining." *U. S.*

"Take of Calumbo, in coarse powder, *half an ounce* [avoirdupois]; Cold Distilled Water *ten fluidounces.* Macerate for one hour, and strain." *Br.*

The infusion of columbo is apt to spoil very quickly, especially in warm weather. It has been generally supposed that the cold infusion would keep better than the hot, because it contains no starch. Mr. Thomas Greenish, however, upon comparing specimens of the two infusions, found that the spontaneous change began sooner in the cold than the hot, though the former was clearer. Columbo contains starch and albumen. Cold water extracts the latter without the former; hot water the former with comparatively little of the latter, which is partially coagulated by the heat. Both starch and albumen are liable to spontaneous change; but the former is much the more permanent of the two. Hence it is, according to Mr. Greenish, that the hot infusion keeps best. Indeed, he ascribes the change which takes place in the starch of the hot infusion chiefly to the agency of a little albumen, which has escaped coagulation. According to these views, the best plan of preparing infusion of columbo is to exhaust the root with cold water, by which the starch is left behind, and then to heat the infusion to the boiling point in order to coagulate the albumen. (*Am. Journ. of Pharm.*, xviii. 141, from *Pharm. Journ.*) Upon comparing specimens of the cold and hot infusion, we have not found the results of Mr. Greenish fully confirmed. The cold infusion appeared to keep better than the hot. Nevertheless, the plan of preparing the infusion above proposed is probably the best. The

infusion of columbo is not disturbed by salts of iron, and may be conveniently administered in connection with them. The dose is two fluidounces three or four times a day. W.

INFUSUM CAPSICI. *U. S. Infusion of Capsicum.*

"Take of Capsicum, in coarse powder, *half a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

This infusion is used chiefly as a gargle. It may, however, be given internally in the dose of half a fluidounce. W.

INFUSUM CARYOPHYLLI. *U. S., Br. Infusion of Cloves.*

"Take of Cloves, bruised, *one hundred and twenty grains;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Cloves, bruised, *a quarter of an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for half an hour, and strain." *Br.*

The infusion of cloves affords precipitates with lime-water, and with the soluble salts of iron, zinc, lead, silver, and antimony. (*Phillips.*) The dose is about two fluidounces. W.

INFUSUM CASCARILLÆ. *U. S., Br. Infusion of Cascarilla.*

"Take of Cascarilla, in moderately coarse powder, *a troyounce;* Water *a sufficient quantity.* Moisten the powder with half a fluidounce of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the filtered liquid measures a pint.

"This Infusion may also be prepared by macerating the Cascarilla with a pint of boiling Water, for two hours, in a covered vessel, and straining." *U. S.*

"Take of Cascarilla, in coarse powder, *one ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

This infusion affords precipitates with lime-water, infusion of galls, nitrate of silver, acetate and subacetate of lead, sulphate of zinc, and sulphate of iron. (*London Dispensatory.*) The medium dose is two fluidounces. W.

INFUSUM CATECHU COMPOSITUM. *U. S.* INFUSUM CATECHU. *Br. Compound Infusion of Catechu. Infusion of Catechu.*

"Take of Catechu, in fine powder, *half a troyounce;* Cinnamon, in moderately fine powder, *sixty grains;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

"Take of Catechu, in coarse powder, *one hundred and sixty grains;* Cinnamon, bruised, *thirty grains;* Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for half an hour, and strain." *Br.*

This is an elegant mode of administering catechu. The dose is from one to three fluidounces, repeated three or four times a day, or more frequently. W.

INFUSUM CHIRATÆ. *Br. Infusion of Chiretta.*

"Take of Chiretta, bruised, *a quarter of an ounce* [avoirdupois]; Distilled Water, at 120°, *ten fluidounces.* Infuse in a covered vessel, for half an hour, and strain." *Br.*

The dose of this simple bitter is from one to three fluidounces. W.

INFUSUM CINCHONÆ FLAVÆ. *U. S., Br. Infusion of Yellow Cinchona. Infusion of Yellow Bark.*

"Take of Yellow Cinchona, in moderately fine powder, *a troyounce;* Aromatic Sulphuric Acid *a fluidrachm;* Water *a sufficient quantity.* Mix the Acid with a pint of Water. Then moisten the powder with half a fluidounce of the mixture, and, having packed it firmly in a conical glass percolator, gradu-

ally pour upon it the remainder of the mixture, and afterwards Water, until the filtered liquid measures a pint." *U. S.*

"Take of Yellow Cinchona Bark, in coarse powder, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for two hours, and filter through paper." *Br.*

Though the infusion with boiling water is more quickly prepared than the cold infusion, and therefore better adapted to cases of emergency, yet the latter is a more elegant preparation, not turbid like the former, and at least equally efficient. We, therefore, prefer the process of the U. S. Pharmacopœia, provided it be skilfully conducted.

The U. S. infusion is an elegant and very efficient preparation. Water extracts from bark the kinates of quinia and cinchonia, but leaves behind the compounds which these principles form with the cinchotannic acid. The simple infusion, therefore, is rather feeble. But the addition of the acid ensures the solution of all or nearly all the active matter. We have been long in the habit of using this infusion, and have had reason to be satisfied with its efficacy. It would be best that the bark should be macerated with the acidulated water some time before being introduced into the instrument.

The infusion of cinchona, made without acid, affords precipitates with the alkalies, alkaline carbonates, and alkaline earths; the soluble salts of iron, zinc, and silver; corrosive chloride of mercury, arsenious acid, and tartar emetic; gelatinous solutions; and various vegetable infusions and decoctions, as those of galls, chamomile, columbo, cascarilla, horse-radish, cloves, catechu, orange-peel, foxglove, senna, rhubarb, valerian, and simaruba. In some instances the precipitate occurs immediately, in others not for several hours. (*London Dispensatory.*) Few, however, of these substances diminish the efficacy of the infusion, as they do not affect the active principles. The alkalies, alkaline earths, and vegetable astringents are really incompatible. As gallic, tartaric, and oxalic acids form salts with quinia of somewhat difficult solubility, the neutral and soluble gallates, tartrates, and oxalates produce in the infusion slight precipitates of corresponding salts of the alkaloids; but these are redissolved by an excess of the acid. Tartrate of antimony and potassa does not precipitate the alkaloids. Solutions of iodine are incompatible by forming with the alkaloids insoluble compounds. For an account of the chemical reactions of the infusions of different varieties of Peruvian bark, see the *Am. Journ. of Pharm.* (ix. 128).

The simple infusion of cinchona may be advantageously administered in cases which require tonic treatment, but do not call for the full powers of the bark. The acid infusion has, we believe, all the powers of cinchona itself, and may be given for the same purposes. The medium dose is two fluidounces, equivalent to a drachm of the bark, to be repeated three or four times a day as a tonic, but more frequently as an antiperiodic. W.

INFUSUM CINCHONÆ RUBRÆ. *U. S.* Infusum Cinchonæ Compositum. *U. S.* 1850. *Infusion of Red Cinchona. Compound Infusion of Peruvian Bark. Infusion of Red Bark.*

"Take of Red Cinchona, in moderately fine powder, *a troyounce;* Aromatic Sulphuric Acid *a fluidrachm;* Water *a sufficient quantity.* Mix the Acid with a pint of Water. Then moisten the powder with half a fluidounce of the mixture, and, having packed it firmly in a conical glass percolator, gradually pour upon it the remainder of the mixture, and afterwards Water, until the filtered liquor measures a pint." *U. S.*

The remarks made in relation to infusion of yellow bark are equally applicable to this. W.

INFUSUM CUSSO. *Br. Infusion of Kousso.*

"Take of Kousso, in coarse powder, *a quarter of an ounce* [avoirdupois];

Boiling Distilled Water *four fluidounces.* Infuse in a covered vessel, for fifteen minutes, without straining." *Br.*

The whole may be taken for a dose. W.

INFUSUM DIGITALIS. *U. S., Br. Infusion of Digitalis.*

"Take of Digitalis [dried leaves], in coarse powder, *sixty grains;* Tincture of Cinnamon *a fluidounce;* Boiling Water *half a pint.* Macerate the Digitalis with the Water for two hours in a covered vessel, and strain; then add the Tincture of Cinnamon, and mix." *U. S.*

"Take of Digitalis, dried, *thirty grains;* Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

The U. S. infusion is essentially the same as that employed by Withering. It affords precipitates with sulphate of iron, acetate of lead, tannic acid, and infusion of Peruvian bark. The dose is usually stated at half a fluidounce, repeated twice a day under ordinary circumstances, every eight hours in urgent cases until the system is affected. The proportion of digitalis is scarcely half as great in the British preparation, and the dose is proportionably larger. It will not escape the close observer, that the stated dose of digitalis in infusion is much larger than in substance, for which there does not appear to be a good reason. It might be safer to give only half the quantity, and increase if necessary. The British infusion has only about half the strength of ours. W.

INFUSUM DULCAMARÆ. *Br. Infusion of Dulcamara.*

"Take of Dulcamara, bruised, *one ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

The dose is one or two fluidounces three or four times a day. W.

INFUSUM ERGOTÆ. *Br. Infusion of Ergot.*

"Take of Ergot, in coarse powder, *a quarter of an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for half an hour, and strain." *Br.*

The dose of this infusion is two fluidounces for a woman in labour. W.

INFUSUM EUPATORII. *U. S. Infusion of Thoroughwort.*

"Take of Thoroughwort [the dried herb] *a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

As a tonic, this infusion should be taken cold in the dose of one or two fluidounces three or four times a day, or more frequently; as an emetic and diaphoretic, in large tepid draughts. W.

INFUSUM GENTIANÆ COMPOSITUM. *U. S., Br. Compound Infusion of Gentian.*

"Take of Gentian, in moderately coarse powder, *half a troyounce;* Bitter Orange Peel, in moderately coarse powder, Coriander, in moderately coarse powder, each, *sixty grains;* Alcohol *two fluidounces;* Water *a sufficient quantity.* Mix the Alcohol with fourteen fluidounces of Water, and, having moistened the mixed powders with three fluidrachms of the menstruum, pack them firmly in a conical percolator, and gradually pour upon them first the remainder of the menstruum, and afterwards Water, until the filtered liquid measures a pint." *U. S.*

"Take of Gentian, sliced, *a quarter of an ounce* [avoirdupois]; Bitter-Orange Peel, bruised, Coriander, each, *thirty grains;* Proof Spirit *two fluidounces;* Cold Distilled Water *eight fluidounces.* Pour the Spirit upon the dry ingredients, in a covered vessel; in two hours add the Water, and in two hours more strain through calico." *Br.*

The use of the alcohol is to assist in dissolving the bitter principle, and at the same time to contribute towards the preservation of the infusion, which, without this addition, is very apt to spoil. The dose is a fluidounce repeated three or four times a day. W.

INFUSUM HUMULI. *U. S.* Infusum Lupuli. *Br. Infusion of Hops.*

"Take of Hops *half a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Hops *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for two hours, and strain." *Br.*

The dose of this infusion is one or two fluidounces. W.

INFUSUM JUNIPERI. *U. S. Infusion of Juniper.*

"Take of Juniper, bruised, *a troyounce;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

The whole quantity made may be taken in twenty-four hours, in doses of two or three fluidounces. W.

INFUSUM KRAMERIÆ. *U. S., Br. Infusion of Rhatany.*

"Take of Rhatany, in moderately coarse powder, *a troyounce;* Water *a sufficient quantity.* Moisten the powder with half a fluidounce of Water, and, having packed it firmly in a conical glass percolator, gradually pour Water upon it until the filtered liquid measures a pint." *U. S.*

"Take of Rhatany, bruised, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

The infusion of rhatany is probably most efficient, prepared by the mode of percolation, with cold water, from the root in a state of moderately coarse powder, as directed in the U. S. process. The dose of the infusion is one or two fluidounces. W.

INFUSUM LINI COMPOSITUM. *U. S.* Infusum Lini. *Br. Compound Infusion of Flaxseed. Infusion of Linseed.*

"Take of Flaxseed *half a troyounce;* Liquorice Root, bruised, *one hundred and twenty grains;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Linseed *one hundred and sixty grains;* Fresh Liquorice Root, sliced, *sixty grains;* Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for four hours, and strain through calico." *Br.*

This is a useful demulcent drink in inflammatory affections of the mucous membrane of the lungs and urinary passages. It may be taken *ad libitum.* W.

INFUSUM MATICÆ. *Br. Infusion of Matico.*

"Take of Matico, cut small, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for half an hour, and strain." *Br.*

The dose of this infusion is two fluidounces. W.

INFUSUM PAREIRÆ. *U. S. Infusion of Pareira Brava.*

"Take of Pareira Brava, bruised, *a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The infusion of pareira brava is highly esteemed by some English practitioners as a remedy in irritation and chronic inflammation of the urinary passages, and has been found useful in catarrh of the bladder. The dose is one or two fluidounces. Brodie employed a *decoction* of the root, which he prepared by boiling half an ounce in three pints of water down to a pint, and gave in the quantity of from eight to twelve fluidounces daily. The Br. Pharmacopœia has substituted the decoction for the infusion. W.

INFUSUM PICIS LIQUIDÆ. *U. S. Infusion of Tar. Tar Water.*

"Take of Tar *a pint;* Water *four pints.* Mix them, and shake the mixture frequently during twenty-four hours. Then pour off the infusion, and filter through paper." *U. S.*

Water takes from tar a small portion of acetic acid, empyreumatic oil includ-

ing creasote, and resinous matter, acquiring a sharp empyreumatic taste, the odour of tar, and the colour of Madeira wine. Thus impregnated it is stimulant and diuretic, and may be taken in the quantity of one or two pints daily. It is also used as a wash in chronic cutaneous affections, and is said to have proved beneficial, by injection into the bladder, in some cases of chronic cystitis. W.

INFUSUM PRUNI VIRGINIANÆ. *U. S. Infusion of Wild-cherry Bark.*

"Take of Wild-cherry Bark, in moderately coarse powder, *half a troyounce;* Water [cold] *a sufficient quantity.* Moisten the powder with six fluidrachms of Water, let it stand for an hour, pack it gently in a conical glass percolator, and gradually pour Water upon it until the filtered liquid measures a pint." *U. S.*

This is a peculiarly suitable object for officinal direction, as, in consequence of the volatile nature of one of its active ingredients, and for another reason before stated (see *page* 690), it is better prepared with cold water than in the ordinary mode. The infusion of wild-cherry bark is one of the preparations to which the process of percolation or displacement is well adapted. In this way the virtues of the bark can be more rapidly and thoroughly exhausted than by maceration alone. In order to allow time for the reaction necessary to the production of the hydrocyanic acid, an hour's preliminary maceration is directed, which might perhaps be advantageously somewhat lengthened. When properly made, the infusion is beautifully transparent, has the colour of Madeira wine, and the agreeable bitterness and peculiar flavour of the bark. The dose is two or three fluidounces three or four times a day, or more frequently when a strong impression is required. W.

INFUSUM QUASSIÆ. *U. S., Br. Infusion of Quassia.*

"Take of Quassia, rasped, *one hundred and twenty grains;* Water [cold] *a pint.* Macerate for twelve hours, in a covered vessel, and strain." *U. S.*

"Take of Quassia, in chips, *sixty grains;* Cold Distilled Water *ten fluidounces.* Infuse, in a covered vessel, for half an hour, and strain." *Br.*

The proportion of Quassia directed in the former London and Edinburgh Pharmacopœias was much too small. The London infusion contained the strength of only two grains of quassia in a fluidounce, and the Edinburgh three grains; while the dose of quassia in substance is from twenty grains to a drachm, and of the extract not less than five grains. This error has been corrected in the British Pharmacopœia. Boiling water may be employed when it is desirable to obtain the preparation quickly; but cold water affords a clearer infusion. The dose is two fluidounces three or four times a day. W.

INFUSUM RHEI. *U. S., Br. Infusion of Rhubarb.*

"Take of Rhubarb, bruised, *one hundred and twenty grains;* Boiling Water *half a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

"Take of Rhubarb, in thin slices, *a quarter of an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

In order that the rhubarb may be exhausted, it should be digested with the water near the fire, at a temperature somewhat less than that of boiling water. It is customary to add some aromatic, such as cardamom, fennel-seed, or nutmeg, which improves the taste of the infusion, and renders it more acceptable to the stomach. One drachm of either of these spices may be digested in connection with the rhubarb.

This infusion may be given as a gentle laxative, in the dose of one or two fluidounces, every three or four hours, till it operates. It is occasionally used as a vehicle of tonic, antacid, or more active cathartic medicines. The stronger acids and most metallic solutions are incompatible with it. W.

INFUSUM ROSÆ COMPOSITUM. *U. S.* Infusum Rosæ Acidum. *Br. Compound Infusion of Rose. Acid Infusion of Roses.*

"Take of Red Rose [dried petals] *half a troyounce;* Diluted Sulphuric Acid *three fluidrachms;* Sugar [refined], in coarse powder, *a troyounce and a half;* Boiling Water *two pints and a half.* Pour the Water upon the Rose in a covered glass or porcelain vessel; then add the Acid, and macerate for half an hour. Lastly, strain the liquid, and in it dissolve the Sugar." *U. S.*

"Take of Red-rose Petals *a quarter of an ounce* [avoirdupois]; Dilute Sulphuric Acid *one fluidrachm;* Boiling Distilled Water *ten fluidounces.* Add the Acid to the Water, infuse the Petals in the mixture in a covered vessel, for half an hour, and strain." *Br.*

The red roses serve little other purpose than to impart a fine red colour and a slight astringent flavour to the preparation, which owes its medicinal virtues almost exclusively to the sulphuric acid. It is refrigerant and astringent, and affords a useful and not unpleasant drink in hemorrhages and colliquative sweats. It is much used by British practitioners as a vehicle for saline medicines, particularly sulphate of magnesia, the taste of which it serves to cover. It is also employed as a gargle, usually in connection with acids, nitre, alum, or tincture of Cayenne pepper. The dose is from two to four fluidounces. W.

INFUSUM SALVIÆ. *U. S. Infusion of Sage.*

"Take of Sage *half a troyounce;* Boiling Water *a pint.* Macerate for half an hour in a covered vessel, and strain." *U. S.*

This preparation is less used internally than as a gargle, or as a vehicle for other substances, such as alum, employed in this way. W.

INFUSUM SENEGÆ. *Br. Infusion of Seneka.*

"Take of Senega, bruised, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel for one hour, and strain." *Br.*

The efficacy of the officinal decoction of seneka has been proved by so long an experience, that we should be cautious in allowing it to be superseded by the infusion on hypothetical grounds. The dose of the preparation is from *one to three fluidounces.* W.

INFUSUM SENNÆ. *U. S., Br. Infusion of Senna.*

"Take of Senna *a troyounce;* Coriander, bruised, *sixty grains;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

"Take of Senna *half an ounce* [avoirdupois]; Ginger, sliced, *thirty grains;* Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for one hour, and strain." *Br.*

We prefer the coriander of the U. S. Pharmacopœia to the ginger of the British, though the reduction of the proportion of this ingredient formerly directed by the British Colleges is an improvement. This infusion deposits, on exposure to the air, a yellowish precipitate, which is said to aggravate its griping tendency; it should, therefore, not be made in large quantities. It is customary to connect with it manna and some one of the saline cathartics, which increase its efficacy, and render it less painful in its operation. The following is a good formula for the preparation of senna tea. Take of senna *half an ounce:* sulphate of magnesia, manna, each, *an ounce;* fennel-seed *a drachm;* boiling water *half a pint.* Macerate in a covered vessel till the liquid cools. One-third may be given for a dose, and repeated every four or five hours till it operates. Such a combination as this is called *the black draught* by English writers. The dose of the infusion of the U. S. Pharmacopœia is about four fluidounces.

The cold infusion, especially if made by percolation from the coarsely powdered leaves, while probably not inferior in strength to that prepared with boiling water, is said to be less unpleasant to the taste. W.

INFUSUM SERPENTARIÆ. *U. S., Br. Infusion of Serpentaria.*

"Take of Serpentaria, in moderately coarse powder, *half a troyounce;* Water *a sufficient quantity.* Moisten the powder with two fluidrachms of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the filtered liquid measures a pint.

"This Infusion may also be prepared by macerating the Serpentaria with a pint of boiling water, for two hours, in a covered vessel, and straining." *U. S.*

"Take of Serpentary *a quarter of an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel for two hours, and strain." *Br.*

This is the ordinary form in which serpentaria is employed. The dose is one or two fluidounces, repeated every two hours in low forms of fever, but less frequently in chronic affections. W.

INFUSUM SPIGELIÆ. *U. S. Infusion of Spigelia.*

"Take of Spigelia *half a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The dose of this infusion, for a child two or three years old, is from four fluidrachms to a fluidounce; for an adult, from four to eight fluidounces, repeated morning and evening. A quantity of senna equal to that of the spigelia is usually added, in order to ensure a cathartic effect. W.

INFUSUM TABACI. *U. S.* ENEMA TABACI. *Br. Infusion of Tobacco.*

"Take of Tobacco *sixty grains:* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." *U. S.*

For the mode of preparing the British *Enema Tabaci,* see page 1077.

This is used only in the form of enema in strangulated hernia, obstinate colic, and retention of urine from spasm of the urethra. Only half of the pint of the U. S. infusion should be employed at once; and, if this should not produce relaxation in half an hour, the remainder may be injected. Fatal consequences have resulted from too free a use of tobacco in this way. W.

INFUSUM TARAXACI. *U. S. Infusion of Dandelion.*

"Take of Dandelion, bruised, *two troyounces;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

This has been substituted in the U. S. Pharmacopœia for the decoction. The dose is a wineglassful two or three times a day, or oftener. W.

INFUSUM UVÆ URSI. *Br. Infusion of Bearberry.*

"Take of Bearberry Leaves *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for two hours, and strain through calico." *Br.*

The dose is one or two fluidounces three or four times a day. W.

INFUSUM VALERIANÆ. *U. S., Br. Infusion of Valerian.*

"Take of Valerian, in moderately coarse powder, *half a troyounce;* Water *a sufficient quantity.* Moisten the powder with two fluidrachms of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the filtered liquid measures a pint.

"This Infusion may also be prepared by macerating the Valerian with a pint of boiling Water, for two hours, in a covered vessel, and straining." *U. S.*

"Take of Valerian, bruised, *one hundred and twenty grains;* Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel for one hour, and strain." *Br.*

The dose of this infusion is two fluidounces, repeated three or four times a day, or more frequently. W.

INFUSUM ZINGIBERIS. *U. S. Infusion of Ginger.*

"Take of Ginger, bruised, *half a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

The dose of this infusion is two fluidounces. W

LINIMENTA.

Liniments.

These are preparations intended for external use, of such a consistence as to render them conveniently applicable to the skin by gentle friction with the hand. They are usually thicker than water, but thinner than the ointments, and are always liquid at the temperature of the body. The former officinal preparations, belonging to this class, which have been omitted in the present editions of the U. S. and Br. Pharmacopœias, are the *Liniments of Verdigris*, Lond., and of *Sesquicarbonate of Ammonia*, Lond.; the *Compound Liniment of Ammonia*, Ed.; the *Camphorated Soap Liniment*, or *Opodeldoc*, U. S.; and the *Simple Liniment*, Ed.

LINIMENTUM ACONITI. *Br. Liniment of Aconite.*

"Take of Aconite Root, in powder, *twenty ounces* [avoirdupois]; Camphor *one ounce* [avoird.]; Rectified Spirit thirty fluidounces, or *a sufficiency.* Moisten the Aconite Root with a portion of the Spirit, and macerate for seven days; then percolate into a receiver containing the Camphor, until the product amounts to one pint [Imperial measure]." *Br.*

This is a very strong tincture of aconite root, intended only for external use.* (See *Aconiti Radicis.*) It may be applied alone by means of a camel's hair pencil, or in connection with two parts or more of soap liniment or chloroform liniment, by rubbing it on the part affected. W.

LINIMENTUM AMMONIÆ. *U. S., Br. Liniment of Ammonia. Volatile Liniment.*

"Take of Water of Ammonia *a fluidounce;* Olive Oil *two troyounces.* Mix them." *U. S.*

"Take of Solution of Ammonia *one fluidounce;* Olive Oil *three fluidounces.* Mix together with agitation." *Br.*

The U. S. and British Pharmacopœias agree at present very nearly in the strength of this liniment; the U. S. preparation being somewhat the stronger. In the process, the ammonia reacts with the oil to form a soap, which is partly dissolved, partly suspended in the water, producing a white, opaque emulsion. The liniment is an excellent rubefacient, frequently employed in inflammatory affections of the throat, catarrhal and other pectoral complaints of children, and in rheumatic pains. It is applied by rubbing it gently upon the skin, or placing a piece of flannel saturated with it over the affected part. Should it occasion too much inflammation, it must be diluted with oil. W.

* A liniment of aconite has for some years been considerably employed in Philadelphia, prepared according to the following formula of Prof. Procter. Take of Aconite Root, in powder, *four troyounces*, Glycerin *two fluidrachms*, Alcohol *a sufficient quantity.* Macerate the Aconite with half a pint of Alcohol for *twenty-four hours;* then pack it in a small percolator, and gradually pour Alcohol upon it until a pint of tincture has passed. Distil off twelve fluidounces, and evaporate the residue until it measures twelve fluidrachms, to which the glycerin and two fluidrachms of alcohol are to be added, making the resulting fluid extract measure two fluidounces. Each minim of this represents two grains of the root, and, if the aconite is exhausted in the process, and nothing lost during the evaporation, both of which conditions we understand to be fulfilled in the process, the preparation is twice as strong as the British liniment. It is intended, as its name implies, only for external use. It may be used in the same manner as the liniment described in the text. (*Am. Journ. of Pharm.*, xxv. 293.)—*Note to the twelfth edition.*

LINIMENTUM BELLADONNÆ. *Br. Liniment of Belladonna.*

This is prepared from Belladonna Root precisely as the Liniment of Aconite is prepared from Aconite Root; and the same remarks are applicable as to its strength and use. (See *Linimentum Aconiti.*)

LINIMENTUM CALCIS. *U. S., Br. Lime Liniment.*

"Take of Solution of Lime *eight fluidounces;* Flaxseed Oil *seven troyounces.* Mix them." *U. S.*

"Take of Solution of Lime *two fluidounces;* Olive Oil *two fluidounces.* Mix together with agitation." *Br.*

The lime forms a soap with the oil, of which there is a great excess, that separates upon standing. Olive oil, as directed by the British Pharmacopœia, is often substituted for that of flaxseed, but possesses no other advantage than that of having a less unpleasant odour. This is a very useful liniment in recent burns and scalds. It is sometimes called *Carron oil,* from having been much employed at the Carron iron works in Scotland. It is recommended to be applied upon some carded cotton. W.

LINIMENTUM CAMPHORÆ. *U. S., Br. Liniment of Camphor.*

"Take of Camphor *three troyounces;* Olive Oil *twelve troyounces.* Dissolve the Camphor in the Oil." *U. S.*

"Take of Camphor *one ounce* [avoirdupois]; Olive Oil *four fluidounces.* Dissolve the Camphor in the Oil." *Br.*

This is employed as an anodyne embrocation in sprains, bruises, rheumatic or gouty affections of the joints, and other local pains. It is also supposed to have a discutient effect when rubbed upon glandular swellings.

Mr. Wm. B. Price, of Burlington, N. J., proposes a modification of this liniment, founded on the solvent power of chloroform over camphor, whereby the preparation is made stronger with camphor, and acquires also additional anodyne influence from the chloroform. The proposed liniment consists of *an ounce and a half* of camphor, *two fluidrachms* of chloroform, and *two fluidounces* of olive oil. It is useful in rheumatic and neuralgic pains. (*N. J. Med. Reporter,* ii. 217.)

Off. Prep. Linimentum Chloroformi, *Br.;* Linimentum Hydrargyri, *Br.;* Linimentum Terebinthinæ Aceticum, *Br.* W.

LINIMENTUM CAMPHORÆ COMPOSITUM. *Br. Compound Liniment of Camphor.*

"Take of Camphor *two ounces and a half* [avoirdupois]; English Oil of Lavender *one fluidrachm;* Strong Solution of Ammonia *five fluidounces;* Rectified Spirit *fifteen fluidounces.* Dissolve the Camphor and Oil of Lavender in the Spirit; then add the Solution of Ammonia gradually, with agitation, until the whole is dissolved." *Br.*

This is used as a rubefacient and at the same time anodyne embrocation in local pains, particularly of a rheumatic character. W.

LINIMENTUM CANTHARIDIS. *U. S., Br. Liniment of Cantharides.*

"Take of Cantharides, in fine powder, *a troyounce;* Oil of Turpentine *half a pint.* Digest the Cantharides with the Oil for three hours in a close vessel, by means of a water-bath, and strain." *U. S.*

"Take of Cantharides, in powder, *eight ounces* [avoirdupois]; Acetic Acid *four fluidounces;* Ether *one pint* [Imperial measure]. Macerate the Cantharides in the Acetic Acid for twenty-four hours; then place in a percolator, and allow the Ether to pass slowly through till twenty fluidounces are obtained. Keep it in a stoppered bottle." *Br.*

Oil of turpentine dissolves, especially with the aid of heat, the active principle

of cantharides, and, when impregnated with it, acquires in addition to its own rubefacient properties those of a powerful epispastic. The U. S. liniment was introduced into notice by the late Dr. Joseph Hartshorne, of Philadelphia, who employed it with advantage as an external stimulant in the prostrate states of typhus fever. Caution, however, is necessary in its use, both to graduate its strength to the circumstances of the case, and not to apply it very extensively, lest it may produce troublesome, if not dangerous vesication. If too powerful, it may be diluted with olive or linseed oil. The British preparation is a solution of the active matter of the flies in acetic acid and ether, and, as the ether must quickly evaporate, conjoins the influence of the cantharides and the acid. W.

LINIMENTUM CHLOROFORMI. *U.S., Br. Liniment of Chloroform.*

"Take of Purified Chloroform *three troyounces;* Olive Oil *four troyounces.* Mix them." *U. S.*

"Take of Chloroform *two fluidounces;* Liniment of Camphor *two fluidounces.* Mix." *Br.*

This is an excellent local application in painful affections, though the common commercial chloroform would have answered quite as well as the purified, directed in the U. S. formula. As the chloroform rapidly evaporates, it is desirable, in order to obtain its full anodyne effect, to guard against this by oiled silk or some other impermeable covering. As some object to the greasy residue left on the skin by the evaporation of the chloroform, the soap liniment, which can readily be removed with a little warm water, may be substituted for the olive oil of the U. S., or the camphor liniment of the British preparation. W.

LINIMENTUM CROTONIS. *Br. Liniment of Croton Oil.*

"Take of Croton Oil *half a fluidounce;* Olive Oil *three fluidounces and a half.* Mix." *Br.*

This is a pustulating preparation, operating somewhat slowly. From ten to thirty minims or more may be rubbed upon a limited surface, and repeated twice a day or oftener till an eruption is produced. W.

LINIMENTUM HYDRARGYRI. *Br. Liniment of Mercury.*

"Take of Ointment of Mercury *one ounce* [avoirdupois]; Solution of Ammonia, Liniment of Camphor, each, *one fluidounce.* Liquefy the Ointment of Mercury in the Liniment of Camphor, with a gentle heat, then add the Solution of Ammonia, and mix with agitation." *Br.*

This is a stimulating liniment, employed for the discussion of chronic glandular enlargements, swellings of the joints, and venereal tumours, and to promote the absorption of collections of fluid. It is said to be more apt to salivate than mercurial ointment. One drachm of it may be rubbed upon the affected part night and morning. W.

LINIMENTUM IODI. *Br. Liniment of Iodine.*

"Take of Iodine *one ounce and a quarter* [avoirdupois]; Iodide of Potassium *half an ounce* [avoird.]; Rectified Spirit *five fluidounces.* Dissolve the Iodine and Iodide of Potassium in the Spirit." *Br.*

This is a very strong alcoholic solution of iodine, in which the iodide of potassium acts by increasing the solubility of the active ingredient. See for its effects the article on Iodine in the first part of this work. W.

LINIMENTUM OPII. *Br. Liniment of Opium. Anodyne Liniment.*

"Take of Tincture of Opium, Liniment of Soap, each, *two fluidounces.* Mix." *Br.*

This is commonly called *anodyne liniment,* and is employed as an anodyne and gently rubefacient embrocation in sprains, bruises, and rheumatic and gouty pains. We are informed that the preparation which has commonly been used, under the name of *anodyne liniment,* in this city, is that of the late London

Pharmacopœia, as given in former editions of the U. S. Dispensatory, consisting of one part by measure of tincture of opium and three of soap liniment, and consequently having only half the opiate strength of the present British liniment. W.

LINIMENTUM SAPONIS. *U. S.*, *Br.* *Soap Liniment.* TINCTURA SAPONIS CAMPHORATA. *U. S.* 1850. *Camphorated Tincture of Soap.*

"Take of Soap, in shavings, *four troyounces;* Camphor *two troyounces;* Oil of Rosemary *half a fluidounce;* Water *four fluidounces;* Alcohol *two pints.* Mix the Alcohol and Water, digest the Soap with the mixture, by means of a water-bath, until it is dissolved; then filter, and, having added the Camphor and Oil, mix the whole thoroughly together." *U. S.*

"Take of Hard Soap *two ounces and a half* [avoirdupois]; Camphor *one ounce and a quarter* [avoird.]; English Oil of Rosemary *three fluidrachms;* Rectified Spirit *eighteen fluidounces;* Distilled Water *two fluidounces.* Mix the Water with the Spirit, and add the Oil of Rosemary, the Soap, and the Camphor. Digest at a temperature not exceeding 70°, with occasional agitation, until all are dissolved." *Br.*

It is necessary, in preparing this liniment, that the soap employed should not have been made with animal oil, as otherwise the preparation will not be fluid at ordinary temperatures. The soap indicated by the U. S. Pharmacopœia is that "prepared from soda and olive oil," commonly called *Castile soap.* Made according to the directions of the U. S. Pharmacopœia of 1840, the tincture was unable to retain the soap in solution, and therefore coagulated more or less on cooling. This defect was corrected in the edition of 1850, by the addition of water; and a similar reformation has been made in the British process.

In former editions of the U. S. Pharmacopœia, this preparation, though commonly called *Soap liniment,* received the name of *Tinctura Saponis Camphorata,* to distinguish it from a similar preparation called *Opodeldoc,* which, having a soft semi-solid consistence, was introduced with the title of *Linimentum Saponis Camphoratum.* This, having been discarded at the late revision, the Tincture reverted to its place among the liniments, and is now called simply Linimentum Saponis. But, as the old Camphorated Soap Liniment or *Opodeldoc* is an excellent preparation, and still somewhat in use, we give here the process of the Pharmacopœia of 1850 for its preparation, with some remarks on the subject.

"Take of Common Soap, sliced, *three ounces;* Camphor *an ounce;* Oil of Rosemary, Oil of Origanum, each, *a fluidrachm;* Alcohol *a pint.* Digest the Soap with the Alcohol, by means of a sand-bath, till dissolved; then add the Camphor and Oils, and when they are dissolved, pour the liquor into broad-mouthed bottles. This liniment has, when cold, the consistence of a soft ointment."

This preparation differs from the officinal Linimentum Saponis chiefly in being prepared with common white soap, made with animal fat, instead of Castile soap, which is made of olive oil. The former is peculiarly adapted to the purposes of this formula, in consequence of assuming, when its alcoholic solution cools, the consistence characteristic of the liniment. It is customary, after the solution of the soap has been effected, to pour the liquor into small wide-mouthed glass bottles, containing about four fluidounces, in which it concretes into a soft, translucent, uniform, yellowish-white mass. This liniment melts with the heat of the body, and therefore becomes liquid when rubbed on the skin.

The Soap liniment is much used, as an anodyne and gently rubefacient embrocation, in sprains, bruises, and rheumatic or gouty pains.

Off. Prep. Linimentum Opii, *Br.* W.

LINIMENTUM TEREBINTHINÆ. *U. S.*, *Br.* *Liniment of Turpentine.*

"Take of Resin Cerate *twelve troyounces;* Oil of Turpentine *half a pint.* Add the Oil to the Cerate previously melted, and mix them." *U. S.*

"Take of Oil of Turpentine *five fluidounces;* Ointment of Resin *eight ounces* [avoirdupois]. Melt the Ointment of Resin, then add the Oil of Turpentine gradually, and stir until a uniform liniment is obtained." *Br.*

This preparation is the liniment originally proposed by Dr. Kentish, and subsequently so highly lauded as a remedy in burns and scalds. It should be applied as soon after the occurrence of the accident as possible, and should be discontinued when the peculiar inflammation excited by the fire is removed. The best mode of application is to cover the burnt or scalded surface with pledgets of patent lint saturated with the liniment. It should not be allowed to come in contact with the sound parts. This liniment may also be successfully applied in other cases of cutaneous inflammation requiring stimulation, as in certain conditions of erysipelas. W.

LINIMENTUM TEREBINTHINÆ ACETICUM. *Br. Liniment of Turpentine and Acetic Acid.*

"Take of Oil of Turpentine *one fluidounce;* Acetic Acid *one fluidounce;* Liniment of Camphor *one fluidounce.* Mix." *Br.*

This is a powerful rubefacient liniment, combining the irritant properties of the oil of turpentine and acetic acid, though somewhat diluted by the camphor liniment. W.

LIQUORES.

Solutions.

The U. S. Pharmacopœia includes, in this class of preparations, all *aqueous* solutions in which the substance acted on is wholly soluble in water, excluding those in which the dissolved matter is gaseous or very volatile, as in the Aquæ or Waters. The *Solution of Gutta-percha* is the only one in which water is not used as the menstruum; and that seems to have been placed in the present category, because no better position could be found for it.

In the British Pharmacopœia it has been deemed expedient, in almost all instances in which the substance to be dissolved is an isolated solid body, to make the solutions of uniform strength, without regard to the physiological powers of the medicine, or its ordinary dose. The solutions of this kind contain four grains of the medicine to an Imperial fluidounce of the menstruum, or half a grain in a fluidrachm. There is a convenience in this plan to the prescriber, in relation to all medicines which habitually present themselves to his mind in the solid state; but to alter the strength of a solution which has been long known, and the dose of which is familiar, in order to make it conform with others, is to endanger frequent serious errors for the sake of an idea. In such medicines, for example, as Fowler's solution, the dose is fixed in the mind of the practitioner in reference to the solution, and not to the solid medicinal substance it may contain. On the whole, therefore, we prefer the method of the U. S. Pharmacopœia, which regulates the strength of its solutions in regard to the properties of the medicine, and not in accordance with an ideal standard.

Though several of the solutions have long been officinal, it is now for the first time that, in both Pharmacopœias, they have been dislocated from their old attachments, and arranged together as a distinct class of preparations. W.

LIQUOR AMMONIÆ ACETATIS. *U. S., Br.* SPIRITUS MINDERERI. *Solution of Acetate of Ammonia. Spirit of Mindererus.*

"Take of Diluted Acetic Acid *two pints;* Carbonate of Ammonia *a sufficient quantity.* Add the Carbonate gradually to the Acid until this is saturated, and filter. This preparation, when dispensed, should be freshly made." *U. S.*

"Take of Strong Solution of Ammonia *three fluidounces and a half,* or *a sufficiency;* Acetic Acid *ten fluidounces,* or *a sufficiency.* Mix gradually, and,

if the product is not neutral to test paper, make it so by the addition of the proper quantity of either liquid." *Br.*

This preparation is an aqueous solution of acetate of ammonia. The U. S. process by which it is formed constitutes a case of single elective affinity. The acetic acid combines with the ammonia of the carbonate, forming the acetate of ammonia, and disengages the carbonic acid with effervescence. Distilled vinegar was formerly used, but has been abandoned for diluted acetic acid, which is much to be preferred; because, besides furnishing a solution of the acetate of uniform strength, a result which cannot be attained by the employment of distilled vinegar, it avoids the production of a brownish solution, which uniformly follows the use of the latter, especially when it has been condensed in a metallic worm. The quantity of carbonate of ammonia, necessary to saturate a given weight of the acid of average strength, cannot be laid down with precision, on account of the variable quality of the salt. The preparation, when made with the diluted acetic acid of the U. S. Pharmacopœia, contains about 6 per cent. of acetate of ammonia. It is more convenient to add the salt to the acid than the acid to the salt; as the point of saturation is thus more easily attained. In ascertaining this point by test-paper, the alkaline reaction will begin, though a portion of free acetic acid may still remain; a little of it being insufficient to overcome the natural alkaline reaction of the salt. (See *page* 21.) A complication is caused by the presence of free carbonic acid, which may be expelled from the liquid towards the end of the saturation by warming it. Supposing the carbonic acid got rid of, the best rule, perhaps, is to cease adding the carbonate of ammonia, upon the occurrence of the least sign of alkalinity.

In the British process the ammonia combines directly with the acetic acid, without other reaction. The solution is much stronger than that of the U. S. Pharmacopœia, or of the former Pharmacopœias of Great Britain, being made with stronger solution of ammonia and undiluted acetic acid, probably because it keeps better when thus made. To reduce it to the strength of the U. S. preparation, it would require to be diluted with about four measures of distilled water. There is an advantage in the British process in the use of ammonia instead of its carbonate; as the difficulty of ascertaining the precise point of saturation arising from carbonic acid is avoided; but in this solution, as in the neutral mixture, a great benefit remedially is gained by the presence of that acid, which reconciles the stomach to the medicine, and sometimes even allays vomiting in febrile diseases. With this view of the subject, it is better to use the carbonate of ammonia, and to prepare the solution without heating it in order to drive off the acid, even though thereby there might be some risk of a slight excess of one of the constituents.

Properties. Solution of acetate of ammonia, when made of pure materials, is a limpid and colourless liquid without smell. Its taste is saline, and resembles that of a mixture of nitre and sugar. When it contains an excess of alkali, its taste is bitterish. It should be freshly prepared at short intervals; as its acid becomes decomposed, and a portion of carbonate of ammonia is generated. As formerly prepared, under the name of *spiritus Mindereri*, it was made from the impure carbonate of ammonia containing animal oil, which modified the preparation by giving rise to a portion of ammoniacal soap. When pure it is not coloured by hydrosulphuric acid, nor precipitated by chloride of barium. Nitrate of silver precipitates crystals of acetate of silver, soluble in water, and especially in nitric acid. An insoluble precipitate with this test is chloride of silver, and shows the presence of muriatic acid. Potassa disengages ammonia; sulphuric acid, acetous vapours. When evaporated to dryness, the residue is wholly dissipated by heat with the smell of ammonia. It is incompatible with acids, the fixed alkalies and their carbonates, lime-water, magnesia, sulphate of magnesia, corrosive sublimate, the sulphates of iron, copper, and zinc, and nitrate of silver.

When it contains free carbonic acid, it produces with the acetate or subacetate of lead a precipitate of carbonate of lead, which, being mistaken for the sulphate, has sometimes led to the erroneous conclusion that sulphuric acid was present in the distilled vinegar, when this has been employed. Acetate of ammonia is a salt of difficult crystallization, and very deliquescent. When perfect it probably has an alkaline reaction, like the acetates of potassa and soda. It may be obtained by sublimation from a mixture of equal parts of dry acetate of potassa or of lime, and muriate of ammonia. It consists of one eq. of acetic acid 51, and one of ammonia 17 = 68, with seven eqs. of water 63, when crystallized. It may be viewed as acetate of oxide of ammonium, containing six eqs. of water.

Medical Properties and Uses. Solution of acetate of ammonia is a valuable diaphoretic, much employed in febrile and inflammatory diseases. According to the indications to be answered by its use, it is variously combined with nitre and antimonials, camphor and laudanum. If, instead of promoting its determination to the skin by external warmth, the patient walk about in a cool air, its action will be directed to the kidneys. In large doses, it is said to relieve painful menstruation. It is sometimes used externally as a discutient. Mr. Braude speaks of it as very useful in mumps, applied hot upon a piece of flannel. In the hydrocele of children, it is strongly recommended by Dr. Maushner, applied by means of compresses kept constantly moist. Mixed in the quantity of a fluidounce with seven fluidounces of rose-water, and two fluidrachms of laudanum, it forms a useful collyrium in chronic ophthalmia. The late Dr. A. T. Thomson used it as a lotion with good effect in porrigo affecting the scalp. The dose of the U. S. preparation is from half a fluidounce to a fluidounce and a half, every three or four hours, mixed with water and sweetened with sugar. It proves sometimes very grateful to febrile patients, when prescribed with an equal measure of carbonic acid water.

Of the Br. solution the sp. gr. is 1·06; and one fluidounce treated with excess of muriatic acid, and evaporated to dryness by a water-bath, leaves a residue of muriate of ammonia weighing 100 grains. It is directed in the Pharmacopœia to have no action on litmus, and not to be rendered turbid by lime-water; the former test indicating its neutrality, the latter the absence of free carbonic acid or a carbonate. It is very important not to confound the British solution with our own, as the dose is much smaller, being only, for ordinary purposes, from thirty minims to a fluidrachm, which should be largely diluted with water. B.

LIQUOR ANTIMONII TERCHLORIDI. *Br. Solution of Terchloride of Antimony.*

"Take of Prepared Sulphuret of Antimony *one pound* [avoirdupois]; Commercial Hydrochloric Acid *four pints* [Imperial measure]. Place the Sulphuret of Antimony in a porcelain vessel, pour upon it the Hydrochloric Acid, and, constantly stirring, apply to the mixture, beneath a flue with a good draught, a gentle heat, which must be gradually augmented as the evolution of gas begins to slacken, until the liquid boils. Maintain it at this temperature for fifteen minutes; then remove the vessel from the fire, and filter the liquid through calico into another vessel, returning what passes through first, that a perfectly clear solution may be obtained. Boil this down to the bulk of two pints [Imp. meas.], and preserve it in a stoppered bottle." *Br.*

When tersulphuret of antimony is dissolved with the aid of heat in muriatic acid, a double decomposition takes place, resulting in the formation of terchloride of antimony and hydrosulphuric acid (sulphuretted hydrogen), which gives rise to effervescence. As this gas is exceedingly offensive and deleterious, the materials, during the reaction, are directed to be placed under a flue with a good draught. When the reaction is over, the resulting aqueous solution of terchloride, after having been strained, is boiled down to a determinate volume.

Properties. Solution of terchloride of antimony is a transparent, pale-yellow,

dense liquid, possessing caustic properties. When of a deep-red colour, it is impure from the presence of iron. Its sp. gr., concentrated to the extent directed in the Br. Pharmacopœia, is 1·470. "A little of it dropped into water gives a white precipitate, and the filtered solution lets fall a copious deposit on the addition of nitrate of silver. If the white precipitate formed by water be treated with sulphuretted hydrogen it becomes orange." (*Br.*) These reactions show that it contains antimony and chlorine. A fluidrachm of it, mixed with four fluidounces of water in which are dissolved 110 grains of tartaric acid, forms a clear solution, from which sulphuretted hydrogen throws down an orange precipitate (tersulphuret of antimony), weighing, when washed and dried at 212°, at least 22 grains. (*Br.*) When it is distilled, water, the excess of muriatic acid, and any tersulphuret of arsenic that may happen to be present, are first expelled, and afterwards the terchloride volatilizes. The pure terchloride may be obtained by changing the receiver, as soon as the distilled product concretes on cooling Pure terchloride of antimony, called by the earlier chemists *butter of antimony*, is a white, readily fusible solid, of the consistence of butter, deliquescent and powerfully caustic, and volatilizable under an obscure red heat. It was formerly used in medicine as a caustic. It usually acts without causing much pain or inflammation; and, after the separation of the eschar, a clean, healthy ulcer is left.

Solution of terchloride of antimony was a new officinal of the Dublin Pharmacopœia of 1850, and is probably retained in the British not as a therapeutic agent, but simply as a source of the officinal oxide of antimony.

Off. Prep. Antimonii Oxidum, *Br.* B.

LIQUOR ARSENICI ET HYDRARGYRI IODIDI. *U. S.* *Solution of Iodide of Arsenic and Mercury. Solution of Hydriodate of Arsenic and Mercury. Donovan's Solution.*

"Take of Iodide of Arsenic, Red Iodide of Mercury, each, *thirty-five grains;* Distilled Water *half a pint.* Rub the Iodides with half a fluidounce of the Water, and, when they have dissolved, add the remainder of the Water, and filter through paper." *U. S.*

This solution was introduced to the notice of the medical profession in 1839, by Mr. Donovan, of Dublin, as a therapeutic agent combining the medical virtues of its three ingredients, and was adopted as an officinal preparation in the U. S. and Dublin Pharmacopœias of 1850. The former has retained it in the present edition; but, on the absorption of the latter in the British Pharmacopœia, it was discarded. The formula of the U. S. Pharmacopœia is the simplified one of Prof. Procter, which consists essentially in dissolving equal weights of the teriodide of arsenic and biniodide (red iodide) of mercury in a measured quantity of distilled water. The proportion of equal weights corresponds nearly to single equivalents of the component iodides. The Dublin formula was more complicated. In it the proper quantities of arsenic, mercury, and iodine were caused to unite by first rubbing them together with alcohol, and then boiling the product with distilled water, which was afterwards added, so as to give the whole a determinate bulk. The iodides of arsenic and mercury, formed by the trituration, were assumed by Mr. Donovan to become, by solution, hydriodates severally of arsenious acid (white oxide of arsenic), and of deutoxide of mercury (red precipitate).

Properties. This solution has a pale-yellow colour, and a slightly styptic taste. Sometimes, however, the colour is orange-yellow, owing to the presence of free iodine. This may be neutralized by rubbing the solution with a little metallic mercury or arsenic, in fine powder, and the proper hue thus restored. The solution is incompatible with laudanum, and the soluble salts of morphia. On the supposition that it is an aqueous solution of iodides, it will contain them in the proportion of one eq. of teriodide of arsenic 453·9 to one of biniodide of mer-

cury 452·6, which are nearly equal weights. On the theory of their conversion into hydriodates by solution, five eqs. of water 45 would be required, three for the arsenical teriodide, and two for the mercurial biniodide; and the result would be one eq. of arsenious acid 99, one of deutoxide of mercury 216, and five of hydriodic acid 636·5, the latter containing five eqs. of iodine 631·5. The solution here supposed would contain about two and one-sixth times as much deutoxide of mercury as of arsenious acid.

Medical Properties. This preparation has been found decidedly useful as an alterative in various diseases of the skin, such as the different forms of psoriasis, impetigo, porrigo, lepra, pityriasis, lupus, and venereal eruptions, both papular and scaly. In support of its efficacy in these affections, Mr. Donovan has adduced the testimony of a number of respectable practitioners, who have communicated to him the results of their experience. The disease in some of the cases cured had existed for several years. Many American physicians also have used it advantageously in cutaneous diseases, and found more marked and prompt effects from it than from the remedies usually resorted to. The dose is from five to twenty drops three times a day, given preferably in distilled water. The latter dose contains the twenty-fourth of a grain of arsenious acid, a little over the twelfth of a grain of deutoxide of mercury, and about a quarter of a grain of iodine. Dr. E. I. Taylor, of New York, who has employed it in many cases, never exceeded five drops, three times a day. Sometimes the medicine deranges the stomach, confines the bowels, and causes headache, giddiness, and confusion of mind. When these effects are produced, it must be laid aside, and a purgative administered. After an interval varying from ten days to three weeks, it may be resumed, but in a smaller dose. The treatment must often be persevered in for several months. Sometimes the medicine produces moderate salivation. The solution, diluted with an equal bulk of water, has occasionally been used with advantage as an application to the ulcers or eruptions, at the same time that it was given internally. (See three papers by Mr. Donovan, contained in the *Dublin Journal of Medical Science* for Nov. 1839, Sept. 1840, and Nov. 1842.) B.

LIQUOR ATROPIÆ. *Br.* *Solution of Atropia.*

"Take of Atropia, in crystals, *four grains;* Rectified Spirit *one fluidrachm;* Distilled Water *seven fluidrachms.* Mix the Spirit and the Water, and dissolve the Atropia in the mixture." *Br.*

For the effects of this solution, see Atropia. If given internally the dose to begin with should not exceed four minims. But, as we have in the extract of belladonna a preparation which may generally be depended on for obtaining the effects of the medicine, it seems hardly advisable to make use internally of so powerful and dangerous a preparation. It may be applied to the eye for dilating the pupil, or injected into the subcutaneous tissue for obtaining the effects of Belladonna on the system. W.

LIQUOR BARII CHLORIDI. *U. S.* *Solution of Chloride of Barium. Solution of Muriate of Baryta.*

"Take of Chloride of Barium *a troyounce;* Distilled Water *three fluidounces.* Dissolve the Chloride in the Distilled Water, and filter through paper." *U. S.*

This has been omitted from the list of preparations in the British Pharmacopœia, but is contained in the Appendix as a test solution.

Chloride of barium, not being used in the solid state, is here dissolved for convenience in prescribing. The solution is nearly saturated, and is probably too strong for convenient use. It should be limpid and colourless; and, to make it so, the salt in crystals, and not in powder, should be employed.

Medical Properties and Uses. This solution is deobstruent and anthelmintic, and in large doses poisonous; its action, according to some, being analogous to

that of arsenic. It was introduced into practice by Dr. Crawford as a remedy for cancer and scrofula. Its value in the latter disease has been insisted on by Hufeland. This physician considers it to act more particularly on the lymphatic system, in the irritated states of which he esteems it a valuable remedy. Hence he recommends it in the scrofulous affections of delicate and irritable organs, such as the eyes, lungs, &c. In the commencement of scrofulous phthisis, he views it as one of the best remedies to which we can have recourse. It is also employed in diseases of the skin, in ulcers, and ophthalmia. The dose for an adult of the U. S. solution is about five drops, given twice or thrice a day, and gradually but cautiously increased, until it produces nausea, or some other sensible impression. When taken in an overdose it causes violent vomiting and purging, vertigo, and other dangerous symptoms. To combat its poisonous effects, recourse must be had immediately to a weak solution of sulphate of magnesia, which acts by converting the poison into the insoluble sulphate of baryta. If vomiting does not come on, it should be induced by tickling the fauces, or by the administration of an emetic. A case of poisoning by three drachms of the solid salt, taken by mistake for sulphate of magnesia, was successfully treated with dilute sulphuric acid and castor oil, by Dr. C. Wolf, a German physician. The chief symptoms were tormina and vomiting, weak and irregular pulse, cold extremities, weak voice, want of muscular power in the hands and feet, and paralysis of the left eyelid.

LIQUOR CALCII CHLORIDI. *U. S. Solution of Chloride of Calcium. Solution of Muriate of Lime.*

"Take of Marble, in small pieces, *six troyounces;* Muriatic Acid *twelve troyounces;* Distilled Water *a sufficient quantity.* Mix the Acid with half a pint of Distilled Water, and gradually add the Marble. Towards the close of the effervescence apply a gentle heat, and, when the action has ceased, pour off the clear liquid and evaporate to dryness. Dissolve the residue in one and a half times its weight of Distilled Water, and filter through paper." *U. S.*

This is not included among the preparations of the British Pharmacopœia, but is placed in the Appendix as a test solution.

By the above process chloride of calcium is first formed, and then dissolved in a certain proportion of water. The solution contains 1 part of the chloride in about 2·5 parts.

The solution of chloride of calcium has a disagreeable, bitter, acrid taste. It is decomposed by sulphuric acid and the soluble sulphates; by potassa, soda, and their carbonates; by carbonate of ammonia, tartrate of potassa and soda, nitrate of silver, nitrate and acetate of mercury, and acetate of lead. The mode of preparing chloride of calcium, and its chemical properties, are detailed under the head of *Calcii Chloridum* in the first part of this work.

Medical Properties and Uses. Chloride of calcium is considered tonic and deobstruent, and is said to promote the secretion of urine, perspiration, and mucus. It was first brought into notice as a remedy by Fourcroy, and was at one time much used in scrofulous diseases and goitre. It still continues in favour with some physicians, but is less employed than formerly. It has been especially recommended in tabes mesenterica. Cazenave has employed it advantageously in chronic eczema and impetigo, connected with a lymphatic temperament. When too largely taken it sometimes occasions nausea, vomiting, and purging, and in excessive doses may even produce fatal effects; but it is a much safer remedy than chloride of barium, which has been recommended in the same complaints. The dose of the solution is from thirty minims or drops to a fluidrachm, to be repeated twice or three times a day, and gradually increased to two, three, or even four fluidrachms. It may be given in milk or sweetened water.

Off. Prep. Calcis Carbonas Præcipitata, *U. S.* W.

LIQUOR CALCIS. *U. S.*, *Br.* *Solution of Lime. Lime-water.*

"Take of Lime *four troyounces;* Distilled Water *eight pints.* Upon the Lime, first slaked with a little of the Distilled Water, pour the remainder, and stir them together. Then immediately cover the vessel, and set it aside for three hours. Keep the solution, together with the undissolved Lime, in a well-stopped bottle, and pour off the clear liquor when wanted for use. Water free from saline or other obvious impurity, though not distilled, may be employed in this process." *U. S.*

"Take of Slaked Lime *two ounces* [avoirdupois]; Distilled Water *one gallon* [Imperial measure]. Introduce the Lime into a stoppered bottle containing the Water; and shake well for two or three minutes. After twelve hours the excess of lime will have subsided, and the clear solution may be drawn off with a syphon as it is required for use, or transferred to a green-glass bottle furnished with a well-ground stopper. When the whole of the solution has been withdrawn from the bottle in which it was made, a fresh solution may be obtained by shaking the sediment at the bottom of the bottle with another gallon of Distilled Water; and, if the lime be pure, and the bottle accurately stopped, the process may be repeated four or five times." *Br.*

A solution of lime in water is the result of these processes. By the slaking of the lime it is reduced to powder, and rendered more easily diffusible through the water. According to both Pharmacopœias, the solution is to be kept in bottles with a portion of undissolved lime, which causes it always to be saturated, whatever may be the temperature, and to whatever extent it may be exposed to the air. If care be taken to have a considerable quantity of the solution in the bottle, and to avoid unnecessary agitation, the upper portion will always remain sufficiently clear for use. The repetition of the process, suggested in the Br. Pharmacopœia, cannot, of course, be carried into effect indefinitely. By the absorption of carbonic acid, the lime is gradually converted into the carbonate, and thus rendered insoluble. The employment of distilled water as the solvent may seem a useless refinement; and it certainly is unnecessary when pure spring or river water is attainable; but in many places the common water is very impure, and wholly unfit for a preparation, one of the most frequent uses of which is to allay irritation of stomach. Water dissolves but a minute proportion of lime, and, contrary to the general law, less when hot than cold. Hence the propriety of employing cold water in the process. According to Mr. Phillips, a pint of water (the wine pint of the U. S. Pharm.) at 212° dissolves 5·6 grains of lime, at 60°, 9·7 grains, and at 32°, 11·0 grains. When a cold saturated solution is heated, a deposition of lime takes place.

Properties. Lime-water is colourless, inodorous, and of a disagreeable alkaline taste, changes vegetable blues to green, and forms an imperfect soap with oils. Exposed to the air it attracts carbonic acid, and becomes covered with a pellicle of insoluble carbonate of lime, which, subsiding after a time, is replaced by another, and so on successively till the whole of the lime is exhausted. Hence the necessity of keeping lime-water either in closely corked bottles which should be full, or, what is more convenient, in bottles with an excess of lime. "Ten fluid-ounces of it require for neutralization at least twenty measures of the *volumetric solution of oxalic acid.*" *Br.*

Medical Properties and Uses. Lime-water is antacid, tonic, and astringent, and is very usefully employed in dyspepsia with acidity of stomach, diarrhœa, diabetes, and gravel attended with superabundant secretion of uric acid. Mixed with an equal measure of milk, which completely covers its offensive taste, it is one of the best remedies in our possession for nausea and vomiting dependent on irritability of stomach. We have found a diet exclusively of lime-water and milk to be more effectual than almost any other plan of treatment in dyspepsia accompanied with vomiting of food. In this case, one part of the solution to

two or three parts of milk is usually sufficient. Lime-water is also thought to be useful by dissolving the intestinal mucus in cases of worms, and in other complaints connected with an excess of this secretion. Externally it is employed as a wash in tinea capitis and scabies, as an application to foul and gangrenous ulcers, as an injection in leucorrhœa and ulceration of the bladder or urethra, and, mixed with linseed or olive oil, as a liniment in burns and scalds. The dose is from two to four fluidounces several times a day. When employed to allay nausea, it is usually given in the dose of a tablespoonful mixed with the same quantity of new milk, and repeated at intervals of half an hour, an hour, or two hours. If too long continued it debilitates the stomach.

Pharm. Uses. In preparing Argenti Oxidum, *Br.*

Off. Prep. Linimentum Calcis. W.

LIQUOR CALCIS CHLORATÆ. *Br. Solution of Chlorinated Lime.*

"Take of Chlorinated Lime *one pound* [avoirdupois]; Distilled Water *one gallon* [Imperial measure]. Mix well the Water and the Chlorinated Lime by trituration in a large mortar, and, having transferred the mixture to a stoppered bottle, let it be well shaken several times for the space of three hours. Pour out now the contents of the bottle on a calico filter, and let the solution which passes through be preserved in a stoppered bottle. The sp. gr. of this liquid is 1·035." *Br.*

For the properties and uses of this preparation, see *Calx Chlorinata*, page 185. The British Pharmacopœia gives the following test of its strength. "One fluidrachm mixed with twenty grains of iodide of potassium dissolved in four fluidounces of water, when acidulated with two fluidrachms of hydrochloric acid, gives a red solution, which requires for the discharge of its colour forty-six measures of the *volumetric solution of hyposulphite of soda.*" This determines its strength in chlorine, by determining the quantity of iodine which the chlorine contained in it is capable of separating from iodide of potassium. Notwithstanding, however, that a test of its character is thus given by the Pharmacopœia, its strength must vary according to the quality of the chlorinated lime employed. It is one of the best antidotes for hydrosulphuric acid, hydrosulphate of ammonia, sulphuret of potassium, and hydrocyanic acid. The dose for internal use is from twenty minims to a fluidrachm. For external application the solution may be diluted with twice its bulk of water, or may be used of the full strength in some cutaneous affections. W.

LIQUOR CALCIS SACCHARATUS. *Br. Saccharated Solution of Lime.*

"Take of Slaked Lime *one ounce* [avoirdupois]; Refined Sugar, in powder, *two ounces* [avoird.]; Distilled Water *one pint* [Imperial measure]. Mix the Lime and the Sugar by trituration in a mortar. Transfer the mixture to a bottle containing the Water, and, having closed this with a cork, shake it occasionally for a few hours. Finally separate the clear solution with a siphon, and keep it in a stoppered bottle. The sp. gr. is 1·052. One fluidounce requires for neutralization 25·4 measures of the standard solution of oxalic acid, which corresponds to 7·11 grains of lime." *Br.*

Lime appears to form a combination with sugar which is much more soluble than the lime itself, so that in this way we can obtain a much stronger solution of lime than by the instrumentality of water alone. This preparation may be used in diarrhœa with acidity, in vomiting, in affections of the urinary organs requiring antacid treatment, and for all other therapeutical purposes to which lime is applied. The dose equivalent to a fluidounce of lime-water is about a fluidrachm.* W

* *Syrup of Lime. Saccharate of Lime.* Under the latter name a preparation has been introduced into notice, made by saturating pure syrup with lime, and filtering. The sugar

LIQUOR FERRI CITRATIS. *U. S.* *Solution of Citrate of Iron.*

"Take of Citric Acid, in coarse powder, *five troyounces and three hundred and sixty grains;* Solution of Tersulphate of Iron *a pint;* Water of Ammonia, Distilled Water, each, *a sufficient quantity.* Dilute the Solution of Tersulphate of Iron with two pints of Distilled Water, add a slight excess of Water of Ammonia, with constant stirring, transfer the precipitate formed to a muslin strainer, and wash it with water until the washings are nearly tasteless. When the precipitate is drained, put half of it in a porcelain capsule on a water-bath, heated to 150°, add the Citric Acid, and stir the mixture until the precipitate is nearly dissolved. Then add so much of the reserved precipitate as may be necessary fully to saturate the Acid. Lastly, filter the liquid, and evaporate it, at a temperature not exceeding 150°, until it is reduced to the measure of a pint." *U. S.*

In this process, the hydrated sesquioxide of iron is first obtained by treating solution of the tersulphate with ammonia, and is then combined, with the aid of heat, with the citric acid, thus forming a solution of the citrate of the sesquioxide of iron, consisting of one eq. of acid and one of sesquioxide. It might appear, from the phraseology of the process, that, in the direction to add the citric acid to the precipitated sesquioxide, the addition of water to hold the resulting citrate in solution had been omitted; but the fact is, that the precipitate, even after draining, retains mechanically quite sufficient water for the purpose, so much, indeed, that evaporation is necessary at the end of the process to reduce the bulk to the required standard. The temperature is limited to 150°, because, though a moderate heat promotes the solution, a high degree of it diminishes the solubility of the oxide, and thus interferes with the process.

The solution has a deep reddish-brown colour, and a slight not unpleasant chalybeate taste. It keeps for a long time without change, and answers admirably well for preparing solid citrate of iron, and the chalybeate salts containing it, and for introducing it into extemporaneous mixtures. Each fluidounce of it contains half a troyounce of citrate of iron. It may be given, for the general purposes of the ferruginous preparations, in the dose of ten minims, equivalent to five grains of the salt, several times a day.

LIQUOR FERRI NITRATIS. *U. S.* Liquor Ferri Pernitratis. *Br.* *Solution of Nitrate of Iron. Solution of Pernitrate of Iron. Solution of Ternitrate of Sesquioxide of Iron.*

"Take of Iron, in the form of wire, and cut in pieces, *two troyounces and a half;* Nitric Acid [sp. gr. 1·42] *five troyounces;* Distilled Water *a sufficient quantity.* Mix the Iron with twelve fluidounces of Distilled Water in a wide-mouthed bottle, and add to the mixture, in small portions at a time, with frequent agitation, three troyounces of the Nitric Acid, previously mixed with six fluidounces of Distilled Water, moderating the reaction by setting the vessel in cold water, in order to prevent the occurrence of red fumes. When the effervescence has nearly ceased, agitate the solution with the undissolved Iron until a portion of the liquid, on being filtered, exhibits a pale-green colour. Then filter the liquid, and, having

forms a soluble compound with the lime, large quantities of which are dissolved by the syrup. The syrup remains perfectly transparent, and is in no degree disturbed by dilution with water. It has a decidedly alkaline and even caustic taste, and should always be largely diluted when administered. It was first prepared by M. Beral; and its practical use was originally suggested by Dr. Capitaine, of Paris. Trousseau has employed it in the chronic diarrhœa of infants, and recommends it as an addition, in very small proportion, to the milk employed as a diet for children liable to this complaint. For this purpose he adds about eight grains of the syrup to the quart of milk. He gives the saturated syrup of lime to a child in the quantity of fifteen or thirty grains in the course of the day; to an adult, in five times the quantity. (*Trait. de Thérap.*, 4e ed., i. 317 and 321.)—*Note to the tenth edition.*

poured it into a capacious porcelain capsule, heat it to the temperature of 130°, and add the remainder of the Nitric Acid. When the effervescence has ceased, continue the heat until no more gas escapes, and then add sufficient Distilled Water to bring the liquid to the measure of thirty-six fluidounces." *U. S.*

"Take of fine Iron Wire, free from rust, *one ounce* [avoirdupois]; Nitric Acid [sp. gr. 1·5] *three fluidounces* [Imperial measure]; Distilled Water *a sufficiency*. Dilute the Nitric Acid with sixteen [fluid]ounces of the Water, introduce the Iron Wire into the mixture, and leave them in contact until the metal is dissolved, taking care to moderate the action, should it become too violent, by the addition of a little more Distilled Water. Filter the solution, and add to it as much Distilled Water as will make its bulk one pint and a half [Imp. meas.]. The specific gravity is 1·107." *Br.*

The above U. S. formula has been substituted for the one adopted in the second edition of the Pharmacopœia, published in Dec. 1855, which upon trial was found by Prof. Procter to have defects, which, it is believed, have been corrected in the present. In the existing formula, nitric acid (sp. gr. 1·42), diluted, is gradually added to an *excess* of iron, mixed with water, so as to ensure the production of the mononitrate of protoxide of iron, which is filtered from the excess of iron. To this is added a quantity of nitric acid, equal to two-thirds of that originally directed, which converts the mononitrate of the protoxide into the ternitrate of the sesquioxide, attended with a violent effervescence of red hyponitric acid vapours. The preparation is finished by giving it a determinate bulk by the addition of water. In this process, the two portions of nitric acid used are correctly adjusted to produce the intended result. Thus, six eqs. of mononitrate, containing six eqs. of nitric acid, require exactly four additional eqs. of acid to effect the conversion; one eq. of the additional acid being expended in converting the six eqs. of protoxide into three eqs. of sesquioxide, and the three remaining eqs. in completing three eqs. of ternitrate.*

The peculiarity of the above process is the addition of the nitric acid in two portions at different times; the first portion not larger than is necessary to form the nitrate of the protoxide, and the second sufficient to convert this into the ternitrate of the sesquioxide. The object gained by this procedure seems to be to obviate the tendency which nitric acid has to sesquioxidize a larger portion

* Prof. Procter has proposed the following formula for a *syrup of the nitrate of protoxide of iron*, a preparation considerably used, in Philadelphia, as an astringent in chronic diarrhœa. Take of Iron Wire, in pieces (card teeth), *two ounces;* Nitric Acid (sp. gr. 1·42) *three fluidounces;* Water *thirteen fluidounces;* Sugar, in powder, *two pounds*. Put the iron in a wide-mouthed bottle, kept cool by standing in cold water, and pour upon it three fluidounces of water. Then mix the acid with ten fluidounces of water, and add the mixture in portions of half a fluidounce to the iron, agitating frequently until the acid is saturated, using litmus paper. When the saturation is complete, filter the solution into a bottle containing the sugar, and marked to contain thirty fluidounces. If the whole does not measure that bulk, pass water through the filter to make up the deficiency. When all the sugar is dissolved, strain if necessary, and introduce the syrup into suitable vials, and seal them. This syrup is thick, permanent, of a light-greenish colour, perfectly transparent, neutral, and yields a greenish precipitate with ammonia. (*Am. Journ. of Pharm.*, Oct. 1851, p. 314.) Mr. W. W. D. Livermore has given a formula for a similar syrup. (*Ibid.*, p. 315.) A third formula has been proposed by Mr. Thomas Lancaster, of this city, in which the nitrate of protoxide of iron is obtained by double decomposition between nitrate of lime and sulphate of protoxide of iron. (*Ibid.*, Sept. 1854, p. 400.) These syrups should not contain an excess of acid; for if they do, they are apt to deposit, after keeping, white granular masses of grape sugar, as observed by Mr. W. Tozier, of Kingstown, Ireland, in consequence of the action of the acid upon the cane sugar. According to Mr. Joseph Laidley, of Richmond, Va., the so-called syrup of the nitrate of sesquioxide of iron is an unscientific preparation, containing protoxide if an excess of acid is avoided, and liable to let fall a precipitate of oxalate of iron when the acid is in excess. Hence Mr. Laidley believes that the only nitrate, proper to be formed into a syrup, is the nitrate of the protoxide, where alone the protective influence of sugar is required. (*Ibid.*, March, 1853, p. 97.)—*Note to the tenth and eleventh editions.*

of iron than can be neutralized by what remains of the acid, unless this be employed in such a proportion as to endanger an excess in the resulting solution. By this excess of sesquioxide, a subsalt is formed, which is not readily held in solution with the neutral sesquinitrate, and is therefore apt to be slowly deposited from the officinal preparation, unless care is taken to prevent its production.

The U. S. solution of nitrate of iron has a sp. gr. between 1·060 and 1·070, a pale-amber colour, and a strong astringent acid taste. It contains no protoxide of iron, and does not give a blue precipitate with ferridcyanide of potassium. A fluidounce of it, on the addition of an excess of ammonia, yields a reddish-brown precipitate, which, when washed, dried, and ignited, weighs between eight and ten grains. (*U. S.*) The British preparation is of a reddish-brown colour, of the sp. gr. 1·107, and gives no precipitate with ferridcyanide of potassium. The precipitate obtained from a fluidrachm of it by the addition of an excess of ammonia, when washed, dried, and ignited, weighs 2·6 grains. (*Br.*) It is, therefore, about twice as strong as the U. S. solution.

Ternitrate of sesquioxide of iron, as described by Mr. J. M. Ordway, of Massachusetts, is in the form of oblique rhombic prisms, which are either colourless, or of a delicate lavender colour. It is somewhat deliquescent, very soluble in water, and sparingly soluble in nitric acid. It consists of three eqs. of nitric acid, one of sesquioxide of iron, and eighteen of water. (*Silliman's Journ.*, Jan. 1850.) S. Hausmann found only twelve eqs. of water. (*Chem. Gaz.*, June 1, 1854.)

Medical Properties. This solution was introduced to the notice of the profession by Mr. William Kerr, in 1832. Its virtues are those of a tonic and astringent. Dr. R. J. Graves, of Dublin, praises it as a remedy in chronic diarrhœa, especially when occurring in delicate and nervous women, in which there is no thirst, redness of tongue, tenderness of the abdomen on pressure, or other indication of inflammation. Mr. Kerr attributed to it the property of diminishing the irritability of the intestinal mucous membrane. It is particularly applicable to the treatment of mucous diarrhœa, attended with pain, but not to cases in which ulcerations of the intestines exist. Dr. T. C. Adams, of Michigan, also reports favourably of this remedy in chronic diarrhœa, considering it, like Mr. Kerr, to act as a sedative as well as astringent. He employed it, likewise with good effect, in menorrhagia, and both internally and by injection in leucorrhœa, when occurring in pale, exsanguine, and feeble subjects. The dose, according to Dr. Graves, is seven or eight drops, gradually increased to fifteen, sufficiently diluted, given in the course of the day. Dr. Adams gave it in doses of ten drops, two, three, or four times a day, and sometimes increased it to twenty-five drops. Dr. Garrod and Mr. Squire, the two most prominent expounders of the British Pharmacopœia, state the dose of the British preparation, though twice as strong in iron as our own, at from thirty minims to a fluidrachm. Considering that a fluidrachm of the British solution contains 7·865 grains of the salt, this appears to us a very large dose; and the doses recommended by Drs. Graves and Adams would probably be safer. As an injection Dr. Adams employed it sufficiently diluted to cause only a slight heat and smarting in the vagina. B.

LIQUOR FERRI PERCHLORIDI. *Br.* *Solution of Perchloride of Iron.*

"Take of Iron Wire *two ounces* [avoirdupois]; Hydrochloric Acid *ten fluidounces;* Nitric Acid *six fluidrachms;* Distilled Water *seven fluidounces.* Dilute the Hydrochloric Acid with five [fluid]ounces of the Water, and pour the mixture on the Iron Wire in successive portions, applying a gentle heat when the action becomes feeble, so that the whole of the metal may be dissolved. To the Nitric Acid add the two remaining ounces of Water, and, having poured the mixture into the solution of iron, evaporate the whole until the bulk is reduced to ten fluidounces." *Br.*

By the reaction between the muriatic acid and iron a chloride of that metal

is produced, which by the subsequent agency of the nitric acid is converted into the sesquichloride, or, as denominated in the Br. Pharmacopœia, the perchloride, which is held in solution by the water.

It was intended that the conversion of the protochloride into sesquichloride should be complete; and hence the solution is described as having an orange-brown colour, and as not being precipitated by ferridcyanide of potassium, which throws down a blue precipitate with the protochloride. But it is stated by Mr. Squire that, if made in accordance with the officinal directions, the solution is almost black in consequence of the presence of protochloride, and besides contains free nitric acid; the whole of that directed in the formula not being decomposed. According to the Pharmacopœia, it mixes with water and alcohol in all proportions; and it is by the addition of alcohol to it that the British tincture of the chloride is formed; whereas, in reality, if mixed with alcohol in the proportion ordered for the tincture, it yields a considerable deposit. The error of the Pharmacopœia consists in an insufficient concentration, after the addition of the nitric acid, so that the nitric acid has not been completely decomposed, and failed of course to change the protochloride completely into the sesquichloride. But, should the evaporation be continued, a large quantity of basic chloride is thrown down because the proportion of muriatic acid directed in the formula is insufficient to sesquichloridize the whole of the protochloride. The formula, therefore, requires revision in both these respects. The muriatic acid must be increased to twelve fluidounces, and the evaporation continued to five fluidounces. Then by adding sufficient water to make the measure of the solution ten fluidounces, a preparation will be obtained such as was contemplated, though its sp. gr. will be 1·410, instead of 1·338 as given in the Pharmacopœia. (*Compan. to Br. Pharm.*, p. 100.)

The solution of perchloride of iron, properly made, is of an orange-colour, and a strongly astringent, chalybeate taste. Water and alcohol unite with it in all proportions. When diluted with water, it gives a white precipitate with nitrate of silver, and a blue one with the ferrocyanide of potassium, but not with the ferridcyanide. The Pharmacopœia gives as a test that "a fluidrachm of it diluted with two fluidounces of water gives, upon the addition of an excess of solution of ammonia, a reddish-brown precipitate, which, when well washed and incinerated, weighs 15·62 grains." *Br.* Were this test to be relied on, the solution would be about four times as strong in iron as the U. S. Tincture of the Chloride.*

Medical Uses. This preparation was brought prominently into notice by M. Pravaz, a surgeon of Lyons, who found that a few drops of a strong solution, injected into a blood-vessel, produced coagulation of all the blood in the vessel for the extent of an inch or more. Its use as a styptic was the necessary result

* This solution, when kept, has a disposition to deposit the insoluble oxychloride of iron, and the resulting excess of muriatic acid is apt to render it injuriously irritating. To obviate this disadvantage, M. Burin du Buisson recommends the following mode of preparation. "Saturate as quickly as possible pure and colourless muriatic acid with [gelatinous] hydrated peroxide of iron; evaporate the solution to somewhat less than one-half over a gentle fire; and then continue the evaporation by means of the salt-bath, taking care to remove the aqueous vapours, which would cause the formation of muriatic acid, and a deposition of insoluble oxychloride. When the solution has attained the consistence of thick syrup (in which state it curdles on cooling, without, however, becoming a solid mass), cease evaporating, add an excess of the gelatinous hydrate diluted with a little water, agitate for a quarter of an hour, and afterwards allow the liquor to rest for several hours. Next add distilled water sufficient to bring the solution to the density of 30° Baumé, and allow it to stand for eight days in contact with an excess of the hydrate; after which filter, and again allow it to stand for two weeks." This strength of the solution is required for the cure of varices. For injection into aneurismal tumours, it is sufficient to employ a solution of 20° or even 15°. These degrees of Baumé are equivalent, 30° to 29·70 per cent. of the dry salt, 20° to 17·05 per cent., and 15° to 12·10 per cent. (See *Ferri Chloridum*, U. S., *page* 1·26.)

of this observation. In this capacity it has been used in the cure of varices, and has even been recommended as an injection in ordinary aneurisms. In arresting hemorrhages from cut surfaces or wounded vessels it has proved remarkably successful. It has also been found advantageous as an application to nasal polypi, in ulcers about the nails, and in various cutaneous affections. (See *Chloride of Iron.*) It may be used internally, properly diluted, for the general purposes of the chalybeates, and especially as a substitute for the tincture of the chloride of iron, when the alcohol of that preparation may be objectionable. The dose would be from two to ten minims. In the Br. Pharmacopœia it is used in the preparation of the tincture of the chloride.

Off. Prep. Tinctura Ferri Perchloridi, *Br.* W.

LIQUOR FERRI SUBSULPHATIS. *U. S. Solution of Subsulphate of Iron. Solution of Persulphate of Iron. Monsel's Solution.*

"Take of Sulphate of Iron, in coarse powder, *twelve troyounces;* Sulphuric Acid *a troyounce and thirty grains;* Nitric Acid *a troyounce and three hundred grains;* Distilled Water *a sufficient quantity.* Mix the Acids with half a pint of Distilled Water, in a capacious porcelain capsule, and, having heated the mixture to the boiling point, add the Sulphate of Iron, one-fourth at a time, stirring after each addition until effervescence ceases. Then keep the solution in brisk ebullition until nitrous vapours are no longer perceptible, and the colour assumes a deep ruby tint. Lastly, when the liquid is nearly cold, add sufficient Distilled Water to make it measure twelve fluidounces." *U. S.*

This process is essentially that of Dr. Squibb, published in the *American Journal of Pharmacy* for January, 1860 (p. 33). The object is to obtain in solution *Monsel's persulphate of iron*, improperly so called, as it differs both in composition and properties from the salt of iron properly named persulphate. This consists of one eq. of sesquioxide of iron and three of sulphuric acid (Fe_2O_3, $3SO_3$), and is a neutral salt, while Monsel's persulphate consists of two eqs. of the sesquioxide and five of the acid ($2Fe_2O_3.5SO_3$), and, having one-half of an eq. less than is necessary for saturation, is properly a subsalt, as it is very appropriately designated in the U. S. Pharmacopœia. With this preliminary explanation, the process will be easily understood.

In its preparation the protoxide of iron of the protosulphate is sesquioxidized at the expense of the nitric acid; but the sulphuric acid, mixed with the nitric, is in quantity insufficient to the increased demand by the sesquioxide for neutralization. Thus, for each equivalent of the sesquioxide produced an additional eq. of acid would be necessary to constitute the neutral tersulphate of the sesquioxide, while the quantity added is only the half of one equivalent. The sesquioxide is therefore but partially saturated and a subsalt results, having the constitution above mentioned.

The solution of subsulphate of iron is of a syrupy consistence, a ruby-red colour, inodorous, of an extremely astringent but not acrid taste, without causticity, and of the sp. gr. 1·552. It mixes with water and alcohol in all proportions without decomposition. With ammonia it yields a copious reddish-brown precipitate of sesquioxide of iron. A little sulphuric acid decolorizes the liquid in a considerable degree, and an excess of the same acid converts it into a white, soft, pasty solid, resembling plaster of Paris when it has begun to solidify after mixture with water. This test, according to Dr. Squibb, is quite characteristic. (*Transact. King's Co. Med. Soc.*, in N. Y. *Journ. of Med.*, March, 1860, p. 173.)

By evaporation, upon a glass surface, with a moderate heat, the solution yields the subsulphate of the sesquioxide of iron in the form of thin transparent scales, of a light reddish-brown colour, deliquescent, and readily soluble in water.

Attention was first called to the special styptic virtues of sulphate of peroxide of iron by M. Monsel in 1852; but it was not till a later period that he discovered the peculiar salt which now goes by his name, and the solution of

which is the subject of the present article. It was in 1857 that he published a formula for the salt. (See *Journ. de Pharm.*, Sept. 1857, and Juillet, 1859.) The remedy soon became generally known in Europe; and a paper on the subject was published by Dr. Hutchison in the *New York Journal of Medicine* for January, 1859; but it seems to have come into more general use in this country, through the published experience of Dr. H. H. Toland and others in the *Pacific Medical and Surgical Journal* of California.

In consequence of its deficiency of sulphuric acid, this salt is less irritant than the tersulphate of the sesquioxide, while it has at least equal if not greater astringency. It is therefore very efficacious as a styptic, and peculiarly adapted, through the power of coagulating the blood, to cases of hemorrhage from incised wounds, or surfaces in which it is specially desirable to avoid irritation. It is said also to have been found peculiarly efficacious in chancre. The solution may be applied by means of a small sponge or pencil of spun-glass to the bleeding surface or vessel. It has also been used internally; and there is little doubt that it would prove efficacious as a styptic in hemorrhage from the stomach and bowels, and by injection into the rectum in bleeding from that part. It may be given in a dose of from five to fifteen grains. W.

LIQUOR FERRI TERSULPHATIS. *U. S. Solution of Tersulphate of Iron. Solution of Persulphate of Iron. Br. Appendix.*

"Take of Sulphate of Iron, in coarse powder, *twelve troyounces;* Sulphuric Acid *two troyounces and sixty grains;* Nitric Acid *a troyounce and three hundred and sixty grains;* Water *a sufficient quantity.* Mix the Acids with half a pint of Water in a capacious porcelain capsule, and, having heated the mixture to the boiling point, add the Sulphate of Iron, one-fourth at a time, stirring after each addition until effervescence ceases. Then continue the heat until the solution acquires a reddish-brown colour, and is free from nitrous odour. Lastly, when the liquid is nearly cold, add sufficient Water to make it measure a pint and a half." *U. S.*

This solution is placed in the Appendix of the *British Pharmacopœia*, under the name of *Solution of Persulphate of Iron*, among the substances used in preparing medicines, with the following directions for making it.

"Take of Sulphate of Iron *eight ounces* [avoirdupois]; Sulphuric Acid *six fluidrachms;* Nitric Acid *four fluidrachms;* Distilled Water *twelve fluidounces*, or *a sufficiency.* Add the Sulphuric Acid to ten [fluid]ounces of the Water, and dissolve the Sulphate of Iron in the mixture, with the aid of heat. Mix the Nitric Acid with the remaining two [fluid]ounces of Water, and add the dilute acid to the solution of Sulphate of Iron. Concentrate the whole by boiling, until, upon the sudden disengagement of ruddy vapours, the liquid ceases to be black and acquires a red colour. A drop of the solution is now to be tested with ferridcyanide of potassium, and if a blue precipitate forms, a few additional drops of Nitric Acid should be added, and the boiling renewed, in order that the whole of the protosulphate may be converted into persulphate of iron. When the solution is cold, make the quantity eleven fluidounces by the addition, if necessary, of Distilled Water." *Br.*

The sulphate of iron used in these formulas is a sulphate of the protoxide of iron. The nitric acid in the process gives up enough of its oxygen to convert the protoxide entirely into sesquioxide, and the effervescence is owing to the escape of nitric oxide becoming red hyponitric acid by contact with the air. The conversion of protoxide into sesquioxide is incomplete until the effervescence ceases, and the colour, from black, as it was at first, has become reddish-brown. Indeed, in order to sesquioxidize the whole of the protoxide of the sulphate, it is necessary to continue the heat until nitrous odour ceases to be evolved; and thus, moreover, the entire absence of nitric or nitrous acid from the solution is ensured. But in consequence of the higher oxidation of the iron the sulphuric acid

of the sulphate is insufficient to saturate it, and just in proportion to the additional oxygen. Enough sulphuric acid, therefore, is added to meet this demand, that is, in such proportion as to give an eq. of the acid for each additional eq. of oxygen in the oxide. The process is completed by adding enough water to make a definite measure. The U. S. and British formulas are the same in principle; but in the latter, the additional precaution is taken, in order to ensure the complete change of protoxide into sesquioxide, of testing the liquid with ferridcyanide of potassium, which will produce a blue precipitate so long as any of the protoxide remains.

This solution, prepared according to the U. S. formula, is a perfectly clear and mobile liquid, in no degree viscid, of a reddish-brown colour, almost inodorous, of a sour, extremely astringent and somewhat acrid taste, and miscible in all proportions, without decomposition, with water and alcohol. The sp. gr. of the U. S. solution is 1·320; and a *fluidounce* of it yields, on the addition of ammonia in excess, a bulky precipitate, of a reddish-brown colour, and without blackish tinge, which, when washed, dried, and ignited, weighs 69 grains. The solution, diluted with water, gives a white precipitate with chloride of barium, showing that it contains a sulphate, and a blue precipitate with ferrocyanide of potassium, but none with the ferridcyanide, showing that the sulphate is that of sesquioxide of iron. It keeps well; and we have seen a specimen three or four years old, which retained all its properties unchanged, and had deposited nothing. The *British* solution is considerably stronger than ours, having the sp. gr. 1·441, and yielding from a *fluidrachm*, on precipitation by ammonia, a precipitate, which, when washed and incinerated, weighs 11·44 grains. It is described in the Br. Pharmacopœia as viscid, and of a dark-red colour. Prof. Procter has found that a preparation containing 120 grains of sesquioxide to the fluidounce is apt to deposit the anhydrous sulphate on standing.

This solution, though possessed of astringent properties rendering it useful as a styptic, is inferior remedially to that of the subsulphate of iron, which is less irritant, and certainly not less efficacious. The chief use of it is in making other ferruginous preparations, in which the sesquioxide of iron is wanted; and it should always be kept on hand, if for nothing else, for the quick preparation of the hydrated sesquioxide of iron, to be used as an antidote in cases of arsenical poisoning.

LIQUOR GUTTA-PERCHÆ. *U. S. Solution of Gutta-percha.*

"Take of Gutta-percha, in thin slices, *a troyounce and a half;* Purified Chloroform *seventeen troyounces;* Carbonate of Lead, in fine powder, *two troyounces.* To twelve troyounces of the Chloroform, contained in a bottle, add the Gutta-percha, and shake occasionally until it is dissolved. Then add the Carbonate of Lead, previously mixed with the remainder of the Chloroform, and, having several times shaken the whole together, at intervals of half an hour, set the mixture aside, and let it stand for ten days, or until the insoluble matter has subsided, and the solution become limpid, and either colourless or of a pale-straw colour. Lastly, decant the liquid, and keep it in a well-stopped bottle." *U. S.*

Difficulty is often experienced in obtaining a clear solution of gutta-percha in chloroform of the proper consistence for use, in consequence of its viscidity, and the strong affinity with which it holds on to the colouring matter. It cannot be clarified by filtration; and the carbonate of lead is therefore resorted to, which unites with the colouring matter, and, in consequence of its weight, gradually subsides, carrying undissolved substances along with it, and leaving a clear and

colourless or nearly colourless solution behind. The use of carbonate of lead for the purpose was first suggested by Mr. Wm. Hodgson, jun., of Philadelphia. Something in the success of the process appears to depend on the quality of the gutta-percha used. Should the operator be unable to procure a clear solution by acting in precise accordance with the formula, he would be justifiable in adding more chloroform, filtering if necessary, and evaporating by a very moderate heat to the due consistence. When the preparation becomes too viscid in consequence of the spontaneous evaporation of the menstruum on exposure, we have always found that the addition of a little chloroform, with agitation, restores it without difficulty to the due condition. The ordinary commercial chloroform may be used in the process, as the preparation is exclusively for external use. It should be kept in small glass vials, with accurately fitting glass stoppers, and not containing more than may be wanted at once, say a fluidounce.

We have nothing, on the whole, so convenient and effective as this preparation, as a protective to the surface, in slight cases of superficial inflammation and abrasion. By the rapidity with which the chloroform evaporates, a thin elastic nearly colourless film is left after its application, sufficient to prevent injurious influence from the air, wholly without irritating properties, not shrinking inconveniently, and, in consequence of its softness, not mechanically disturbing the part, as sometimes happens with collodion. A little of it applied by the end of the finger, or by means of a small brush, or a glass rod, over eruptive affections, abrasions or slight excoriations, inflammation from friction, chaps on the lips or hand, and slight superficial wounds that have ceased bleeding, will often enable the parts beneath to heal almost immediately, while, if unprotected, they might go on for an indefinite period, giving annoyance, and often increasing. Surfaces, yet sound, that are liable to irritation and abrasion from contact, pressure, friction, and the application of acrid substances, may often be protected by a coating of this material. The agreeable odour of chloroform is another recommendation over other preparations, of a similar character, made with ether or benzole. We have so often experienced its advantages that we wish to press it upon the attention of the profession, which it has not yet received to the degree that it merits. One cause of this, perhaps, is the difficulty of obtaining it in the shops, a large proportion of which, either from the difficulties in its preparation, or want of demand, are insufficiently supplied. W.

LIQUOR HYDRARGYRI NITRATIS. *U. S.* Liquor Hydrargyri Nitratis Acidus. *Br. Solution of Nitrate of Mercury. Acid Solution of Nitrate of Mercury.*

"Take of Mercury *three troyounces;* Nitric Acid *five troyounces;* Distilled Water *six fluidrachms.* Dissolve the Mercury, with the aid of a gentle heat, in the Acid previously mixed with the Distilled Water. When reddish vapours cease to arise, evaporate the liquid to seven troyounces and a half, and keep it in a well-stopped bottle." *U. S.*

"Take of Mercury *four ounces* [avoirdupois]; Nitric Acid [sp. gr. 1·5] *three fluidounces and a quarter* [Imperial measure]; Distilled Water *three fluidounces.* Mix the Nitric Acid with the Water in a flask; and dissolve the Mercury in the mixture without the application of heat. Boil gently for fifteen minutes, cool, and preserve the solution in a stoppered bottle." *Br.*

In the process for making this new officinal of the U. S. Pharmacopœia, mercury is dissolved, with the assistance of heat, in an excess of nitric acid, and there is formed an acid binitrate of deutoxide of mercury, which is brought to a determinate bulk by evaporation. The nitric acid taken weighs five ounces. This proportion is sufficient not only to deutoxidize the mercury and generate a bisalt, but to furnish a large excess of acid. The solution is a dense, transparent, nearly colourless liquid, of a strongly acid taste, of the sp. gr. 2·165 as

prepared by the U. S. process, and 2·246 by the British. Its distinguishing properties, as given in the U. S. and Br. Pharmacopœias, are that it is not precipitated by distilled water; gives when diluted a dull yellow precipitate with potassa and a bright red one soluble in an excess of the precipitant with iodide of potassium; does not produce a precipitate when dropped into muriatic acid diluted with twice its bulk of water; when dropped on a bright surface of copper instantly occasions a mercurial coating; and, finally, causes a crystal of sulphate of iron dropped into it, as well as the liquid around the salt, to assume a dark colour. These tests show that the salt contained in it is a nitrate and not a sulphate, and that its base is deutoxide of mercury, without the presence of any protoxide of that metal. The rather loose direction, at the close of the British process, to boil for fifteen minutes, cannot but lead to somewhat uncertain results, unless care is taken by the operator to bring the sp. gr. of the solution to the point indicated in the description of the solution, given in another part of the Pharmacopœia.

Binitrate of deutoxide of mercury (the salt present in this preparation) is uncrystallizable, unless when exposed in a freezing mixture to a temperature of 5°, when it crystallizes with the formula $HgO_2,2NO_5+16HO$. (*H. S. Ditten.*) According to the new view of the equivalent of mercury, adopted in the Br. Pharmacopœia, the salt is a nitrate of protoxide of mercury, and is represented by the formula, independently of water of crystallization, HgO,NO_5.

Medical Properties. This preparation is frequently used in Europe, and has been employed to some extent in this country, as a caustic application to malignant ulcerations and cancerous affections. It has been used by Biett in lupus, by Bennett and others in ulceration of the neck of the uterus, and by Recamier in cancer. It is applied to the diseased surface by a camel's hair brush, or preferably by a brush made of spun-glass. The parts touched immediately become white, the surrounding parts inflame, and in a few days a yellow scab is formed, which gradually falls off. Sometimes the application produces salivation. When it is desirable to avoid this result, the cauterized part should be washed with water immediately after the application of the caustic.

Acid nitrate of mercury is extensively used by Mr. Startin in the Hospital for Cutaneous Diseases, London.* He has employed it with advantage in acne, boils, carbuncle, lupus, sloughing ulcers, and other external affections. In acne, a very minute drop of the solution is placed, by means of a finely pointed glass brush, on the top of each indolent tubercle. The application, if carefully made, leaves no scar. In treating boils, a full-sized drop is applied to the apex of the furuncle. (*Med. Times and Gaz.*, Jan. 1855, p. 9.) B.

LIQUOR IODINII COMPOSITUS. *U. S. Compound Solution of Iodine.*

"Take of Iodine *three hundred and sixty grains;* Iodide of Potassium *a troyounce and a half;* Distilled Water *a pint.* Dissolve the Iodine and Iodide of Potassium in the Distilled Water." *U. S.*

In this solution iodine is dissolved in water with the assistance of iodide of potassium. Iodine dissolves sparingly in water, but freely in a solution of that salt. In using iodide of potassium to render iodine more soluble in water, the iodide is generally taken in a quantity twice the weight of the iodine; and this is the proportion adopted in the U. S. formula. The preparation is a *concentrated* solution of iodine with iodide of potassium, and is intended to facilitate the administration of the combination in drops. A solution of the same kind, though weaker, was directed in the Edinburgh Pharmacopœia, but has been omitted in the British. The medicinal properties of the solution depend mainly

* The acid nitrate, used by Mr. Startin, does not correspond, in the proportions employed, with the British preparation. It is made by dissolving two ounces of mercury in four ounces of nitric acid (sp. gr. 1·5).

on the free iodine contained in it, by which the dose must be regulated, and not by the iodide of potassium. According to Mr. Lloyd, of St. Bartholomew's Hospital, London, it acts differently from iodide of potassium, which, when given alone, does not produce the same effects. In a case of constitutional syphilis under his care, the compound solution of iodine effected a rapid cure, after the iodide of potassium had been taken in large doses, for several months, without benefit. The dose is six drops, containing about a quarter of a grain of iodine, three times a day, given in four tablespoonfuls of sweetened water, and gradually increased. The dilution should always be large, in order to favour the absorption of the medicine, and to avoid any irritation of the stomach. For children the dose to begin with is two drops. B.

LIQUOR MAGNESIÆ CITRATIS. *U. S. Solution of Citrate of Magnesia.*

"Take of Magnesia *one hundred and twenty grains;* Citric Acid *four hundred and fifty grains;* Syrup of Citric Acid *two fluidounces;* Bicarbonate of Potassa *forty grains;* Water *a sufficient quantity.* Dissolve the Citric Acid in four fluidounces of Water, and, having added the Magnesia, stir until it is dissolved. Filter the solution into a strong twelve-ounce bottle containing the Syrup of Citric Acid. Then add the Bicarbonate of Potassa, and sufficient Water to nearly fill the bottle, which must be closed with a cork secured with twine. Lastly, shake the mixture occasionally until the Bicarbonate is dissolved." *U. S.*

This is a revised formula for solution of citrate of magnesia, which first appeared in the second edition of the U. S. Pharmacopœia of 1850. The original formula was soon found to have several defects. It called for the use of carbonate of magnesia, which often contains gritty impurities. Four-fifths of the carbonate was dissolved in the citric acid, and the solution filtered into a bottle containing the syrup of citric acid; and then the reserved fifth, mixed with water, was added to the acid citrate, and the bottle tightly corked. The addition of the reserved carbonate was intended to impregnate the preparation with carbonic acid by its solution in the excess of citric acid. To effect the solution of this reserved carbonate required at least half an hour. But the chief objection to the formula, as originally framed, was that the citrate of magnesia, when the solution was kept for some days, underwent a molecular change, resulting in the formation of a white granular precipitate, which rendered the solution unfit for medical use. This precipitate was found by Prof. Procter to consist of one eq. of citric acid, three of magnesia, and fourteen of water. In the revised formula, now adopted, magnesia, which is generally purer than the carbonate, is substituted for it; and the impregnation of the solution with carbonic acid is effected by adding, just before the closing of the bottle, a small quantity of bicarbonate of potassa in *crystals*, which dissolve immediately, instead of consuming half an hour. Solution of citrate of magnesia, made by this formula, is not liable to the objection of letting fall a granular precipitate, and may be prepared in a short time. The use of bicarbonate of potassa, it is true, introduces citrate of potassa, but in too small a proportion to be of any consequence.

Properties, &c. This officinal solution is founded on a preparation proposed by M. Rogé Delabarre, and improved by M. Rabourdin, of Paris. It is an aqueous solution of citrate of magnesia, containing an excess of citric acid, impregnated with carbonic acid, and sweetened with syrup. When properly prepared, it is a clear liquid, having an agreeable taste like that of lemonade. Overlooking the excess of acid which it contains, the salt present is that tribasic citrate, in which the three eqs. of basic water in the crystallized acid are replaced by three eqs. of magnesia. Accordingly it consists of one eq. of citric acid and three of magnesia. In the revised formula, this salt does not precipitate by keeping, as in the superseded one, probably because the solution contains a greater excess of acid.

Dorvault makes a solid citrate of magnesia which is perfectly and readily soluble, by melting on a sand-bath 100 parts of crystallized citric acid in its water of crystallization, and thoroughly incorporating with it 29 parts of calcined magnesia. A pasty mixture is formed, which soon hardens, and may be pulverized for use. Citrate of magnesia, thus prepared, is soluble in twice its weight of water. When in saturated solution it soon precipitates as a nearly insoluble hydrate; but with eight or ten times its weight of water, it forms a permanent solution. See the report on the solid citrate, made by E. Parrish and A. Smith to the Philadelphia College of Pharmacy (*Am. Journ. of Pharm.*, April, 1852, p. 113). See also M. E. Robiquet's paper on lemonades of citrate of magnesia (*Journ. de Pharm.*, April, 1852, p. 295), and his formula for preparing a soluble citrate of magnesia (*Am. Journ. of Pharmacy* for July, 1855). M. Simonin finds that an insoluble citrate of magnesia may be restored to solubility in boiling water, by being thoroughly rubbed up with water so as to form a paste. The necessary trituration is abridged, if a little citric acid be added. (*Ann. de Thérap.*, 1857, p. 124.) Mr. Charles Ellis, of this city, prepares a soluble citrate of magnesia with sugar, citric acid, bicarbonate of soda, and oil of lemons, in the form of a powder, which effervesces when mixed with water. For the details of the formula, the reader is referred to his paper in the *Am. Journ. of Pharmacy* for July, 1854.*

Medical Properties. This solution is a cooling cathartic, and operates mildly. It has come into extensive use in the United States, on account of the facility with which it may be taken, and its acceptability to the stomach. The dose as a full purge is the whole quantity directed in the formula, or twelve fluidounces; as a laxative, half that quantity or less. B.

LIQUOR MORPHIÆ HYDROCHLORATIS. *Br.* LIQUOR MORPHIÆ MURIATIS. *Dub. Solution of Hydrochlorate of Morphia. Solution of Muriate of Morphia.*

"Take of Hydrochlorate of Morphia *four grains;* Dilute Hydrochloric Acid *eight minims;* Rectified Spirit *two fluidrachms;* Distilled Water *six fluidrachms.* Mix the Hydrochloric Acid, the Spirit, and the Water, and dissolve the Hydrochlorate of Morphia in the mixture." *Br.*

The use of the alcohol is to prevent spontaneous decomposition, that of the

* *Solid Citrate of Magnesia.* This salt as heretofore prepared, though soluble at first, is apt to become more or less insoluble, when kept, in consequence of molecular change. The following process, by M. de Letter, of Brussels, yields a salt which is said to retain its solubility indefinitely. "Take of Citric Acid 20 parts, and of Carbonate of Magnesia 12 parts. Powder the acid finely, and mix it intimately with the carbonate, also in fine powder. Allow the mixture to stand, at the ordinary temperature, for four or five days, or until it ceases to manifest reaction when a little is thrown into water. During this time the powder slowly swells up, and gradually assumes the appearance of a spongy mass. Dry this at 86° F., pulverize it, and keep the powder in closely stopped vials." According to M. de Letter, water, in a certain quantity, favours the formation of an insoluble hydrate; and hence the success of his process, in which no other water is present than that which is solidified in the dry materials. (See *Am. Journ. of Pharm.*, July, 1863, p. 312.)

M. Hager has been unable to prepare a soluble salt by the process of M. de Letter. He considers citrate of magnesia as presenting itself in three forms: 1. *crystallizable*, soluble in from 80 to 90 parts of water, with the formula $3MgO,Ci+14HO$; 2. *amorphous*, soluble in two parts of water; and 3. *metamorphous*, soluble in 8 or 10 parts of water, with a strong tendency to crystallize. It is the crystalline variety, presenting the form of microscopic needles, that occasions the difficulty; and its production should be avoided. M. Hager proceeds in the following manner. Rub 40 parts of citric acid and 25 of carbonate of magnesia, both in powder, with sufficient alcohol of ·833 to make a thick mixture; and, having allowed this to stand for several days, at a medium temperature, dry it at a heat of 113° F. The product is the amorphous salt, soluble in 2·5 parts of water, in half an hour at 60°, immediately at 86°. Its solution, whether made with hot or cold water, retains its clearness after long standing. The salt is neutral, and contains about 13 eqs. of water. To succeed certainly it is necessary that the carbonate of magnesia be free from dust and impurities. (*Ibid.*, Jan. 1864, p. 19.)—*Note to the twelfth edition.*

acid probably to assist in the solution of the salt. It is unfortunate that, in the solutions of the salts of morphia, the same degree of strength should not have been directed by the U. S. and Br. Pharmacopœias. As they now are, the medical practitioner and apothecary must be on their guard to avoid serious results The strength of this solution is four times that of our officinal solution of sulphate of morphia, one fluidounce of the former containing four grains, of the latter only one grain of their respective salts. The full dose of the British solution for an adult is from fifteen to thirty minims or drops, containing from an eighth to a quarter of a grain of the hydrochlorate, and about equivalent to as many drops of laudanum. W.

LIQUOR MORPHIÆ SULPHATIS. *U. S. Solution of Sulphate of Morphia.*

"Take of Sulphate of Morphia *eight grains;* Distilled Water *half a pint.* Dissolve the Sulphate of Morphia in the Distilled Water." *U. S.*

Sulphate of morphia, as found in the shops, is not always entirely soluble in water. This sometimes, perhaps, arises from adulterations; but more frequently, in all probability, from the mode of making the sulphate. As this salt was formerly prepared, the quantity of water employed for the suspension of the morphia was sometimes insufficient to hold the resulting sulphate in solution; and the consequence was that, upon the addition of sulphuric acid, the crystallization of the sulphate took place before the whole of the morphia was saturated by the acid. A portion of uncombined morphia was therefore necessarily mixed with the salt. Under such circumstances, the addition of a little sulphuric acid usually remedied the defect, and rendered the whole soluble. Pure sulphate of morphia is readily and entirely soluble in water.

This solution is very convenient, by enabling the physician to prescribe a minute dose, which, in consequence of the great energy of the preparations of morphia, is often necessary. It has the advantage that it may be kept for a very considerable length of time unchanged. The full dose for an adult is from one to two fluidrachms, containing from an eighth to a quarter of a grain of the sulphate.

Unfortunately, in some parts of the Union, the formula of Magendie for this solution, containing 16 grains in a fluidounce, is habitually employed under the name of solution of sulphate of morphia. This is the proper name of the officinal solution, which is much weaker; and the most dangerous results may ensue from the confusion. Magendie's solution should never be prescribed or sold, unless under some special designation. W.

LIQUOR PLUMBI SUBACETATIS. *U. S., Br. Solution of Subacetate of Lead.*

"Take of Acetate of Lead *sixteen troyounces;* Oxide of Lead [Litharge], in fine power, *nine troyounces and a half;* Distilled Water *a sufficient quantity.* Boil the Acetate and Oxide with four pints of Distilled Water, in a glass or porcelain vessel, for half an hour, occasionally adding Distilled Water to preserve the measure, and filter through paper. Lastly, keep the liquid in a well-stopped bottle." *U. S.* The sp. gr. of this solution is 1·267.

"Take of Acetate of Lead *five ounces* [avoirdupois]; Litharge, in powder, *three ounces and a half* [avoird.]; Distilled Water *one pint* [Imperial measure], or *a sufficiency.* Boil the Acetate of Lead and the Litharge in the Water for half an hour, constantly stirring; then filter, and, when the liquid is cold, add to it more Distilled Water, until the product measures twenty fluidounces. Keep the clear solution in stoppered bottles." *Br.* The sp. gr. of the solution is 1·260.

Crystallized acetate of lead consists of one equivalent of acetic acid 51, one of protoxide of lead 111·6, and three of water 27 = 189·6. Litharge, as usually found in the shops, is an impure protoxide of lead. When the solution of the

former is boiled with the latter, a large quantity of the protoxide is dissolved, and a subacetate of lead is formed which remains in solution. The precise composition of the subacetate varies with the proportion of acetate of lead and of litharge employed. When the quantity of the latter exceeds that of the former by one-half or more, the acetic acid of the acetate unites, according to the highest chemical authorities, with two additional equivalents of protoxide, forming a trisacetate; when the two substances are mixed in proportions corresponding with their equivalent numbers, that is, in the proportion of 189·6 of salt to 111·6 of oxide, or 10 to 6 nearly, only one additional equivalent of protoxide unites with the acid, and a diacetate of lead is produced. In the officinal process, the proportions appear to have been arranged in reference to this result. In executing the process, the litharge should be employed in very fine powder, and, according to Thenard, should be previously calcined in order to decompose the carbonate of lead, which it always contains in greater or less proportion, and which is not dissolved by the solution of the acetate.

In former editions of the London and Dublin Pharmacopœias, a different process was directed, consisting in boiling litharge with distilled vinegar, the former being in much larger proportion than necessary to form the neutral acetate. A diacetate was thus produced; but, as the vinegar was of uncertain strength, there was necessarily more or less inequality of strength in the preparation. This process, therefore, has been abandoned. The solution prepared from litharge and distilled vinegar has a pale greenish-straw colour, owing to impurities in the vinegar. Made with common vinegar it is brown.

Properties. The solution of subacetate of lead of the Pharmacopœias is colourless, and of a sweetish, astringent taste. When concentrated by evaporation, it deposits on cooling crystalline plates, which, according to Dr. Barker, are flat, rhomboidal prisms, with dihedral summits. It has an alkaline reaction, tinging the syrup of violets green, and reddening turmeric paper. One of its most striking properties is the extreme facility with which it is decomposed. Carbonic acid throws down a white precipitate of carbonate of lead; and this happens by mere exposure to the air, or by mixture even with distilled water, if this has had an opportunity of absorbing carbonic acid from the atmosphere. It affords precipitates also with the alkalies, alkaline earths, and their carbonates, with sulphuric and muriatic acids free or combined, with hydrosulphuric acid and the hydrosulphates, with the soluble iodides and chlorides, and, according to Thenard, with solutions of all the neutral salts. Solutions of gum, tannin, most vegetable colouring principles, and many animal substances, particularly albumen, produce with it precipitates consisting of the substance added and oxide of lead. It should be kept in well-stopped bottles. It is known to contain a salt of acetic acid by emitting an acetous smell when treated with sulphuric acid; and a salt of lead, by yielding a white precipitate with an alkaline carbonate, a yellow one with iodide of potassium, and a black one with hydrosulphuric acid. It is distinguished from the solution of acetate of lead by being precipitated by gum arabic. Two fluidrachms of the Br. solution require for perfect precipitation twenty-seven measures of the *volumetric solution of oxalic acid*. (*Br.*)

Medical Properties and Uses. This solution is astringent and sedative, but is employed only as an external application. It is highly useful in inflammation arising from sprains, bruises, burns, blisters, &c., to which it is applied by means of linen cloths, which should be removed as fast as they become dry. It always, however, requires to be diluted. From four fluidrachms to a fluidounce, added to a pint of distilled water, forms a solution sufficiently strong in ordinary cases of external inflammation. When applied to the skin denuded of the cuticle, the solution should be still weaker; as constitutional effects might result from the absorption of the lead. Paralysis is said to have been produced by its local action. The solution has the common name of *Goulard's extract*, de-

rived from a surgeon of Montpellier, by whom it was introduced into general notice, though previously employed.

Off. Prep. Ceratum Plumbi Subacetatis, *U. S.;* Liquor Plumbi Subacetatis Dilutus; Unguentum Plumbi Subacetatis, *Br.* W.

LIQUOR PLUMBI SUBACETATIS DILUTUS. *U. S.*, *Br. Diluted Solution of Subacetate of Lead. Lead-water.*

"Take of Solution of Subacetate of Lead *three fluidrachms;* Distilled Water *a pint.* Mix them." *U. S.*

"Take of Solution of Subacetate of Lead *two fluidrachms;* Rectified Spirit *two fluidrachms;* Distilled Water *nineteen fluidounces and a half.* Mix, and filter through paper. Keep the clear solution in a stoppered bottle." *Br.*

This preparation is convenient; as, in consequence of the subsidence of the carbonate of lead usually formed on the dilution of the strong solution, it enables the apothecary to furnish clear lead-water when it is called for. In our comments on the U. S. process of 1850, it was stated that the strength of our officinal preparation, though double what it formerly was, might be still further increased with propriety. In the present edition of the U. S. Pharmacopœia the proportion has been increased from two to three fluidrachms to the pint. The Br. preparation, though stronger than the old one of the London College, is still feeble. The old French Codex directed two drachms of the strong solution to a pound of distilled water, and an ounce of alcohol of 22° Baumé, and thus formed the *vegeto-mineral water* of Goulard. The minute proportion of proof spirit in the British solution can have little effect. The preparation should be as much as possible excluded from the air. W.

LIQUOR POTASSÆ. *U. S.*, *Br. Solution of Potassa.*

"Take of Bicarbonate of Potassa *fifteen troyounces;* Lime *nine troyounces;* Distilled Water *a sufficient quantity.* Dissolve the Bicarbonate in four pints of Distilled Water, and heat the solution until effervescence ceases. Then add Distilled Water to make up the loss by evaporation, and heat the solution to the boiling point. Mix the Lime with four pints of Distilled Water, and, having heated the mixture to the boiling point, add it to the alkaline solution, and boil for ten minutes. Then transfer the whole to a muslin strainer, and, when the liquid portion has passed, add sufficient Distilled Water, through the strainer, to make the strained liquid measure seven pints. Lastly, keep the liquid in well-stopped bottles of green glass. Solution of Potassa, thus prepared, has the sp. gr. 1·065, and contains 5·8 per cent. of hydrate of potassa.

"Solution of Potassa may also be prepared in the following manner.

"Take of Potassa *a troyounce;* Distilled Water *a pint.* Dissolve the Potassa in the Distilled Water, and allow the solution to stand until the sediment subsides. Then pour off the clear liquid, and keep it in a well-stopped bottle of green glass." *U. S.*

"Take of Carbonate of Potash *one pound* [avoirdupois]; Slaked Lime *twelve ounces* [avoird.]; Distilled Water *one gallon* [Imperial measure]. Dissolve the Carbonate of Potash in the Water; and, having heated the solution to the boiling point, in a clean iron vessel, gradually mix with it the Slaked Lime; and continue the ebullition for ten minutes with constant stirring. Then remove the vessel from the fire; and, when by the subsidence of the insoluble matter the supernatant liquor has become perfectly clear, transfer it by means of a siphon to a green-glass bottle furnished with an air-tight stopper. The sp. gr. is 1·058." *Br.*

The object of the first U. S. and of the British process is to separate carbonic acid from the carbonate or bicarbonate of potassa, so as to obtain the alkali in a caustic state. This separation of the carbonic acid is effected by hydrate of lime; and the chemical changes which take place are most intelligibly explained by supposing the occurrence of a double decomposition. The lime of the hydrate of

lime, by its superior affinity, combines with the carbonic acid, and precipitates as carbonate of lime; while the water of the hydrate of lime unites with the potassa and remains in solution as hydrate of potassa. The proportion indicated by theory for this decomposition would be 69·2 of the dry carbonate to 28 of lime, or one equivalent of each; but in practice it is found necessary to use an excess of lime. The bicarbonate is preferred in the U. S. process, as affording a purer product, being itself free from the contaminations usually found in the carbonate; and the application of heat to the solution of the bicarbonate is to drive off a portion of the carbonic acid and thus bring the salt to the state of a carbonate. The proportion of water employed has a decided influence on the result. If the water be deficient in quantity, the decomposing power of the lime, on account of its sparing solubility, will be lessened; and more of it will be required to complete the decomposition of the carbonate than if the solutions were more dilute. Straining must not be used; as it causes a prolonged contact with the air, and risk of the absorption of carbonic acid, and is apt, moreover, to introduce organic matter from the strainer into the solution. The direction to keep the solution in green glass bottles is judicious; as white flint glass is slightly acted on, and contaminates the solution with lead.*

As the solution of potassa is made by the manufacturing chemist in considerable quantities, the following details, taken from Berzelius, of the best mode of conducting the process, may not be without their use. Dissolve one part of carbonate of potassa in from seven to twelve parts of water in a bright iron vessel, and decant the solution after it has become clear by standing. Boil the solution in an iron vessel, and, while it is boiling, add at intervals small quantities of slaked lime, reduced to a thin paste with water; allowing the solution to boil a few minutes after each addition. One and a half parts of pure lime will be more than sufficient to decompose one part of the carbonate. When about half the hydrate of lime has been added, take out about a teaspoonful of the boiling solution, and, after dilution and filtration through paper, test it by adding it to some nitric acid, or by mixing it with an equal bulk of lime-water. If the solution has not been completely freed from carbonic acid, the first reagent will cause an effervescence, and the second a milky appearance; in either of which events the addition of the lime must be continued as before, until the above-mentioned tests give negative indications. In conducting the process, several advantages are gained by keeping the solution constantly boiling. One is that the carbonate of lime formed is in this way rendered granular and heavy, and more disposed to subside; another, that it prevents the precipitated carbonate from coalescing into a mass at the bottom of the vessel, an occurrence which causes the ebullition, when subsequently renewed, to take place imperfectly and by jerks; and a third, that any silica present is precipitated in combination with lime and potassa. The process here described is essentially the same with those introduced into the last editions of the Edinburgh and Dublin Pharmacopœias.

According to Prof. Wöhler, solution of pure hydrate of potassa for analytic purposes may be conveniently obtained by exposing for half an hour to a moderate red heat, in a copper crucible, one part of pure nitre, and two or three parts of copper cut into small pieces. The resulting mass, consisting of hydrate of potassa and black oxide of copper, is treated with water, and the solution

* For remarks by Prof. Redwood, of London, in relation to the preparation of this Solution, and for a new process for which various advantages are claimed, the reader is referred to the *London Pharmaceutical Journal* for March, 1861, p. 450. The following are the outlines of the process. Into a stoppered bottle of green glass is introduced a mixture of ℥viiss of slaked lime and three Imperial pints of distilled water: and to this mixture is added, in small quantities at a time, a solution of ℥viiss of carbonate of potassa in one Imperial pint of distilled water, the bottle being shaken for some minutes after each addition. After the last addition, continue the shaking until a portion of the filtered liquid no longer gives out carbonic acid, upon adding an excess of muriatic acid through calico.—*Note to the twelfth edition.*

poured into a narrow cylindrical vessel, where it is left until it gets perfectly clear by the deposition of the oxide of copper. It is then drawn off, and kept in well-stopped bottles. (*Chem. Gaz.*, Nov. 15, 1853, p. 429.) Graf and Riegel assert that hydrate of potassa, thus obtained, contains nitrate and nitrite of potassa: but Dr. A. Geuther found it perfectly pure, when the process was properly conducted. (*Chem. Gaz.*, June 1, 1856.) A pure hydrate may also be obtained by the process of Dr. Mohr, of Coblentz, which consists in precipitating solution of sulphate of potassa with caustic baryta, obtained from the nitrate. Thus procured, the alkali is entirely free from chlorine, silica, and sulphuric acid. (*Pharm. Journ.*, xvi. 310.)

Properties, &c. Solution of potassa is a limpid, colourless liquid, without smell, of an acrid caustic taste, and alkaline reaction. It acts rapidly on animal and vegetable substances, and, when rubbed between the fingers, produces a soapy feel, in consequence of a partial solution of the cuticle. It dissolves gum, resins, and extractive matter, and forms soap with oily and fatty bodies. The Br. solution is never pure, but contains either undecomposed carbonate, or free lime, in addition to minute portions of sulphate of potassa, chloride of potassium, silica, and alumina; impurities usually present in the carbonate of potassa used in their preparation. The U. S. solution, being obtained from the bicarbonate of potassa, is purer. Undecomposed carbonate may be detected in the manner explained in a preceding paragraph, and free lime by the production of a milky appearance on the addition of a few drops of carbonate of potassa, which precipitates the lime as a carbonate. When saturated with nitric acid, the solution should give little or no precipitate with carbonate of soda, chloride of barium, or nitrate of silver. The presence of lead is detected by a black precipitate produced by hydrosulphuret of ammonia. When solution of potassa is used as a test for diabetic urine, it should be free from lead, the presence of which renders the indications of the test ambiguous. (See *Wood's Practice of Med.*, 4th ed., ii. 586.) With bichloride of platinum it produces a yellow precipitate, showing that the alkali present is potassa. It is incompatible with acids, acidulous salts, and all metallic and earthy preparations held in solution by an acid; also with all ammoniacal salts, and with calomel and corrosive sublimate. The two officinal solutions of potassa vary in strength; the U. S. solution having the sp. gr. 1·065 and the Br. 1·058. These solutions are quite dilute; that of the U. S. Pharmacopœia, which is the strongest, containing only 5·8 per cent. of hydrate of potassa. On account of its strong attraction for carbonic acid, solution of potassa should be carefully preserved from contact with the air. In consideration of the change to which it is liable by keeping, it may sometimes be advantageously prepared extemporaneously, according to the second U. S. process, by dissolving the hydrate in water. B.

Medical Properties and Uses. Solution of potassa is antacid, diuretic, and antilithic. It has been much employed in calculous complaints, under the impression that it has the property of dissolving urinary concretions in the kidneys and bladder; but experience has proved that the stone once formed cannot be removed by remedies internally administered, and the most that the alkaline medicines can effect, is to correct that disposition to the superabundant secretion of uric acid, or the insoluble urates, upon which gravel and stone often depend. For this purpose, however, the carbonated alkalies are preferable to caustic potassa, as they are less apt to irritate the stomach, and to produce injurious effects when long continued. It has been proposed to dissolve calculi by injecting immediately into the bladder the solution of potassa in a tepid state, and so much diluted that it can be held in the mouth; but this mode of employing it has not been found to answer in practice. This solution has also been highly recommended in lepra, psoriasis, and other cutaneous affections; and is said to have proved peculiarly useful in scrofula; but in all these cases it probably acts sim-

ply by its antacid property, and is not superior to the carbonate of potassa or of soda. Externally it has been used, in a diluted state, as a stimulant lotion in rachitis and arthritic swellings, and, concentrated, as an escharotic in the bite of rabid or venomous animals. The dose is from ten to thirty minims, repeated two or three times a day, and gradually increased in cutaneous affections to one or two fluidrachms; but the remedy should not be too long continued, as it is apt to debilitate the stomach. It may be given in sweetened water or some mucilaginous fluid. Veal broth and table beer have been recommended as vehicles; but the fat usually present in the former would be liable to convert the alkali into soap, and the acid in the latter would neutralize it. In dyspeptic cases it may be associated with the simple bitters. In excessive doses it irritates, inflames, or corrodes the stomach. Oils and the milder acids, such as vinegar and lemon-juice, are the antidotes to its poisonous action. They operate by neutralizing the alkali.

LIQUOR POTASSÆ ARSENITIS. *U. S.* Liquor Arsenicalis. *Br.* *Solution of Arsenite of Potassa. Arsenical Solution. Fowler's Solution.*

"Take of Arsenious Acid, in small pieces, Bicarbonate of Potassa, each, *sixty-four grains;* Compound Spirit of Lavender *half a fluidounce;* Distilled Water *a sufficient quantity.* Boil the Arsenious Acid and Bicarbonate of Potassa, in a glass vessel, with twelve fluidounces of Distilled Water, until the Acid is entirely dissolved. To the solution, when cold, add the Compound Spirit of Lavender, and afterwards sufficient Distilled Water to make it measure a pint." *U. S.*

"Take of Arsenious Acid, Carbonate of Potash, each, *eighty grains:* Compound Tincture of Lavender *five fluidrachms* [Imperial measure]; Distilled Water *a sufficiency.* Place the Arsenious Acid and Carbonate of Potash in a flask with ten [fluid]ounces of the Water, and apply heat until a clear solution is obtained. Allow this to cool. Then add the Compound Tincture of Lavender, and as much Distilled Water as will make the bulk one pint [Imp. meas.]." *Br.* The sp. gr. of this solution is 1·009.

This preparation originated with the late Dr. Fowler, of Stafford, England, and was intended as a substitute for the celebrated remedy, known under the name of "the *tasteless ague drop.*" It is an arsenite of potassa dissolved in water, and is formed by the combination of the arsenious acid with the potassa of the bicarbonate or carbonate, the carbonic acid being evolved. In the present U. S. process, the bicarbonate has been substituted for the carbonate, probably because more readily obtained pure. Its eq. corresponds so nearly with that of arsenious acid that, practically, the equal quantities directed will serve the purposes of the formula. According to M. H. Buignet, ebullition disengages the carbonic acid slowly; so that, after four hours' boiling, the solution still retains about one-sixth of this acid. (*Journ. de Pharm.*, Dec. 1856, p. 440.) The name by which the preparation is designated in the U. S. Pharmacopœia is the most correct. It has, however, been denied that the carbonate of potassa is decomposed by the arsenious acid, which is supposed to be merely held by it in solution; and, in this view of the nature of the preparation, the British name of Arsenical Solution would be appropriate. The spirit of lavender is added to give it taste, and prevent its being mistaken for water. The U. S. preparation is of about the same strength as the British; for, although one-fourth more acid and alkali is taken in the latter formula, yet the Imperial pint is nearly one-fourth larger than the wine pint.

In making this preparation, care should be taken that the arsenious acid is

pure. This object is best secured by using the acid in small pieces instead of in powder. Sulphate of lime is a common impurity in the powdered acid, and if present will remain undissolved, and cause the solution to be weaker than it should be. Another insoluble impurity in the powdered acid is arsenite of lime, which is sometimes present to the amount of 25 per cent. (*Buignet.*) Hence, if the arsenious acid does not entirely dissolve, the solution must be rejected.

Properties. Solution of arsenite of potassa is a transparent liquid, having the colour, taste, and smell of the spirit of lavender. It has a strong alkaline reaction. It is decomposed by the usual reagents for arsenic, such as nitrate of silver, the salts of copper, lime-water, and sulphuretted hydrogen; and is incompatible with infusions and decoctions of cinchona. Before sulphuretted hydrogen will act, the solution must be acidulated with some acid, as the muriatic or acetic. If very long kept in flint glass, it is apt to suffer partial decomposition, exhaling a garlicky odour, and giving the inner surface of the bottle a metallic lustre, owing to the lead of the glass being revived. (Canavan, *N. Y. Journ. of Pharm.*, i. 131.) According to Dr. R. Fresenius, solutions of alkaline arsenites, by keeping, absorb oxygen from the air, and are in part converted into arseniates. Hence the propriety of keeping this solution in small bottles quite filled. Mohr states that the alkaline reaction of the officinal solution delays the change.

Medical Properties and Uses. This solution has the general action of the arsenical preparations on the animal economy, already described under the head of *Arsenious Acid.* Its liquid form makes it convenient for exhibition and gradual increase; and it is the preparation generally resorted to, when arsenic is given internally. It has been much employed in intermittent fever. Prof. Thomas D. Mitchell, of Jefferson Medical College, has given the result of his experience, as to its efficacy and safety in this disease, when exhibited in the large dose of fifteen or twenty drops three times a day. It is a valuable resource in the intermittents of children, who are with difficulty induced to swallow bark or even sulphate of quinia. The late Dr. Dewees related the case of a child only six weeks old, affected with a severe tertian, in which this solution was given with success. A fluidrachm was diluted with twelve fluidrachms of water; and of this six drops were given every four hours.

Fowler's solution is useful in many diseases. It has been employed with great success in lepra and other inveterate cutaneous affections. The late Dr. S. Calhoun published an account of five cases of nodes successfully treated by it; and Dr. Baer, of Baltimore, and the late Dr. Eberle afterwards gave it a trial in this affection, and obtained satisfactory results. Several cases of chorea, cured by it, are reported by Mr. Martin, Mr. Slater, and Dr. Gregory, in the *Medico-Chirurgical Transactions* of London. Two interesting cures of periodical headache, performed by the solution, were related by the late Dr. Otto, of Philadelphia, in the *North American Med. and Surg. Journal* (vols. iv. and v.). Mr. H. Hunt found it useful in menorrhagia, but prefers arsenious acid, as less apt to produce unpleasant effects. Dr. Fuller, of London, praises its effects in rheumatic gout, attended with turbid urine, in the dose of from eight to fifteen minims, conjoined with solution of potassa, or acetate of potassa. For an account of the successful use of Fowler's solution in five cases of snake bite, see *page* 25. A diluted solution, in the proportion of a fluidrachm to the fluidounce of water, has been used with advantage as a topical application to foul ulcers.

Each fluidrachm of the solution contains half a grain of arsenious acid. The average dose for an adult is ten drops two or three times a day. For the peculiar effects which it produces in common with the other arsenical preparations, the reader is referred to the article *Arsenious Acid.*

Duflos's antidote to the poisonous effects of Fowler's solution, and of the salts of the acids of arsenic generally, is the acetate of the sesquioxide of iron with excess of base, made by dissolving freshly precipitated sesquioxide in acetic acid

to saturation, adding an equal quantity of the oxide to the solution, and diluting the whole with water to the consistence of cream. B.

LIQUOR POTASSÆ CITRATIS. *U. S. Solution of Citrate of Potassa.*

"Take of Citric Acid *half a troyounce;* Bicarbonate of Potassa *three hundred and thirty grains;* Water *half a pint.* Dissolve the Acid and Bicarbonate in the Water, and strain the solution through muslin." *U. S.*

MISTURA POTASSÆ CITRATIS. *U. S.* LIQUOR POTASSÆ CITRATIS. *U. S.* 1850. *Mixture of Citrate of Potassa. Solution of Citrate of Potassa. Neutral Mixture.*

"Take of Lemon-juice, fresh, *half a pint;* Bicarbonate of Potassa *a sufficient quantity.* Add the Bicarbonate gradually to the Lemon-juice until the acid is completely saturated; then strain through muslin." *U. S.*

We regret that two preparations so nearly identical in character, and associated in the Pharmacopœia of 1850, should have been separated in the present edition. We consider them here together, because essentially connected in practice; one being substituted for the other according to circumstances unconnected with their real remedial effects, as the presence or absence of fresh lemons or limes in the market, the taste of the patient, &c. In the present formula for solution of citrate of potassa the volatile oil of lemons has been omitted; which we should also regret, were it not easy to supply the omission extemporaneously if required. Two minims of the oil, rubbed up with the citric acid before it is dissolved, will materially improve the flavour, and give the preparation a closer resemblance to the original neutral mixture made from lemon-juice, from which it was copied. In both the above preparations, the potassa of the bicarbonate unites with the citric acid, and the carbonic acid is liberated. A portion of the latter remains in the solution, and a portion escapes with effervescence. The result, therefore, is a solution of citrate of potassa in water impregnated with carbonic acid. When lemon-juice is employed, the solution has a greenish colour; but prepared with the pure acid it is colourless. In the U. S. Pharmacopœia of 1850, bicarbonate of potassa was substituted for the carbonate before used. As the preparation was formerly made, a flocculent precipitate was apt to exhibit itself in small quantity, owing to the silicate of potassa generally present as an impurity in the carbonate. This gave up its base to the citric acid, and the silica was deposited in the state of a hydrate. The bicarbonate is free from this impurity, and consequently hydrated silica is not thrown down; nevertheless, the solution is still directed to be filtered; a direction which may be useful, when fresh lemon-juice is used, by separating the undissolved matters of the juice, and in other instances is only surplusage. About 48 grains of the crystals of the bicarbonate, 33 grains of the pure and perfectly dry carbonate, or 45 grains of the hydrated carbonate found in the shops, are sufficient to saturate a fluidounce of good lemon-juice; but the strength of the juice is variable, and the carbonate is apt to absorb moisture from the air, so that precision as to quantities cannot be readily attained. Hence the propriety of the direction in the process for the neutral mixture, to add the alkaline carbonate to saturation. The point of saturation may be determined by the cessation of effervescence, the absence of either an acid or alkaline taste, and still more accurately by litmus paper, which should not be rendered bright-red by the solution, nor blue if previously reddened by an acid.

The inequality of strength in the lemon-juice renders the neutral mixture prepared with it more or less uncertain; though, if the apothecary select ripe and sound fruit, and express the juice himself, the preparation will be found to approach sufficiently near a uniform standard for all practical purposes. Nevertheless, if the physician wish absolute precision, he may order the neutral mixture to be made with crystallized citric acid, as directed in the first officinal formula;

or he may pursue the following plan suggested in former editions of this work. Dissolve two drachms of bicarbonate of potassa in two fluidounces of water; saturate the solution with good fresh lemon-juice, and strain; and, lastly, add enough water to make the mixture measure six fluidounces. A fluidounce of this solution may be given for a dose.

Another mode of preparing the neutral mixture, officinal in 1850, but omitted in the present edition of the Pharmacopœia, is simply to dissolve citrate of potassa in water, in the proportion of six drachms to half a pint. The preparation may be improved in flavour, and rendered more agreeable to the stomach, by rubbing a drop or two of oil of lemons with the six drachms of citrate before dissolving it, and substituting carbonic acid water for water as the menstruum.

Effervescing Draught. Under this name, the citrate of potassa is often prepared extemporaneously, and given in the state of effervescence. The most convenient mode of exhibition is to add to a fluidounce of a mixture consisting of equal parts of lemon-juice and water, half a fluidounce of a solution containing fifteen grains of carbonate of potassa, or twenty grains of the bicarbonate. Should effervescence not occur, as sometimes happens, when the carbonate is used, in consequence of the weakness of the lemon-juice, more of the juice should be added; as, unless sufficient acid is present to neutralize the potassa, part of the carbonate passes into the state of bicarbonate, and the gas is thus prevented from escaping. A solution of citric acid of the strength of that directed in the officinal formula may be substituted for lemon-juice, if this is not to be had. The fifteen grains of carbonate of potassa above mentioned are scarcely sufficient to saturate the lemon-juice, if of ordinary strength; but a little excess of the acid renders the preparation more agreeable to the taste. Some prefer the bicarbonate in the preparation of the effervescing draught, because it will always effervesce with lemon-juice, no matter what may be the strength of the latter. But this is an objection. The carbonate serves, by the absence of effervescence, to indicate when the lemon-juice is very weak in acid; and the defect may then be easily remedied by the addition of more juice. When the bicarbonate is used, if there should be a deficiency of acid, it is not discovered; and the patient takes a considerable portion of undecomposed bicarbonate, instead of the full quantity of citrate intended.

Medical Properties and Uses. The solution of citrate of potassa has long been used under the name of *neutral mixture*, *saline mixture*, or *effervescing draught*. It is an excellent refrigerant diaphoretic, adapted to almost all cases of fever with a hot dry skin, and especially to the paroxysms of our remittent and intermittent fevers. The *effervescing draught* is peculiarly useful. The carbonic acid serves to cover the taste of the citrate of potassa, and adds to the diaphoretic powers of the salt its own cordial influence upon the stomach. No preparation with which we are acquainted is equally efficacious in allaying irritability of stomach and producing diaphoresis in our remittent fevers. It is usually also very grateful to the patient. In order to increase the sedative and diaphoretic properties of the neutral mixture, it is customary to add to it a portion of tartar emetic; and a little sweet spirit of nitre will be found an excellent adjuvant in fevers with nervous disturbance. Should the solution irritate the bowels, as occasionally happens, it may be combined with a little laudanum or solution of sulphate of morphia. Sugar may be added if desired.

The dose of the officinal solution is a tablespoonful or half a fluidounce, which should be somewhat diluted when taken. The whole of each effervescing draught, prepared as above stated, is to be taken at once. Each dose should be repeated every hour, two, or three hours, according to the urgency of the symptoms. W.

LIQUOR POTASSÆ PERMANGANATIS. *Br. Solution of Permanganate of Potassa.*

"Take of Permanganate of Potash *four grains;* Distilled Water *one fluidounce.* Dissolve." *Br.*

This is a simple solution of permanganate of potassa, in the proportion, as nearly as may be, of one part by weight to 110 parts of water; and is intended to be of standard strength. But, while for some purposes it is too strong, for others it is too feeble; and we prefer M. Reveil's normal solution of 10 parts to 90, so that the solution shall contain 10 per cent. of the salt, which may be used of its full strength when required, or diluted more or less according to circumstances. For details on this point the reader is referred to the article on permanganate of potassa (*page* 684). The London solution is used as a gargle in fetid affections of the throat, and for washing the hands after dissections, in the proportion of one part to forty of water. W.

LIQUOR SODÆ. *U. S., Br. Solution of Soda.*

"Take of Carbonate of Soda *twenty-six troyounces;* Lime *eight troyounces;* Distilled Water *a sufficient quantity.* Dissolve the Carbonate in three pints and a half of Distilled Water, and heat the solution to the boiling point. Mix the Lime with three pints of Distilled Water, and, having heated the mixture to the boiling point, add it to the solution of the Carbonate, and boil for ten minutes. Then transfer the whole to a muslin strainer, and, when the liquid portion has passed, add sufficient Distilled Water, through the strainer, to make the strained liquid measure six pints. Lastly, keep the liquid in well-stopped bottles of green glass. Solution of Soda has the sp. gr. 1·071, and contains 5·7 per cent. of hydrate of soda." *U. S.*

The British Pharmacopœia takes of Carbonate of Soda *twenty-eight ounces* [avoirdupois]; Slaked Lime *twelve ounces* [avoird.]; Distilled Water *one gallon* [Imperial measure], and prepares the Solution in the manner directed for Liquor Potassæ. The sp. gr. of the British solution is 1·047; and the proportion of hydrated soda contained in it is 4·41.

Solution of soda is prepared in the same way as solution of potassa. By a double decomposition between carbonate of soda and hydrate of lime, there are formed hydrate of soda in solution, and carbonate of lime which precipitates. In both the processes an excess of lime is used, which is necessary to ensure a full decomposition of the carbonate. "One fluidounce [of the British solution] requires for neutralization 47 measures of the *volumetric solution of oxalic acid.*" *Br.*

Properties, &c. Solution of soda, sometimes called solution of *caustic* soda, is a colourless liquid, having a caustic taste and alkaline reaction. Its properties and tests are the same as those of solution of potassa, with the exception that no precipitate is produced by bichloride of platinum or tartaric acid. The alkali dissolved must be viewed as hydrate of soda, consisting of one eq. of soda 31·3, and one of water 9 = 40·3.

Off. Prep. Soda Caustica, *Br.;* Sodæ Valerianas, *U. S.* B.

LIQUOR SODÆ ARSENIATIS. *Br. Solution of Arseniate of Soda.*

"Take of Arseniate of Soda (rendered anhydrous by a heat not exceeding 300°) *four grains;* Distilled Water *one fluidounce.* Dissolve." *Br.*

This is simply an officinal form for the administration of arseniate of soda. (See *Sodæ Arsenias.*) The salt is directed to be dried, in order, we presume, that the solution may be of a uniform strength; as, from the mode in which the arseniate of soda is ordered to be prepared, it is scarcely possible that it should always contain precisely the same quantity of water of crystallization. It is important in drying it to limit the heat to 300°, lest a portion of the arsenic should be volatilized. The commencing dose is from three to five minims or drops, to

be very cautiously increased if necessary. Its arsenical strength is about the same as that of the British solution of arsenite of potassa. W

LIQUOR SODÆ CHLORINATÆ. *U.S.* Liquor Sodæ Chloratæ. *Br. Solution of Chlorinated Soda. Solution of Chloride of Soda. Labarraque's Disinfecting Liquid.*

"Take of Chlorinated Lime *twelve troyounces;* Carbonate of Soda *twenty-four troyounces;* Water *twelve pints.* Dissolve the Carbonate of Soda in three pints of the Water, with the aid of heat. Triturate the Chlorinated Lime, a little at a time, with small portions of the Water, gradually added, until a smooth, uniform mixture is obtained. Mix this intimately with the remainder of the Water, and set the mixture aside for twenty-four hours. Then decant the clear liquid, and, having transferred the residue to a muslin strainer, allow it to drain until sufficient liquid has passed to make, with the decanted liquid, eight pints. Mix the liquid thoroughly with the Solution of Carbonate of Soda, transfer the mixture to a muslin strainer, and allow it to drain, adding water, if necessary, towards the close, until eleven pints and a half of liquid have passed. Lastly, keep the liquid in well-stopped bottles, protected from the light." *U. S.* The sp. gr. of this solution is 1·045.

"Take of Carbonate of Soda *twelve ounces* [avoirdupois]; Chloride of Sodium *four ounces* [avoird.]; Black Oxide of Manganese, in powder, *three ounces* [avoird.]; Sulphuric Acid *two fluidounces and a half* [Imperial measure]; Distilled Water *forty-four fluidounces* [Imp. meas.]. Reduce the Carbonate of Soda to powder, dissolve it in thirty-six [fluid]ounces of the Water, and put the solution into a glass vessel. Mix the Chloride of Sodium and the Oxide of Manganese, place them in a retort, and add to them the Sulphuric Acid, previously mixed with three [fluid]ounces of the Water, and allow to cool. Heat the mixture gradually, and pass the evolved chlorine through a wash bottle containing five [fluid]ounces of the Water, and afterwards into the solution of carbonate of soda. When the disengagement of chlorine has ceased, transfer the solution to a stoppered bottle, and keep it in a cool and dark place." *Br.* The sp. gr. of this solution is 1·103.

This solution was first brought into notice as a disinfecting agent by Labarraque, an apothecary of Paris. It was afterwards found to possess valuable therapeutic properties. The *U. S.* process is that of Payen, adopted in the French Codex of 1837. It consists in decomposing a solution of carbonate of soda by one of chlorinated lime. Carbonate of lime is precipitated and the chlorinated soda remains in solution. The proportion employed gives an excess of carbonate of soda, the presence of which renders the solution more permanent. The British process is that of Labarraque. All the chlorine generated from the prescribed quantity of materials for forming that gas, is passed into the solution of carbonate of soda; and, when the chlorine is limited to this quantity, no carbonic acid is disengaged. The chlorine is first passed through water to free it from muriatic acid, which, if suffered to come over, would convert the alkali into common salt.

Properties. The *U. S.* solution is transparent, of a greenish-yellow colour, a faint smell of chlorine, a sharp saline taste, and an alkaline reaction. With lime-water it yields a precipitate of carbonate of lime, known to be a carbonate by its dissolving with effervescence in an acid. This precipitate is caused by the excess of carbonate of soda. Owing to the presence of loosely combined chlorine, it rapidly destroys the colour of sulphate of indigo. It produces a copious, light-brown precipitate with the sulphate of iron. The British solution is a colourless alkaline liquid, of an astringent taste, and a feeble smell of chlorine. With muriatic acid it effervesces, and evolves chlorine and carbonic acid, and forms a solution which is not precipitated by bichloride of platinum, thus showing the absence of potassa. It is not precipitated by oxalate of ammonia,

showing that it contains no lime. "One fluidrachm, added to a solution of 20 grains of iodide of potassium in four fluidounces of water, and acidulated with two fluidrachms of hydrochloric acid, requires for the discharge of the brown colour which the mixture assumes, forty-three measures of the *volumetric solution of hyposulphite of soda.*" (*Br.*) This test is intended to determine the chlorine strength of the solution. The hydrochloric acid liberates the chlorine, which then separates from the iodide of potassium an equivalent quantity of iodine, by which the solution is rendered brown; and the iodine being converted into hydriodic acid by the hyposulphite of soda, the solution again becomes colourless. The quantity of the solution of the latter salt required to bleach the liquid measures the proportion of iodine, and this that of the chlorine which separates it. The colour of turmeric is first rendered brown, and afterwards destroyed. When it is boiled, chlorine is not given off, nor is its bleaching property sensibly impaired; and, when carefully evaporated, a mass of damp crystals is obtained, which, when redissolved in water, possess the properties of the original liquid. Both solutions, when exposed to the air, absorb carbonic acid and slowly evolve chlorine. It is on this property of gradually evolving chlorine that their disinfecting power depends.

Nature and Composition. The chemical nature of these solutions is different. Assuming the chlorinated lime to be essentially hypochlorite of lime with chloride of calcium (see *page* 186), the U. S. solution, after decantation from the precipitated carbonate of lime, will contain *hypochlorite of soda* with *chloride of sodium*. $CaO,ClO+CaCl$ and $2(NaO,CO_2)=NaO,ClO+NaCl$ and $2(CaO,CO_2)$. Besides these there will be present more or less *carbonate of soda*, according as there happens to be in the chlorinated lime less or more chlorine to decompose it. In all cases, however, there will be an excess of carbonate of soda; as the best chlorinated lime does not contain sufficient chlorine to effect its entire decomposition, in the proportion in which it is taken in the formula. The constitution of the British preparation is more complicated. As it is a peculiarity in its formation that no carbonic acid is evolved, it is necessary to assume the presence of all the carbonic acid of the carbonate of soda; and hence it is considered to be a combination of *hypochlorite of soda*, *chloride of sodium*, and *bicarbonate of soda*. The reaction is supposed to take place between four eqs. of carbonate of soda and two of chlorine. By a transfer of carbonic acid from two eqs. of carbonate to the remaining two eqs. of the same salt, two eqs. of bicarbonate are formed, and two of soda left. The sodium and oxygen of one eq. of soda unite, each, with one eq. of chlorine, so as to form one eq. of chloride of sodium, and one of hypochlorous acid. This acid then unites with the remaining eq. of soda to form hypochlorite of soda. The view here taken makes the U. S. and British solutions analogous in constitution; but differing in one containing the carbonate, the other the bicarbonate of soda. In the latter, half the soda is bicarbonated; in the former, from a half to a third is monocarbonated, according to the quality of the chlorinated lime used. According to Millon's view, both solutions contain *oxychloride of sodium*, $Na\left\{\begin{matrix}O\\Cl_2\end{matrix}\right.$, or, which is the same thing, bichloride of soda (NaO,Cl_2); thus making the compound assimilate in constitution to the teroxide of sodium (NaO_3). On Millon's view, one eq. of carbonate of soda would decompose two of chloride of lime, with the result of forming one eq. of bichloride of soda, one of carbonate of lime, and one of free lime. $2(CaO,Cl)$ and $NaO,CO_2=NaO,Cl_2$ and CaO,CO_2 and CaO. M. Millon's view doubles the proportion of the chlorine to the soda. Mr. B. Kavanagh, of Dublin, finds that a solution of alum has its alumina precipitated upon being added to the British chlorinated soda liquid, without effervescence of carbonic acid, but with the evolution of chlorine on the application of heat. Hence he infers that the soda, not combined with carbonic acid in the preparation, is

united with chlorine and not with hypochlorous acid, and, accordingly, conceives that he has proved the correctness of Millon's views. Upon the whole, analyses are wanting before we can determine the true constitution of the officinal solutions of chlorinated soda. The British solution, though made on Labarraque's plan, is considerably stronger than his preparation; for in the British process the carbonate is dissolved in about three times its weight of water, before the chlorine is transmitted; whereas Labarraque dissolved it in four times its weight.

Medical Properties and Uses. Solution of chlorinated soda is stimulant, antiseptic, and resolvent. Internally it has been employed in diseases termed *putrid* or *malignant*, as typhus fever, scarlatina maligna, &c. The conditions which indicate the propriety of its use are great prostration of strength, fetid evacuations, and dry and furred tongue. Under these circumstances it promotes urine, creates a moisture on the skin, and improves the secretions and evacuations. It has also been given in dysentery accompanied with peculiarly fetid stools, in dyspepsia attended with putrid eructations, and in glandular enlargements and chronic mucous discharges. Other diseases in which it has been recommended, are secondary syphilis, scrofula, bilious disorders, and chronic diseases of the skin. M. Chailly speaks in praise of it in suppressed or deficient menstruation. In asphyxia from sulphuretted hydrogen it forms, like chlorinated lime, an efficacious antidote. The dose is from thirty drops to a teaspoonful, given in a cupful of water or mild aqueous liquid, and repeated every two or three hours.

As a local remedy it is found useful in all affections attended with fetor, such as gangrenous, cancerous, scrofulous, and syphilitic ulcers, ulceration of the gums, carbuncle, ozæna, mortification, putrid sorethroat, &c. In these cases it is applied as a gargle, wash, ingredient of poultices, or imbibed by lint. In the sloughing of the fauces occurring in severe cases of scarlatina, Dr. Jackson, late of Northumberland, Pa., found it efficacious, used as a gargle, or injected into the throat. In small-pox Mr. John Gabb employed this solution with great benefit, as a wash and gargle for the mouth and throat, and as an application to the skin to allay itching. In the sore-mouth from ptyalism, it forms a good mouth-wash, when diluted with eight parts or more of water. In fetid discharges from the vagina, uterus, and bladder, it has been employed with advantage as an injection, diluted with from fifteen to thirty parts of water for the vagina and uterus, and with sixty parts when the object is to wash out the bladder by means of a double cannula. The solution of chlorinated soda has also been applied successfully to burns, and to cutaneous eruptions, particularly psoriasis, tinea capitis, scabies, and obstinate herpetic affections. In these cases it is diluted with from ten to thirty parts of water, the strength varying according to circumstances. For the cure of sore nipples, Dr. Chopin found nothing so successful as frequently repeated lotions with this solution.

Solution of chlorinated soda is a powerful disinfectant, better suited for disinfecting operations on a small scale than chlorinated lime. In the chambers of the sick, especially with infectious diseases, it is highly useful, sprinkled on the floor or bed, and added to the vessels intended to receive the excretions.

Off. Prep. Cataplasma Sodæ Chloratæ, *Br.* B.

LIQUOR STRYCHNIÆ. *Br. Solution of Strychnia.*

"Take of Strychnia, in crystals, *four grains;* Dilute Hydrochloric Acid *six minims;* Rectified Spirit *two fluidrachms;* Distilled Water *six fluidrachms.* Mix the Hydrochloric Acid with four [flui]drachms of the Water, and dissolve the Strychnia in the mixture by the aid of heat. Then add the Spirit and the remainder of the Water." *Br.*

This is in fact a solution of the muriate of strychnia. The spirit is added for its preservation. Two fluidrachms of it contain a grain of strychnia, and the commencing dose is ten minims, equal to one-twelfth of a grain of the alkaloid. W.

LITHIA.

Preparation of Lithia.

LITHIÆ CITRAS. *Br. Citrate of Lithia.*

"Take of Carbonate of Lithia *fifty grains;* Citric Acid, in crystals, *ninety grains;* Warm Distilled Water *one fluidounce.* Dissolve the Citric Acid in the Water, and add the Carbonate of Lithia, in successive portions, applying heat until effervescence ceases, and a perfect solution is obtained. Evaporate by a steam or sand-bath till water ceases to escape, and the residue is converted into a viscid liquid. This should be dried in an oven or air-chamber at the temperature of about 240°, then rapidly pulverized, and enclosed in a stoppered bottle." *Br.*

The British Pharmacopœia gives, as the composition of citrate of lithia, three eqs. of lithia and one of citric acid ($3LO,C_{12}H_5O_{11}$); this acid being tribasic. The eq. of carbonate of lithia being 37, and three eqs. entering into the constitution of the salt, 111 parts of the carbonate will of course require 201 parts or one eq. of crystallized citric acid for saturation. Consequently, to saturate the 50 grains of carbonate of lithia directed by the Pharmacopœia, 90·54 grains of the crystallized acid will be required; so that there is a slight deficiency on the part of the acid; whereas it should be in slight excess, and, according to Mr. Squire, 100 grains of the acid should be used instead of 90 grains.

Citrate of Lithia, thus prepared, is in the form of a white powder, deliquescent, and soluble, without residue, in 2·5 parts of water. (*Squire.*) Heated to redness it blackens, evolving inflammable gases; and the residue, neutralized by hydrochloric acid, yields with rectified spirit a solution which burns with a crimson flame. (*Br.*) This test proves that the base is lithia, and the acid organic. That the salt is a citrate will be shown by its solution becoming turbid when boiled with lime-water, but clear again on cooling. (*Brande and Taylor.*) "Twenty grains of it, burned at a low red heat, with free access of air, leave 10·6 grains of white residue." (*Br.*) In other words, 20 grains of the salt yield 10·6 grains of carbonate of lithia; for all the acid with its carbon must be consumed in the process. If the salt consist, as stated in the Pharmacopœia, of 3 eqs. of lithia = 45, and one eq. of citric acid ($C_{12}H_5O_{11}$) = 165, without water, 210 parts of it should yield 111 parts of the carbonate, which is almost exactly the result given by the Pharmacopœia; so that the citrate must be considered as anhydrous.

Medical Properties and Uses. These are essentially the same as those of the carbonate, as, before entering the circulation, the citric acid is decomposed, and the lithia circulates with the blood, and passes out with the urine in the form of carbonate. While thus capable of producing the antacid, antilithic, and diuretic effects of the carbonate, it has the advantages over that salt of having a less disagreeable taste, and of being less disposed to irritate the stomach; the same advantages that, in many instances, the citrate of potassa has over the carbonate of that alkali. The dose is stated at from five to ten grains; but probably much more might sometimes be given with advantage, especially when employed with the object of dissolving depositions of urate of soda. W.

MAGNESIA.

Preparations of Magnesia.

MAGNESIA. *U. S.* MAGNESIA LEVIS. *Br. Magnesia.*

"Take of Carbonate of Magnesia *a convenient quantity.* Put it into an earthen vessel, and expose it to a red heat for two hours, or until the carbonic acid is entirely expelled." *U. S.*

In the British Pharmacopœia directions are given for preparing two forms of magnesia, one called *Magnesia Levis*, or *Light Magnesia*, from the *Light Carbonate*, and the other simply *Magnesia* from the heavy carbonate, which it designates simply as *Carbonate of Magnesia*. It is the former which corresponds with our ordinary magnesia.

"Take of Light Carbonate of Magnesia *four ounces*. Introduce the Carbonate of Magnesia into a Cornish or Hessian crucible closed loosely by a lid, and let this be exposed to a low red heat as long as a little of the powder, taken from the centre of the crucible, when cooled and dropped into dilute sulphuric acid, gives rise to effervescence. The product should be preserved in corked bottles." *Br.*

Magnesia. *Br.* This is directed, in the British Pharmacopœia, to be prepared precisely in the same manner as magnesia, using, however, the heavy carbonate, named by it Carbonate of Magnesia.

By exposure to a red heat, the water and carbonic acid of the carbonate of magnesia are expelled, and the earth is obtained pure. According to Dr. Black, the carbonate loses seven-twelfths of its weight by calcination. Brande says that the loss varies from 50 to 60 per cent., of which from 15 to 20 per cent. is water. About the close of the process the earth exhibits a luminous or phosphorescent appearance, which is said to be a good criterion of its freedom from carbonic acid. (*Duncan.*) A more certain indication, however, is the absence of effervescence when muriatic acid is added to a little of the magnesia, previously mixed with water. It is an error to suppose that a very intense heat is requisite in the calcination. The temperature of ignition is sufficient for the expulsion of the water and carbonic acid, and any increase serves only to render the magnesia harder, denser, less readily soluble in acids, and consequently less useful as a medicine. In order to ensure a pure product, care should be taken that the carbonate employed be free from lime. It should be rubbed to powder before being introduced into the pot or crucible; and, as in consequence of its levity it occupies a very large space, the plan has been proposed of moistening and compressing it in order to reduce its bulk; but the French pharmaceutical writers direct that the vessels employed should be sufficiently large to contain a considerable quantity of the carbonate, without the necessity of resorting to compression.* The officinal direction, to keep the magnesia, after it has been prepared, in well-stopped glass vessels, is founded on the fact that it absorbs carbonic acid and water from the air; but, as the absorption of the acid goes on very slowly, and that of water does not injure the preparation, the caution is often neglected in the shops. The great bulk of the earth renders its introduction into small bottles inconvenient. A four ounce bottle holds only about an ounce of the purest and finest magnesia. But its specific gravity is greatly increased by trituration; and four times the quantity may be thus got into the same space. The density of *Henry's magnesia*, which is at least four times that of the earth prepared in the ordinary way, has been ascribed to this cause. It has also been attributed to the influence of intense heat employed in the calcination. The conjecture has even been advanced, that this magnesia, which has enjoyed so great a popularity in

* In a paper by M. A. Vée (*Journ. de Pharm.*, Avril, 1860, p. 84), it is stated that the magnesia of commerce, in consequence of imperfect preparation, is often found dense, granular, harsh, and of difficult solubility in the acids. To remedy this inconvenience the only method heretofore known was to prepare it in small quantities, and to stir the magnesia during calcination with an iron spoon. The difficulty in preparing it properly on the large scale depends upon the unequal action of the heat on large masses, so that the outer part becomes heated in excess before the inner is sufficiently so. To remedy this inconvenience M. Vée uses a furnace and crucible of a peculiar shape, so arranged that the magnesia may not be in layers thicker than seven centimetres (2·7 inches), may be exposed equably to heat, and not longer exposed than may be necessary for its decomposition. For an account of the apparatus, and of the proper method of managing the process, the reader is referred to the *Am. Journ. of Pharm.*, Nov. 1862, p. 522.—*Note to the twelfth edition.*

England and this country, is prepared by precipitating a solution of sulphate of magnesia by caustic potassa; as the earth afforded by this plan is comparatively dense. It is asserted that the magnesia, prepared from the carbonate procured by precipitating the sulphate of magnesia with carbonate of soda, is softer to the touch, and bears a closer resemblance to Henry's than that prepared from the ordinary carbonate. The fact is explained by the presence in common magnesia of a little sulphate of potassa, from which it is difficult entirely to free it in consequence of the sparing solubility of this salt, and of a portion of silica, which originally existed in the carbonate of potassa employed to decompose the sulphate of magnesia, and of which the carbonate of soda is destitute. According to Mr. Richard Phillips, jun., if equivalent quantities of crystallized sulphate of magnesia and crystallized carbonate of soda be boiled together in water, the mixture evaporated to dryness, the residual salts calcined, and the sulphate of soda dissolved out by water, the magnesia obtained will be dense. (See *Am. Journ. of Pharm.*, xvi. 118.) By packing the carbonate closely in the crucible, or by moistening and then compressing it strongly in a cloth, before calcination, a heavy magnesia is obtained. The advantages of Henry's magnesia, independently of the convenience of its less bulk, are its greater softness, and more ready miscibility with water. Preparations similar to Henry's are made by T. J. Husband and by Charles Ellis, of Philadelphia, and sold under the names respectively of *Husband's* and of *Ellis's Magnesia.**

* The three kinds of heavy magnesia sold in our market have been examined by Prof. Procter, with the following results. All are heavier than common magnesia, more readily miscible with water, smoother upon the tongue, and of a less quickly developed taste; but they differ in these respects, Henry's standing first, Husband's second, and Ellis's last. But the two latter are much more readily acted on by acids than Henry's, differing in this respect little from each other. Both, moreover, though less readily miscible with water than Henry's, are longer retained in suspension, and Ellis's exceeds Husband's in this quality. In reference, therefore, to mere facility of administration and to taste, it appears that the imported magnesia has the advantage; but for forming liquid mixtures, and for rapidity of antacid action, the American are preferable. Husband's contained 7 per cent. of combined water; the two others lost at a red heat only seven-tenths of one per cent. (*Am. Journ. of Pharm.*, xxii. 383.)

Dr. Pereira found *light magnesia*, under the microscope, to exhibit the same forms observed in the light carbonate; namely, one portion was amorphous and of a flocculent or granular consistence, and another was composed of fragments of prismatic crystals; while the *heavy magnesia* was homogeneous, exhibiting no traces of crystals, and consisting of minute granules more or less cohering into small soft balls or masses. (*Pharm. Journ.*, viii. 235.)—*Note to the ninth edition.*

In reference to the preparation of heavy magnesia, Mr. T. H. Barr, after trying various methods, obtained the best results either by precipitating a hot concentrated solution of sulphate of magnesia with a like solution of carbonate of soda, or by decomposing chloride of magnesium by heat. (*Am. Journ. of Pharm.*, xxvi. 193.)

Mr. Thomas Weaver proposes the following ready method of preparing a heavy magnesia, which, as we have been informed, yields a good product, having not only the recommendation of density, but that also of smoothness, which is a no less desirable quality. "Take of sulphate of magnesia ℥iv, ℥ij; *bi*carbonate of soda ℥iij. Dissolve the sulphate in six ounces of water, add a few drops of nitric acid, and boil for 15 or 20 minutes; then add sufficient carbonate of soda, dissolved in a little water, to produce a slight precipitate, and continue boiling for some time; filter, and set aside to cool. Triturate the *bi*carbonate of soda with about eight ounces of cold water, and add it to the cold solution of sulphate of magnesia. After frequent agitation, filter, transfer to a porcelain capsule, and boil quickly till reduced to a small bulk. Collect the precipitate on a filter, wash thoroughly, and, when nearly dry, transfer to a crucible free from iron, and calcine, bearing in mind the suggestion of Mr. Barr, that a low heat just approaching redness, and long continued, will ensure a much finer product than a high heat for a short time." The object of the nitric acid is to peroxidize any iron present in the sulphate, and the subsequent addition of carbonate of soda, followed by ebullition, is to precipitate the ferruginous oxide. Cold solutions of bicarbonate of soda and sulphate of magnesia do not react on each other; but, when the excess of carbonic acid is driven off by boiling, a precipitation takes place of carbonate of magnesia, which affords a denser magnesia by calcination than can be obtained by the use of carbonate of soda. (*Am. Journ. of Pharm.*, xxviii. 214.)—*Note to the eleventh edition.*

Properties, &c. Magnesia is a very light, white, inodorous powder, of a feeble alkaline taste. Its sp. gr. is commonly stated at 2·3. It was deemed infusible, till melted by means of the compound blowpipe of Dr. Hare. Water sprinkled upon it is absorbed to the extent of about 18 per cent., but with scarcely any increase of temperature. It is almost insoluble, requiring, according to Dr. Fyfe, 5142 parts of water at 60°, and 36,000 parts of boiling water for solution. Water thus impregnated has no effect on vegetable colours; but magnesia itself produces a brown stain by contact with moistened turmeric paper. Magnesia is a metallic oxide, consisting of one equivalent of magnesium 12, and one of oxygen 8=20. *Magnesium* is a white, very brilliant metal, resembling silver, malleable, fusible at a low temperature, and convertible into magnesia by the combined action of air and moisture. There is a hydrate of magnesia consisting of one equiv. of the earth and one of water. Magnesia forms with nitric and muriatic acids, salts which are soluble in alcohol, and very deliquescent. It is precipitated from its saline solutions by the pure alkalies in the state of a hydrate, and by the carbonates of potassa and soda as a carbonate; but it is not precipitated by the alkaline bicarbonates, nor by common carbonate of ammonia.

Magnesia is liable to contain, as impurities, carbonate of magnesia, lime, alumina, silica, and small quantities of the soluble salts employed or produced in the preparation of the carbonate from which it is procured. The presence of carbonate of magnesia is indicated by effervescence when the earth is dissolved in muriatic acid. Lime, which is a very frequent impurity, and imparts to the magnesia a more strongly alkaline and more disagreeable taste, is detected by oxalate of ammonia or bicarbonate of potassa. Neither of these salts disturbs a neutral solution of pure magnesia in a dilute acid; but, if lime is present, both produce a precipitate, the former of oxalate, the latter of carbonate of lime. As magnesia is completely dissolved by muriatic acid, silica and other impurities insoluble in that acid would be left behind. Alumina is indicated by the production of a precipitate when ammonia is added in excess to a solution of fifty grains of magnesia in a fluidounce of muriatic acid. (*Christison's Dispensatory.*) If the magnesia contain a soluble sulphate or carbonate, chloride of barium will reveal it by producing a precipitate with water digested on the magnesia.

Medical Properties and Uses. Magnesia is antacid and laxative; and is much used, under the name of *calcined magnesia*, in dyspepsia, sick headache, gout, and other complaints attended with sour stomach and constipation. It is also a favourite remedy in the complaints of children, in which acidity of the primæ viæ is often a prominent symptom. Its antacid properties render it useful in gravel attended with an excessive secretion of uric acid. Its advantages over carbonate of magnesia are that it may be given in a smaller dose, and does not occasion flatulence. The dose as a laxative is from thirty grains to a drachm; as an antacid merely, or antilithic, from ten to thirty grains twice a day. When it meets with no acid, it is apt to linger in the stomach or bowels, and may in that case be followed by lemonade. It should be administered in water or milk, and thoroughly triturated so as to render the mixture uniform. If mixed with less than 14 or 15 times its weight of water, and allowed to stand for a day or two, magnesia is apt to form a more or less concrete mass, owing to the production of a hydrate of the earth, and the solidification of a portion of the water. This change does not take place, or at least takes place much less readily, when magnesia already saturated with moisture is employed instead of that freshly calcined. It has been conjectured that anhydrous magnesia might prove injurious in the stomach by solidifying its liquid contents; and the earth which has become saturated with moisture by exposure to a damp air is preferably recommended. Freshly precipitated hydrate of magnesia will serve as an antidote to arsenious acid, though less efficient than hydrated sesquioxide of iron.

MELLITA.

Preparations of Honey.

Honey is used in pharmacy chiefly as the vehicle of more active medicines. It is said to have this advantage over syrup, that its preparations are less apt to become candied; but, as it contains principles which disagree with the stomach in many persons, and as its variable consistence prevents the same exact precision in regard to proportion as is attainable with a solution of pure sugar, it is at present little employed. The preparations in which honey and vinegar are combined are called *Oxymels.* The *Oxymel of Squill,* of the former U. S. and London Pharmacopœias, has been omitted in the existing editions of the two national codes.

Medicated honeys are of a proper consistence, if, when a small quantity, allowed to cool upon a plate, is divided by the edge of a spoon, the portions do not readily coalesce. A more accurate criterion, however, is their specific gravity, which should be 1·319 (35° B.) at ordinary temperatures, and 1·261 (30° B.) at the boiling point of water. The specific gravity is most readily determined by means of the saccharometer. W.

MEL DESPUMATUM. *U. S.* Mel Depuratum. *Br. Clarified Honey.*

"Take of Honey *a convenient quantity.* Melt it by means of a water-bath, and then remove the scum." *U. S.*

"Take of Honey *five pounds.* Melt the Honey in a water-bath, and strain, while hot, through flannel previously moistened with warm water." *Br.*

Honey, by the heat of the water-bath, becomes so fluid that the wax and other lighter impurities which it contains rise to the surface, and may be skimmed off; while the heavier substances which may have been accidentally or fraudulently added, such as sand or other earth, sink to the bottom.

The following method of clarifying honey has been practised in France. Take of white honey 3000 parts; water 750 parts; carbonate of lime, powdered and washed, 96 parts. Mix them in a suitable vessel, and boil for three minutes, stirring constantly. Then add 96 parts of animal charcoal, previously washed, heated to redness, powdered, and sifted, and boil for a few minutes. Lastly, add the whites of two eggs beat up with 500 parts of water, and bring the liquid to the boiling point. Withdraw the vessel from the fire, and, after the mixture has cooled for 15 minutes, strain it through flannel, and repeat the straining till the liquid passes perfectly clear. Should it not have a due consistence, it should be concentrated sufficiently by a quick boiling. The carbonate of lime serves to saturate any acid in the honey, which might favour the formation of glucose, and thus increase the tendency to granulation.

The French Codex simply directs six pounds of white honey to be heated with two pounds of water, skimmed, concentrated to 30° B. while boiling hot, and then strained through flannel.

The following method of clarifying honey is recommended by André von Hirschberg. Boil 25 lbs. of honey, to which half the quantity of water has been added, with a pulp obtained by stirring three sheets of white blotting-paper with water, over a slow fire, till the paper is reduced to minute fibres. When the mixture cools, put it into a woollen filtering bag, previously moistened, and allow the honey to pass. It comes away quite clear. The paper pulp may then be washed, and the dark liquid which passes, evaporated by a water-bath to the proper consistence. (See *Pharm. Journ.*, ix. 543.)

Another process, recommended by A. Hofmann, is to dissolve 28 lbs. of honey

in twice its weight of water, heat the solution to the boiling point, and then add a solution of three drachms of gelatin in three times its weight of water, and afterwards an aqueous solution of one drachm of tannin, or an infusion of two drachms of galls. The mixture is to be well stirred, and kept hot for an hour Lastly, seven-eighths of the honey may be drawn off clear, the remainder filtered through flannel, and the whole evaporated. (*Ibid.*, xv. 121.)

Honey clarified with carbonate of lime and animal charcoal, as in the first process described, is as clear and colourless as syrup made with sugar, but still retains a peculiar flavour. It is less disposed to ferment than crude honey, and is said not to be so liable to produce griping pain when swallowed.

S.;* Pilulæ Quiniæ Sulphatis, *U. S.;* Tinctura Cardamomi Composita, *U. S.;* Tinctura Opii Camphorata, *U. S.* W.

MEL ROSÆ. *U. S.* *Honey of Roses.*

"Take of Red Rose, in moderately fine powder, *two troyounces;* Clarified Honey *twenty-five troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with half a fluidounce of Diluted Alcohol, pack it firmly in a conical glass percolator, and gradually pour Diluted Alcohol upon it until six fluidrachms of filtered liquid have passed. Set this aside, and continue the percolation until half a pint more of liquid is obtained. Evaporate this, by means of a water-bath, to ten fluidrachms, add the reserved liquid, and mix the whole with the Clarified Honey." *U. S.*

Though one of the officinals in the late London and Edinburgh Pharmacopœias, the Honey of Roses has been dropped in the British.

The U. S. formula is based on that of Prof. Grahame, of Baltimore. (See *Am. Journ. of Pharm.*, Sept. 1859, p. 443.) The object in reserving a portion of the first tincture, in the process, is to avoid the evaporation of the volatile oil in the concentration of the infusion, and thus to preserve the flavour as well as the astringency of the roses. Honey of roses forms a pleasant addition to the gargles employed in inflammation and ulceration of the mouth and throat. W.

MEL SODÆ BORATIS. *U. S.* Mel Boracis. *Br.* *Honey of Borate of Soda. Honey of Borax.*

"Take of Borate of Soda, in fine powder, *sixty grains;* Clarified Honey *a troyounce.* Mix them." *U. S.*

"Take of Borax, in fine powder, *sixty-four grains;* Clarified Honey *an ounce.* Mix." *Br.*

This preparation might well be left to extemporaneous prescription. It is used in the thrush of infants, and aphthous ulcerations of the mouth. W.

OXYMEL. *Br.* *Oxymel.*

"Take of Clarified Honey *forty ounces* [avoirdupois]; Acetic Acid *five fluidounces;* Distilled Water *five fluidounces.* Liquefy the Honey by heat, and mix with it the Acetic Acid and Water." *Br.*

This mixture of honey and vinegar forms a pleasant addition to gargles, and is sometimes used as a vehicle of expectorant medicines, and to impart flavour to drinks in febrile complaints.* W.

* *Oxymel of Squill. Oxymel Scillæ.* There may be some, who notwithstanding the omission of this preparation by the Pharmacopœias, may still continue to prescribe it, and the pharmaceutist should be prepared to fulfil their prescription. We therefore retain, in the form of a note, what was formerly said in the text in reference to this oxymel. The following was the U. S. formula of 1850.

"Take of Vinegar of Squill *two pints;* Clarified Honey *a pint and a half.* Mix them, and evaporate by means of a water-bath to the proper consistence. The specific gravity of the Oxymel of Squill should be 1·32."

This preparation has the virtues of squill, but is in no respect superior to the syrup.

MISTURÆ.

Mixtures.

This term should be restricted, in the language of pharmacy, to those preparations in which insoluble substances, whether solid or liquid, are suspended in watery fluids, by the intervention of gum arabic, sugar, the yolk of eggs, or other viscid matter. When the suspended substance is of an oleaginous nature, the mixture is sometimes called an *emulsion*. The object of these preparations is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines; and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of a uniform and perfect mixture. As a general rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the intermedium, before the watery vehicle is added. In the case of the liquid balsams and oils, if gum arabic be employed as the intermedium, it should be previously brought to the state of mucilage of the consistence directed in the U. S. Pharmacopœia.* The white of eggs has been frequently ordered by physicians as the suspending substance; but it is inferior for this purpose to the yolk, or to gum arabic. When the white is used it should be well beaten, and incorporated with the oleaginous or balsamic substances before the water is added. Mixtures are generally the objects of extemporaneous prescription; but a few have been deemed of sufficient importance to merit a place in the Pharmacopœias. They should be prepared only when wanted for use. The Mixtures, formerly officinal, which have been discarded in the recent revision of the Br. Pharmacopœia, are *Mistura Acaciæ*, Ed., *Mistura Althææ*, Ed., *Mistura Camphoræ cum Magnesia*, Ed., *Mistura Ferri Aromatica*, Dub., *Mistura Gentianæ Composita*, Lond., and *Mistura Spiritûs Vini Gallici*, Lond.

W.

MISTURA AMMONIACI. *U. S., Br. Mixture of Ammoniac.*

"Take of Ammoniac *one hundred and twenty grains;* Water *half a pint.* Rub the Ammoniac with the Water, gradually added, until they are thoroughly mixed, and strain." *U. S.*

"Take of Ammoniac, in coarse powder, *a quarter of an ounce* [avoirdupois]; Distilled Water *eight fluidounces.* Triturate the Ammoniac with the Water, gradually added, until the mixture assumes a milky appearance, then strain through muslin." *Br.*

In this mixture the insoluble part of the ammoniac is suspended by means of the gum, imparting a milky appearance to the preparation, which, from this circumstance, was formerly called *lac ammoniaci* or *milk of ammoniac*. The greater portion of the resin subsides upon standing. The mixture is slightly curdled by acids. The dose is from one to two tablespoonfuls.

W.

MISTURA AMYGDALÆ. *U. S. Mixture of Almond. Almond Emulsion.*

"Take of Sweet Almond *half a troyounce;* Gum Arabic, in fine powder,

It is chiefly used as an expectorant in chronic catarrh, humoral asthma, hooping-cough, and generally in those states of the pulmonary organs in which the bronchial tubes are loaded with a viscid mucus of difficult expectoration. The dose is from one to two fluidrachms. In large doses it is emetic, and as such may sometimes be given with advantage in infantile croup and catarrh.

* The proportion of gum and water necessary to make a good emulsion with the fixed oils varies with the oil. Thus, while castor oil requires only two drachms of the gum and three drachms of water to the ounce, most other fixed oils require half their weight of gum, and a weight of water equal to half that of the oil and gum united. These quantities being well rubbed together, any desirable amount of water may afterwards be gradually added, and will readily incorporate with the other ingredients. (Overbeck, *Pharm. Cent. Blatt*, A. D. 1851, p. 95.)

thirty grains; Sugar *one hundred and twenty grains;* Distilled Water *eight fluidounces.* Having blanched the Almond, beat it with the Gum Arabic and Sugar, in a mortar, until they are thoroughly mixed; then rub the mixture with the Distilled Water gradually added, and strain." *U. S.*

"Take of Compound Powder of Almonds *two ounces and a half* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Rub the Powder with a little of the Water into a thin paste, then add the remainder of the Water, and strain through muslin." *Br.*

These preparations are essentially the same; the gum and sugar, which enter into the U. S. formula directly, being ingredients of the compound powder of almonds of the British. The processes are both preferable to that of the old London Pharmacopœia, in which a confection of almonds was employed; as this preparation was liable to spoil quickly when kept. The gum arabic in these formulas is introduced, not so much for its demulcent properties, as to assist in the suspension of the insoluble ingredients of the almonds. The same formula will answer for the preparation of an *emulsion of bitter almonds,* which may be preferred to the present when a slight influence of hydrocyanic acid is desired.

The oleaginous matter of the almonds is suspended in the water by means of their albumen, gum, and sugar, forming a milky emulsion. When the almonds themselves are employed, as in the U. S. process, care should be taken to reduce them to the consistence of a paste previously to the addition of the water; and with each successive portion of fluid a uniform mixture should be formed before another portion is added. Common water, when not very impure, may be properly substituted for the distilled. Great care should be taken to select the almonds perfectly free from rancidity. The mixture is not permanent. Upon standing, the oil rises like thick cream to the surface, and the separation is effected more quickly by heat, alcohol, and the acids, which coagulate the albumen. The preparation is closely analogous to milk in chemical relations and appearance. In warm weather it soon becomes sour, and unfit for use.

The almond mixture has a bland taste, and may be used as an agreeable, nutritive demulcent in catarrhal and dysenteric affections, and irritation of the urinary passages. To be of service it must be freely employed. From two to eight fluidounces may be taken at once. It is occasionally employed as the vehicle of less agreeable medicines; but should not be used in connection with any considerable quantity of tinctures, acidulous salts, or other substances containing an excess of acid. W.

MISTURA ASSAFŒTIDÆ. *U. S. Assafetida Mixture.*

"Take of Assafetida *one hundred and twenty grains;* Water *half a pint.* Rub the Assafetida with the Water, gradually added, until they are thoroughly mixed." *U. S.*

This mixture, from its whiteness and opacity, is frequently called *lac assafœtidæ* or *milk of assafetida.* It is, as a general rule, the best form for the administration of this antispasmodic, being less stimulant than the tincture, and more prompt in its action than the pill. Its excessively disagreeable smell and taste are, however, objections, which induce a frequent preference of the last-mentioned preparation. It is very often employed as an enema. The dose is from one to two tablespoonfuls frequently repeated. From two to four fluidounces may be given by the rectum.* W.

* *Syrup of Assafetida.* Such a preparation has been proposed by Mr. Richard Peltz. He has found the following formula to answer the purpose best. Take of assafetida ℥j, boiling water Oj, sugar lbij. Rub the assafetida with a part of the water so as to make a uniform paste, then gradually add the remainder of the water, strain, and add the sugar, heating moderately till it is dissolved. This has a less disagreeable taste than the mixture, and keeps much better, remaining several months without change, while the latter is often altered in a short time. The dose is the same as that of the mixture. (*Am. Journ. of Pharm.,* xxiv. 313.)—*Note to the tenth edition.*

MISTURA CHLOROFORMI. *U.S. Mixture of Chloroform.*

"Take of Purified Chloroform *half a troyounce;* Camphor *sixty grains;* the yolk of *one* Egg; Water *six fluidounces.* Rub the yolk in a mortar, first by itself, then with the Camphor, previously dissolved in the Chloroform, and lastly, with the Water, gradually added, so as to make a uniform mixture." *U. S.*

In consequence of the great facility with which camphor dissolves in chloroform, and the ready miscibility of the solution, by the intervention of the yolk of eggs, with water, this mixture affords an easy and agreeable method of administering these medicines jointly. Besides, in consequence of the preservative influence of the chloroform, it will keep long unchanged. The dose is one or two tablespoonfuls.

MISTURA CREASOTI. *Br. Creasote Mixture.*

"Take of Creasote *sixteen minims;* Glacial Acetic Acid *sixteen minims;* Spirit of Juniper *half a fluidrachm;* Syrup *one fluidounce;* Distilled Water *fifteen fluidounces.* Mix the Creasote with the Acetic Acid, gradually add the Water, and lastly the Syrup and Spirit of Juniper." *Br.*

The dose of this mixture is a fluidounce, containing a minim of Creasote. W.

MISTURA CRETÆ. *U.S., Br. Chalk Mixture.*

"Take of Prepared Chalk *half a troyounce;* Sugar [refined], Gum Arabic, in fine powder, each, *one hundred and twenty grains;* Cinnamon Water, Water, each, *four fluidounces.* Rub them together until they are thoroughly mixed." *U. S.*

"Take of Prepared Chalk *a quarter of an ounce* [avoirdupois]; Gum Arabic, in powder, *a quarter of an ounce* [avoird.]; Syrup *half a fluidounce;* Cinnamon Water *seven fluidounces and a half.* Triturate the Chalk and Gum Arabic with the Cinnamon Water, then add the Syrup, and mix." *Br.*

This mixture is a convenient form for administering chalk, and is much employed in looseness of the bowels accompanied with acidity. Laudanum and kino or catechu are very often added to increase its astringency. The dose is a tablespoonful frequently repeated. W.

MISTURA FERRI COMPOSITA. *U.S., Br. Compound Mixture of Iron.*

"Take of Myrrh, Sugar [refined], each, *sixty grains;* Carbonate of Potassa *twenty-five grains;* Sulphate of Iron, in coarse powder, *twenty grains;* Spirit of Lavender *half a fluidounce;* Rose Water *seven fluidounces and a half.* Rub the Myrrh, Sugar, and Carbonate of Potassa with the Rose Water, gradually added, then with the Spirit of Lavender, and, lastly, with the Sulphate of Iron; and pour the mixture immediately into a bottle, which must be well stopped." *U. S.*

"Take of Sulphate of Iron *thirty grains;* Carbonate of Potash *twenty-five grains;* Myrrh, in powder, Sugar, each, *sixty grains;* Spirit of Nutmeg *one fluidrachm;* Rose Water *eight fluidounces.* Triturate the Myrrh and Carbonate of Potash with the Sugar, the Spirit of Nutmeg, and seven [fluid]ounces of the Rose Water, the latter being gradually added, until a uniform mixture is obtained. To this add the Sulphate of Iron, previously dissolved in the remaining [fluid]ounce of Rose Water, and enclose the mixture at once in a bottle which should be tightly corked." *Br.*

Wine of Assafetida. Mr. H. N. Rittenhouse proposes a concentrated wine of assafetida, as affording an easy method of preparing the mixture, which, when called for in haste, cannot always be furnished in due time, from the amount of trituration required. He rubs half an ounce of the gum-resin with ten fluidrachms of white wine until the former is suspended. Two ounces of the wine are thus obtained; and, as each drachm contains fifteen grains of assafetida, it is easy to prepare the mixture of the officinal strength, by simply mixing the wine in due proportion with water. (*Am. Journ. of Pharm.*, xxvii. 216.)—*Note to the eleventh edition.*

This is very nearly the same with the celebrated tonic or antihectic myrrh mixture of Dr. Griffith. The sulphate of iron is decomposed by the carbonate of potassa, with the production of sulphate of potassa and carbonate of protoxide of iron; while the excess of the alkaline carbonate forms a saponaceous compound with the myrrh. The mixture is at first of a greenish colour, which it loses upon exposure to the air, in consequence of the conversion of the protoxide of iron of the carbonate into the red or sesquioxide. It may, however, be kept for some time without change, if the vessel in which it is contained be well closed; but the best plan is to prepare it only when wanted for use. The sugar contained in it contributes somewhat to retard the further oxidation of the protoxide of iron, and, if considerably increased in amount, would act still more efficiently. The finest pieces of myrrh in lump should be selected, and rubbed down for the occasion with a little of the rose water; as the powdered myrrh of the shops is often impure, and does not make a good mixture.

This mixture is a good tonic in debility of the digestive organs, especially when attended with derangement of the menstrual function. Hence it is used with advantage in chlorosis and hysterical affections. It has been also much employed in the hectic fever of phthisis and chronic catarrh. It is contraindicated by the existence of inflammation of the gastric mucous membrane. The dose is one or two fluidounces two or three times a day. W.

MISTURA GLYCYRRHIZÆ COMPOSITA. *U. S. Compound Mixture of Liquorice. Brown Mixture.*

"Take of Liquorice [extract], in fine powder, Sugar, in coarse powder, Gum Arabic, in fine powder, each, *half a troyounce;* Camphorated Tincture of Opium *two fluidounces;* Wine of Antimony *a fluidounce;* Spirit of Nitrous Ether *half a fluidounce;* Water *twelve fluidounces.* Rub the Liquorice, Sugar, and Gum Arabic with the Water, gradually added; then add the other ingredients, and mix the whole together." *U. S.*

This is an exceedingly popular cough mixture, which was made officinal in the U. S. Pharmacopœia of 1850. The spirit of nitrous ether is probably useful by somewhat retarding decomposition. The preparation is applicable to the advanced stages of catarrhal affections, after expectoration has become established. The dose is a tablespoonful for an adult; a teaspoonful for a child two years old. It should be well shaken when administered. W.

MISTURA GUAIACI. *Br. Guaiac Mixture.*

"Take of Guaiac Resin, in powder, *half an ounce* [avoirdupois]; Sugar *half an ounce* [avoird.]; Gum Arabic, powdered, *a quarter of an ounce* [avoird.]; Cinnamon Water *one pint* [Imperial measure]. Triturate the Guaiac with the Sugar and the Gum, adding gradually the Cinnamon Water." *Br.*

For the changes of colour which the guaiac in this mixture undergoes, and produces in other substances, see *Guaiaci Resina*, p. 429. From one to three tablespoonfuls may be given for a dose, and repeated two or three times a day, or more frequently. W.

MISTURA POTASSÆ CITRATIS. *U. S.* LIQUOR POTASSÆ CITRATIS. *U. S.* 1850. *Mixture of Citrate of Potassa. Neutral Mixture.*

"Take of Lemon Juice, fresh, *half a pint;* Bicarbonate of Potassa *a sufficient quantity.* Add the Bicarbonate gradually to the Lemon Juice until the acid is completely saturated; then strain through muslin." *U. S.*

For remarks on this preparation, see *Liquor Potassæ Citratis*, page 1207. The dose is a tablespoonful or half a fluidounce, which, when taken, may be somewhat diluted with water. W.

MISTURA SCAMMONII. *Br. Scammony Mixture.*

"Take of Resin of Scammony *four grains;* Milk *two* [*fluid*]*ounces.* Tri

turate the Resin of Scammony with a little of the Milk, and continue the trituration, gradually adding the remainder of the Milk, until a uniform emulsion is obtained." *Br.*

This officinal is an imitation of a mixture recommended by Planche. The resin of scammony mixes admirably with the vehicle, and forms an emulsion scarcely distinguishable in appearance or taste from rich milk. Of course, it should be prepared only when wanted for immediate use. The whole is to be taken for a dose. W.

MORPHIA.

Preparations of Morphia.

MORPHIA. *U. S. Morphia.*

"Take of Opium, sliced, *twelve troyounces;* Water of Ammonia *six fluidounces;* Animal Charcoal, in fine powder, Alcohol, Distilled Water, each, *a sufficient quantity.* Macerate the Opium with four pints of Distilled Water for twenty-four hours, and, having worked it with the hand, again macerate for twenty-four hours, and strain. In like manner, macerate the residue twice successively with the same quantity of Distilled Water, and strain. Mix the infusions, evaporate to six pints, and filter; then add five pints of Alcohol, and afterwards three fluidounces of the Water of Ammonia, previously mixed with half a pint of Alcohol. After twenty-four hours, pour in the remainder of the Water of Ammonia, mixed, as before, with half a pint of Alcohol; and set the liquid aside for twenty-four hours that crystals may form. To purify these, boil them with two pints of Alcohol until they are dissolved, filter the solution, while hot, through Animal Charcoal, and set it aside to crystallize." *U. S.*

This process will be better understood by a previous acquaintance with the properties and chemical relations of the substance in question.

Morphia crystallizes from alcohol in the form of small, colourless, shining crystals. It is inodorous and bitter. Exposed to a moderate heat, it loses its water of crystallization and the crystalline form, becoming white and opaque. At a higher temperature it melts, forming a yellowish liquid, which becomes white and crystalline upon cooling. Heated in the open air, it burns with a bright flame, and at a red heat is wholly dissipated. In the products resulting from the combustion of opium or morphia, this alkaloid may be detected, proving that it is partly volatilized, when burned. (Descharmes, *Arch. Gén.*, Fév. 1855, p. 240.) It is insoluble or nearly so in cold water, soluble in rather less than 100 parts of water at 212°, slightly soluble in cold alcohol, and freely so in boiling alcohol, which deposits it upon cooling. It is dissolved also by the fixed and volatile oils, but very slightly if at all by ether. Both morphia and its salts are insoluble in chloroform. (Lepage, *Journ. de Pharm.*, xxv. 258.) Morphia in solution is to a considerable extent absorbed by animal charcoal, which, though it will part with most of the alkaloid to alcohol, cannot be wholly deprived of it by repeated washings with that liquid, whether cold or hot. (Lefort, *Journ. de Pharm.*, Août, 1861, p. 98.) Its solution restores the blue colour of litmus paper reddened by acids, and turns the yellow of turmeric to brown. With the acids it forms salts, which are generally soluble, and are decomposed by the alkalies. The solutions of potassa and soda also dissolve morphia, which is precipitated slowly from them on exposure to the air, in consequence of the absorption of carbonic acid. Solution of ammonia has to a certain extent the same solvent power; and hence the necessity, in precipitating morphia by this alkali, not to employ it in great excess. Solution of iodine with iodide of potassium precipitates the salts of morphia in aqueous solution. With chlorine water morphia and its salts assume an orange colour, and the same effect is produced on them by solution of chlorinated soda. (Fairthorne, *Am. Journ. of Pharm.*, xxviii. 9.) By the contact of nitric acid, they assume a blood-red colour, which

ultimately changes to yellow; and this is one of the tests of morphia; but, as the same change of colour is produced with brucia and impure strychnia, it cannot be relied on in the absence of other evidence. When added to a solution of iodic acid, or an acidulous iodate, morphia and its salts redden the liquid and set iodine free. (*Serullas.*) This is a very delicate test, but is not conclusive, as various other organic substances act in a similar manner. M. J. Lefort, however, has found that the colour produced by these substances is removed by ammonia, while the redness produced with morphia is greatly intensified by the addition of that alkali. This test, thus modified by the addition of ammonia, is so delicate that, according to M. Lefort, it will detect one part of morphia in 10,000 parts of a liquid holding it in solution. (*Journ. de Pharm.*, Août, 1861, p. 113.)* Morphia and its salts assume a fine blue colour with the sesquichloride of iron, and the salts of the sesquioxide; at least this is true of the alkaloid, its sulphate, acetate, and oxalate; and the same effect will be produced by the other salts, if previously decomposed by an alkali; but that this test should be satisfactory, it is necessary to operate on morphia either in powder or concentrated solution. (*Lefort.*) Water, acids, and alkalies, added in large quantity to the blue compound formed, destroy its colour. According to Pelletier, moreover, there occasionally exists in opium a principle called by him pseudomorphia, which becomes red under the action of nitric acid, and changes the salts of sesquioxide of iron blue, and yet is destitute of poisonous properties; so that the occurrence of these phenomena, in any medico-legal case, cannot be considered as certain evidence of the presence of morphia. (See *Am. Journ. of Pharm.*, viii. 77.) The terchloride of gold precipitates morphia first yellow, then bluish, and lastly violet. (*Larocque* and *Thibierge.*) Peroxide of copper and oxide of silver are precipitated by morphia from their ammoniacal solutions, and ferridcyanide of potassium in solution is reduced by it to the ferrocyanide. (*Chem. Gaz.*, No. 367, p. 54.) A solution of acetate or sulphate of morphia, containing only one part of the salt in 100, precipitates silver from a solution of the nitrate of that metal. (*Horsley.*) Morphia is precipitated from its solutions by potassa or soda, and redissolved by an excess of the alkali. Infusions of galls and other vegetable substances containing tannic acid precipitate morphia in the state of a tannate, which is soluble in acetic acid; but, according to Dublanc, the alkali is not precipitated by pure

* When a mixture of a little morphia and *iodic acid* with a few drops of water is gently heated in a capsule, a series of explosions is produced, with the evolution of gas. The same thing happens with other vegetable alkaloids treated in the same manner; and Dr. Brett proposes this reaction of iodic acid, which takes place with no other organic substance that he has tried, as a test of the alkaloids. (*Pharm. Journ.*, xvi. 211.)

Unsized Paper in testing for Morphia. Most of the tests of morphia will act more satisfactorily if the alkaloid or its salts be fixed in unsized paper, which will then exhibit the characteristic changes of colour when exposed to the agents employed. Paper may be prepared for this purpose by dipping slips of perfectly white filtering paper several times in the liquid to be examined, and, after each immersion, drying the paper by a moderate heat. (Lefort, *Journ. de Pharm.*, Août, 1861, p. 106.)—*Note to the twelfth edition.*

Stas's method of extracting the Alkaloids from Mixtures. To separate the alkaloid from foreign matters, the mixture is treated alternately with water and alcohol in different degrees of concentration; the liquors thus obtained are filtered; tartaric or oxalic acid, but preferably the former, is added in excess; the mixture is heated to 160° or 170° F.; the whole is placed upon a filter; the deposited matter is washed with concentrated alcohol; the alcoholic solution is evaporated at a temperature not exceeding 95° F.; the residue is introduced into a small bottle; a solution of caustic potassa or soda is added, little by little, and afterwards four or five times the measure of ether; the mixture is shaken and then allowed to stand; and, finally, the ether is decanted, and yields the alkaloid by spontaneous evaporation. Stas included morphia among the alkaloids thus separable, though known to be nearly insoluble in ether; but Lefort has shown that the process is not applicable to that alkaloid. (*Journ. de Pharm.*, Août, 1861, p. 99.) M. Alfred Valser, however, has ascertained that, if acetic ether be substituted for ether, the process is equally applicable to morphia. (See *Am. Journ. of Pharm.*, Sept. 1864, p. 439.)—*Note to the twelfth edition.*

gallic acid If ammonia be added to a mixture of the solutions of chlorine and morphia, a dark-brown colour is produced, which is destroyed by a further addition of chlorine. The proportion of the constituents of morphia is somewhat differently given by different writers. According to the most recent authorities, anhydrous morphia consists of thirty-four eqs. of carbon 204, nineteen of hydrogen 19, one of nitrogen 14, and six of oxygen 48 = 285, to which in the crystals are added two eqs. of water 18, or about 5·8 per cent. ($C_{34}H_{19}NO_6.2HO$).

Various processes for preparing morphia have been employed. In most of them the morphia is extracted from opium by maceration with water either pure or acidulated, is then precipitated by ammonia, and afterwards purified by the agency of alcohol, or by repeated solution in a dilute acid and precipitation.

Sertürner, the discoverer of morphia, made an infusion of opium in distilled water, precipitated the morphia by ammonia in excess, dissolved the precipitate in dilute sulphuric acid, precipitated anew by ammonia, and purified by solution in boiling alcohol, and crystallization.

The process of the French Codex is a modification of that of Sertürner. It is as follows. "Take of opium 1000 parts, solution of ammonia a sufficient quantity. Exhaust the opium, by means of cold water, of all its parts soluble in that menstruum. For that purpose, it is sufficient to treat the opium, four times consecutively, with ten parts of water to one of the drug, provided care be taken to macerate the opium for some hours, and to work it with the hands. Filter the liquors, and evaporate them to a quarter of their volume. Then add sufficient ammonia to render the liquor very sensibly alkaline. Boil for some minutes, always maintaining a slight excess of ammonia. Upon cooling, the morphia, impure and much coloured, will be precipitated in granular crystals, which are to be washed with cold water. Reduce this coloured morphia to powder, macerate it for twelve hours in alcohol of 24° Cartier [sp. gr. about 0·900]; then decant the alcoholic liquid; dissolve the residuary morphia, already in great measure deprived of colour by the cold alcohol, in boiling alcohol of 33° Cartier [sp. gr. about 0·850]; add to the solution a little animal charcoal and filter. Upon cooling, the morphia crystallizes in colourless needles. In this state the morphia always retains some narcotina, to free it from which, boil it with sulphuric ether in a matrass with a long neck surmounted by a refrigerator."

The process of the U. S. Pharmacopœia is an improvement upon the above, and is essentially the same as that of Dr. Edward Staples, published in the *Journal of the Philadelphia College of Pharmacy* (i. 15). Without repeating a description of the process, we shall make such remarks upon its several steps, as appear to us likely to be of practical advantage. The employment of water as the solvent is justified by the almost universal practice. It is true that dilute acetic acid has sometimes been employed, and Vogel states that the product thus obtained is much greater than when water alone is used. But, when the opium is properly comminuted, either by being reduced to a coarse powder when dry, or by being finely sliced in its ordinary state, water alone will be found sufficiently to extract the morphia, by a protracted maceration or digestion in successive portions of water, assisted by kneading, as directed in the Pharmacopœia. The acids have this disadvantage, that they dissolve more of the narcotina than pure water, and thus render the ultimate product more impure; for the narcotina which is originally taken up continues associated with the morphia in all the subsequent steps of the process. It has been proposed to expose the opium to fermentation with water and yeast, in order to facilitate the extraction of the morphia. By this plan M. Blondeau succeeded in procuring more of the alkaline principle than he could obtain by the ordinary mode; and his results were confirmed by the experiments of MM. Robiquet and Guibourt. According to these latter chemists, no alcohol is produced during the fermentation, which appears to act merely by disengaging the morphia from the combinations in

which it naturally exists, and which tend to counteract the solvent power of the menstruum. Alcohol was proposed as the solvent by M. Guillermond, but is liable to the objection that it dissolves also the resin, a portion of which is afterwards precipitated with the morphia, and embarrasses the process. Much of the resin, however, may be separated by distilling most of the alcohol from the tincture, and then adding water. The resin is precipitated, and the liquor may now be treated in the same manner as the aqueous infusion.* On the whole, however, the officinal mode of extraction will probably be found most satisfactory; and Mohr states that opium thus exhausted yields no more morphia even to muriatic acid; but he recommends that each maceration should be followed by strong expression. The infusion of opium having been prepared, the next object is to decompose the meconate or other salt of morphia contained in it. For this purpose solution of ammonia is added, which seizes the acid, and precipitates the organic alkali; but much colouring matter is thrown down along with the latter, occasioning some trouble to separate it, unless measures are taken to obviate this effect. The object is gained by mixing the infusion with alcohol, previously to the addition of the ammonia, and by employing the solution of ammonia itself in connection with alcohol, as directed in the Pharmacopœia. This is the peculiarity and chief merit of the process of Dr. Staples. By the presence of the alcohol in all parts of the liquor, the colouring matter is dissolved as soon as it is separated by the ammonia, and the morphia is thus precipitated in a much purer state. The advantage of adding the ammonia in separate portions is, that the morphia, being thus more slowly disengaged, can be more completely deprived of its impurities by the alcohol of the mixture, than if the whole were liberated at once. It is necessary to be careful that the ammonia be not in great excess; as it has the property, under these circumstances, of dissolving the morphia in some degree, and will therefore lessen the product, while waste is incurred by its own unnecessary consumption. Very little more should be added than is sufficient to saturate the acid present. The solution of ammonia of the shops is often much below the officinal standard, and this should always be attended to in the process. Alcohol is mixed with the ammonia before it is added, in order that every particle of the separated morphia may come in contact with the particles of this fluid, and thus have the opportunity of being deprived of colouring matter. The crystals of morphia obtained by this first operation have a light-yellowish colour, and are much purer than when no alcohol is added to the infusion before the precipitation by ammonia. According to Dr. Staples, opium yields from 10 to 12·5 per cent. of the crystals. Their purification by solution in boiling alcohol is the concluding step of the operation. The liquid, on cooling, deposits the morphia crystallized, and nearly free from colour. As cold alcohol retains a portion of morphia, it should not be employed too largely. Alcohol somewhat reduced by water is preferable to highly rectified spirit; as it is less capable of holding the morphia in solution when cold. It is sufficiently strong at 25° Baumé (sp. gr. 0·9032). The impure morphia remaining in the alcohol may be obtained by distilling off the latter, and, when sufficiently accumulated, may be purified by a separate operation. The crystals of morphia may

* By a modification of the process of Guillermond, MM. Desmedt have succeeded in extracting all the morphia from opium, perfectly free from narcotina. Of crude opium 60 parts were treated with 240 of alcohol at 71° centigrade (160° F.), and expressed when cold; the residue was then treated in the same manner with 160 parts of alcohol; the liquor was introduced into a bottle well stopped; next day a copious crystallization of narcotina appeared, without the least morphia; the liquid was decanted, and, on the addition of 4 parts of ammonia, furnished a considerable quantity of morphia, free from narcotina. To the mother-liquor a little distilled water was added, and the mixture was kept at the temperature of 24° C. In two days an additional quantity of the crystals of morphia was obtained equally free from narcotina. The opium was completely exhausted, and the 60 parts employed furnished 5 parts of morphia. (*Annuaire de Thérap.*, 1852, p. 31.)—*Note to the tenth edition.*

also be purified by solution in dilute sulphuric acid, digestion with purified animal charcoal, filtration, and precipitation by ammonia. If alcohol he added to the solution previously to the ammonia, the digestion with animal charcoal may be dispensed with, as the alcohol retains the colouring matter. Morphia procured in this way always contains narcotina, from which it may be freed by ether, or in some of the modes hereafter to be indicated.

Magnesia was employed by Robiquet instead of ammonia. But his process was soon abandoned; as it was found to occupy more time, to require a greater consumption of alcohol, and to be attended with a greater loss of morphia in consequence of the previous washing, than the processes in which ammonia was employed as the precipitant. For an account of it the reader is referred to former editions of this work.

A process for extracting morphia without the employment of alcohol was devised by MM. Henry, jun., and Plisson. The opium was exhausted by water acidulated with muriatic acid; the resulting solution was sufficiently concentrated, then filtered, and decomposed by ammonia; the precipitate was washed and treated with muriatic acid to saturation; and the muriatic solution was boiled with animal charcoal, filtered, and evaporated to the point of crystallization. The crystals of muriate of morphia thus obtained were pressed, purified by repeated solution and crystallization, and finally decomposed by ammonia. (*Journ. de Chim. Méd.*, Mars, 1828.)

Somewhat similar to this is the process of Gregory, of Edinburgh, by which muriate of morphia is obtained by double decomposition between chloride of calcium and the meconate of morphia of the opium, and the muriate thus obtained is decomposed by ammonia. This process was adopted by the Ed. College for the preparation of muriate of morphia; and is retained in the present Br. Pharmacopœia. It will be sufficiently explained under *Muriate of Morphia.*

Mohr has proposed a process founded on the solubility of morphia in water mixed with lime, which he recommends as the shortest and easiest method of procuring the alkaloid, without the use of alcohol, and without the possibility of contamination from narcotina. Opium is three or four times successively macerated with three parts of water, and each time strongly expressed. The liquors are then added to a boiling-hot milk of lime, containing a quantity of lime equal to about a sixth or a quarter of the opium used; and the mixture is boiled for a few minutes. It is then strained through linen, and the residue washed with boiling water and expressed. The whole of the narcotina is left behind, as not a trace of it can be discovered in the filtered liquor. The liquor thus obtained is evaporated till reduced to double the weight of the opium, then quickly filtered through paper, and heated to ebullition. Muriate of ammonia is now added to it in the proportion of 1 part to 16 of the opium used; and the morphia is abundantly precipitated. The use of animal charcoal is unnecessary in the process, as the lime acts even more powerfully as a decolorizing agent. The crystallized morphia obtained is somewhat coloured, but may be rendered pure by solution in dilute muriatic acid, boiling with milk of lime, filtration, and precipitation by muriate of ammonia. (*Annal. der Pharm.*, xxxv. 119.)

Various other processes, or modifications of those above described, have been proposed; but, for the preparation of small quantities of morphia by the apothecary, none are probably better adapted than that of the U. S. Pharmacopœia.

It has been already stated that morphia, obtained in the ordinary manner, contains a considerable proportion of narcotina. It is highly probable that this ingredient exercises no influence, either beneficial or injurious, upon the operation of the morphia; but, as the contrary has been supposed, various methods have been employed for separating it. The simplest and easiest is to submit the mixture to the action of ether, which dissolves the narcotina and leaves the morphia. The agency of acetic acid may also be resorted to. Distilled vinegar, or

diluted acetic acid of the same strength, will dissolve the morphia and leave the narcotina, and the former may be recovered from the acetic solution by saturating the acid with ammonia. Another mode is to dissolve the mixed bases in strong acetic acid (of 7° Baumé, or sp. gr. 1·0511, for example), and expose the solution to heat. The narcotina is deposited, and the morphia, remaining in solution, may be precipitated by diluting the liquid and adding ammonia. (*Journ. de Pharm.*, xvii. 640.) Wittstock advises one of the following modes. Dissolve the impure morphia in dilute muriatic acid, evaporate to the point of crystallization, and strongly express the crystals, which consist solely of the muriate of morphia, the narcotina being retained in the mother-waters:—or saturate the muriatic solution with common salt, which will render the liquor milky, and cause the narcotina to separate after some days; then precipitate the morphia by ammonia:—or pour into the diluted muriatic solution a weak ley of caustic potassa, which, if in slight excess, will dissolve the morphia at the moment of its separation, while the narcotina is precipitated; then immediately filter the liquor, and separate the morphia by neutralizing the alkali. If the potassa is in great excess, a little of the narcotina is redissolved. (Berzelius, *Traité de Chim.*) Mohr recommends to dissolve the morphia in dilute muriatic acid, and to boil the solution with lime, which throws down the narcotina and holds the morphia dissolved. The liquid being filtered yields the morphia upon the addition of muriate of ammonia. (*Annal. der Pharm.*, xxv. 123.)

The proportion of pure morphia which Turkey opium is capable of affording varies from 9 per cent. or less to 14 per cent., according to the quality of the drug; but much less than the least quantity mentioned is often obtained, in consequence of the incomplete exhaustion of the opium, the loss in the process for preparing it, or inferiority in the quality of the drug.

Medical Properties. There can be no doubt that morphia is the chief narcotic principle of opium, from which, however, it differs somewhat in its mode of action. Whether the difference arises from the peculiar state of combination in which morphia exists in opium, or from other narcotic principles being associated with it, is somewhat uncertain; but the former would seem to be in part the cause, from the circumstance that, long before the discovery of this alkaloid, preparations of opium were habitually used, in which the properties of the medicine were somewhat similarly modified by the agency of vinegar, lemon-juice, or other vegetable acid. In consequence of its insolubility in water, morphia in its pure state is less certain in its effects than some of its saline compounds; as the mode and degree of its action must, in some measure, depend on the presence or absence of acid in the stomach, and perhaps on the peculiar character of the acid. Its salts are therefore always preferred. The acetate, sulphate, and muriate have been employed. Between these there is a great similarity of action, and what may be said of one, in regard to its therapeutical effects, will equally apply to the others. They have the anodyne, soporific, and diaphoretic properties of opium, but are less stimulant, less disposed to constipate the bowels, and less apt to leave behind them headache, nausea, or other unpleasant effect. They are usually also more acceptable to an irritated stomach, and may be retained, when opium or its tincture would be rejected. That they operate by entering the circulation is proved by the detection of morphia in the urine, though it is said not to be eliminated by the skin. (*Lefort.*) They are applicable to all cases where the object is to relieve pain, quiet restlessness, promote sleep, or allay nervous irritation in any shape; but are less efficient than opium in the suppression of morbid discharges, and as stimulants in low forms of disease. A great advantage which they possess is the convenience of their external application to blistered surfaces, and the certainty of their effects when thus applied. In cases which do not admit of the internal use of opium or its preparations, the acetate or sulphate of morphia, sprinkled, in triple the ordinary dose, upon a blistered surface denuded

of the cuticle, will be found to exercise upon the system all the influence it is capable of exerting when taken into the stomach. Applied in this manner, these salts are peculiarly useful in relieving violent neuralgic pains, and controlling obstinate sickness of the stomach. When intended to act on the system through the medium of the skin, they should be applied preferably to the epigastrium; when to act locally, as near the affected part as possible. Solutions of the salts of morphia also sometimes operate very favourably, both generally and locally, when injected, by means of a sharp-pointed syringe, adapted to the purpose, into the areolar tissue beneath the skin. Given in doses nearly, but not quite sufficient to produce sleep, they sometimes occasion a very troublesome condition of the brain, amounting almost to delirium; but this always subsides spontaneously, or vanishes immediately upon the increase of the dose. An embrocation for external use may be made by dissolving muriate or acetate of morphia in glycerin, which takes up about 5 per cent. of these salts at common temperatures, and more with the aid of heat. (*Journ. de Pharm.*, xxvi. 90.) Oleic acid has also been proposed as a vehicle for morphia externally used, as it dissolves both the alkaloid and its salts perfectly in considerable proportion. A liniment has been proposed, consisting of 300 parts of oleic acid and 1 of morphia, scented with a little oil of bergamot. (*Ibid.*, xxvi. 302.)

In overdoses, morphia and its salts produce the effects of narcotic poisons, though not perhaps equally with a quantity of opium equivalent in anodyne effect. An instance of death from the injection of three grains of morphia into the rectum is recorded by Dr. Anstie, of England, but the age of the patient is not mentioned. (*Med. Times and Gaz.*, Dec. 1862, p. 317.) The toxicological treatment is precisely the same as in the case of laudanum. (See *Opium.*) Strong coffee has been employed with great apparent advantage as an antidote.

As the proportion of acid necessary to neutralize morphia is very small, the dose of the alkaloid is the same as that of its salts. One-sixth of a grain may be considered about equivalent to a grain of opium of the medium strength.

Off. Prep. Morphiæ Acetas, *U. S.;* Morphiæ Murias, *U. S.;* Morphiæ Sulphas, *U. S.* W.

MORPHIÆ ACETAS. *U. S. Acetate of Morphia.*

"Take of Morphia, in fine powder, freed from narcotina by the action of Ether, *a troyounce;* Distilled Water *half a pint;* Acetic Acid *a sufficient quantity.* Mix the Morphia with the Distilled Water; then carefully drop in Acetic Acid, constantly stirring, until the Morphia is saturated and dissolved. Evaporate the solution, by means of a water-bath, to the consistence of syrup. Lastly, dry the salt with a gentle heat, and rub it into powder." *U. S.*

In this process, morphia is saturated with acetic acid, which is employed in preference to vinegar for saturating the alkaloid, because it can leave no impurity in the resulting salt. The solution of the morphia in the water is an indication that it is saturated. A small excess of acid is attended with no inconvenience, as it is subsequently driven off by the heat. Care is required not to employ too much heat in the evaporation; as the acetate is easily decomposed, a portion of the acetic acid escaping, and leaving an equivalent portion of uncombined morphia. With attention to arrest the evaporation at a certain point, the acetate may be obtained in the state of crystals; but the crystallization is attended with some difficulty, and evaporation to dryness is almost universally preferred. Some recommend to dissolve the morphia in boiling alcohol, instead of suspending it in water, previously to the addition of the acetic acid. A less heat is thus required in the evaporation, and impurities in the morphia may often be detected, as they are apt to be insoluble in alcohol. To ascertain, in this case, whether the morphia is saturated, it is necessary to employ litmus paper, the blue colour of which should not be restored, if previously reddened by an acid. If the morphia used in preparing the acetate contain narcotina, it

will be best to employ as the solvent distilled vinegar, or diluted acetic acid of the same strength, and to favour its solvent power by heat. Under these circumstances it dissolves only the morphia, leaving the narcotina nearly or quite untouched. (Hodgson, *Journ. of the Philad. Col. of Pharm.*, v. 35.)

Acetate of morphia crystallizes in the form of slender needles united in fasciculi. It is readily dissolved by water, and less easily by alcohol. As ordinarily obtained, however, by evaporation to dryness, it is not entirely soluble in water a portion of it being uncombined morphia. To render it soluble, all that is necessary is to add a little distilled vinegar. The U. S. Pharmacopœia gives the following tests of its character. "From its solution potassa throws down a precipitate which is dissolved by an excess of the alkali. It is affected by heat, nitric acid, and sesquichloride of iron, in the same manner as morphia. When sulphuric acid is added to the salt, acetous vapours are evolved." In addition to these tests, the *London College*, in its late Pharmacopœia, referred to the property possessed by this and other salts of morphia, when treated first with chlorine and then with ammonia, of presenting a brown colour, which disappears on the further addition of chlorine. The *Edinburgh College* gave the following mode of testing its purity: "One hundred measures of a solution of ten grains in half a fluidounce of water and five minims of acetic acid, heated near to 212°, and decomposed by a faint excess of ammonia, yield by agitation a precipitate which in 24 hours occupies 15·5 measures of the liquid."

From an eighth to a quarter of a grain may be given for a dose, and repeated, if necessary, in order to obtain the anodyne and soporific effects of the medicine. One-sixth of a grain is about equivalent to a grain of opium. It may be given in pill or solution. It is frequently employed externally, sprinkled on blistered surfaces, to obtain its effects upon the system. W.

MORPHIÆ MURIAS. *U. S.* Morphiæ Hydrochloras. *Br. Muriate of Morphia. Hydrochlorate of Morphia.*

"Take of Morphia, in fine powder, *a troyounce;* Distilled Water *half a pint;* Muriatic Acid *a sufficient quantity.* Mix the Morphia with the Distilled Water; then carefully drop in Muriatic Acid, constantly stirring, until the Morphia is saturated and dissolved. Evaporate the solution, by means of a water-bath, so that on cooling it may crystallize. Lastly, drain the crystals, and dry them on bibulous paper." *U. S.*

"Take of Opium, sliced, *one pound* [avoirdupois]; Distilled Water *a sufficiency;* Chloride of Calcium *three-quarters of an ounce* [avoird.]; Solution of Ammonia *a sufficiency;* Purified Animal Charcoal *a quarter of an ounce* [avoird.]; Dilute Hydrochloric Acid *two fluidounces*, or *a sufficiency.* Macerate the Opium for twenty-four hours with two pints [Imperial measure] of the Water, and decant. Macerate the residue for twelve hours with two pints [Imp. meas.] of the Water, decant, and repeat the process with the same quantity of the Water, subjecting the insoluble residue to strong pressure. Unite the liquors, evaporate on a water-bath to the bulk of one pint [Imp. meas.], and strain through calico. Pour in now the Chloride of Calcium previously dissolved in four fluidounces of Distilled Water, and evaporate until the solution is so far concentrated that, upon cooling, it becomes solid. Envelope the mass in a double fold of strong calico, and subject it to powerful pressure, preserving the dark fluid which exudes. Triturate the squeezed cake with about half a pint [Imp. meas.] of boiling Distilled Water, and, the whole being thrown upon a paper filter, wash the residue well with boiling Distilled Water. The filtered fluids having been evaporated as before, cooled, and solidified, again subject the mass to pressure; and, if it be still much coloured, repeat this process a third time, the expressed liquids being always preserved. Dissolve the pressed cake in six fluidounces of boiling Distilled Water; add the Animal Charcoal, and digest for

twenty minutes; filter, wash the filter and charcoal with boiling Distilled Water, and to the Solution thus obtained add the Solution of Ammonia in slight excess. Let the pure crystalline Morphia which separates as the liquid cools, be collected on a paper filter, and washed with cold Distilled Water until the washings cease to give a precipitate with solution of nitrate of silver acidulated by nitric acid.

"From the dark liquids expressed in the above process an additional product may be obtained by diluting them with distilled water, precipitating with solution of potash added in considerable excess, filtering, and supersaturating the filtrate with hydrochloric acid. This acid liquid digested with a little animal charcoal, and again filtered, gives upon the addition of ammonia a small quantity of pure morphia.

"Diffuse the pure morphia obtained as above, through two fluidounces of boiling Distilled Water placed in a porcelain capsule kept hot, and add, constantly stirring, the Dilute Hydrochloric Acid, proceeding with caution, so that the morphia may be entirely dissolved, and a neutral solution obtained. Set aside to cool and crystallize. Drain the crystals, and dry them on filtering paper. By further evaporating the mother-liquor, and again cooling, additional crystals are obtained." *Br.*

In relation to the process of the U. S. Pharmacopœia, the remarks made upon the preparation of the sulphate of morphia are equally applicable here. (See *Morphiæ Sulphas.*) The troyounce of morphia, directed in the formula, is not soluble, even when converted into the muriate, in half a pint of cold water; and the process, if exactly followed, could not be carried out. By inadvertence, the direction was omitted to use the water of solution boiling hot, in which condition it will readily dissolve the whole of the muriate produced. The British process is based upon the plan, originally suggested by Wittstock, improved by Dr. Wm. Gregory, and adopted in the Edinburgh Pharmacopœia, of obtaining muriate of morphia immediately from opium without the use of alcohol. The meconate and a little sulphate of morphia extracted by water from opium are decomposed by chloride of calcium, yielding muriate of morphia in solution, and meconate and sulphate of lime as precipitates. The next step consists in purifying the solution of the muriate by repeated evaporation, crystallization, expression, and re-solution, and finally the action of animal charcoal; the dark expressed liquors being set aside for future operation. The third step in the process is to obtain the morphia separate by precipitation by means of ammonia from the solution of the muriate. Lastly, the crystallized morphia is reconverted, by treatment with muriatic acid and hot water, into the muriate of morphia, which crystallizes from the solution as it cools. The reserved expressed liquors are united, and made to give up their morphia by the reagency of potassa in excess, which at once separates and dissolves the alkaloid. The solution yields it in a crystalline state on the addition of muriatic acid in excess, and afterwards of ammonia. The morphia thus obtained is added to that first procured, and with it again converted into the muriate. Dr. Christison says, in favour of Dr. Gregory's process, that the Edinburgh manufacturers, who follow it, produce a salt of unrivalled purity and cheapness. But it is much better calculated for the large laboratory of the manufacturing chemist, than for the smaller operations of the apothecary, who will probably find the U. S. process more convenient.

Muriate of morphia procured by the old Edinburgh process is free from narcotina; but always contains a portion of muriate of codeia, which, however, is scarcely sufficient to affect its operation upon the system. Dr. Christison found the proportion to vary between a 60th in the muriate prepared from good Turkey opium, a 30th in that from inferior samples of the same variety, and a 12th in that from the East Indian. This impurity may be separated by precipitating the morphia by means of ammonia; the codeia being left in solution; and this no doubt is

the object of the last step of the present British process, previously to the final conversion of the morphia into the muriate.

The late Dr. A. T. Thomson published a process for procuring muriate of morphia, which he found considerably more productive than that of the Edinburgh College. After macerating the opium in water, as directed by the College, for thirty hours, and expressing, he rubbed it in a mortar with an equal weight of pure white sand, and enough water to form the mixture into a paste, which he placed in a percolator, and subjected to the action of distilled water till the fluid passed without colour and taste. He then concentrated the liquor to the consistence of a thin syrup, added diacetate of lead, diluted the solution with twice its bulk of distilled water, allowed it to stand for twenty-four hours, decanted the supernatant liquid, washed the precipitate with warm water, added the washings to the decanted solution, and concentrated to one-half. To free the liquid from any remaining acetate of lead, he added diluted sulphuric acid in slight excess, decanted the liquid from the precipitate, washed the latter, added the washings to the solution, and boiled for some minutes to drive off acetic acid. To convert the sulphate of morphia now contained in the solution into muriate, he added a saturated solution of chloride of barium, washed the precipitate, evaporated the conjoined washings and solution to the point of crystallization, pressed the crystals, diluted and again evaporated the mother-liquor so long as it afforded crystals, which were purified by means of animal charcoal, and by repeated solution, evaporation, and crystallization. (*Pharm. Journ.*, i. 459.)

Muriate of morphia crystallizes in tufts of feathery acicular crystals. It is white, inodorous, bitter, soluble in 16 parts of water at 60°, and its own weight at 212°, and soluble also in alcohol. A saturated solution in boiling water forms a solid crystalline mass on cooling. The crystals are said to consist of one equivalent of morphia 285, one of muriatic acid 36·5, and six of water 54. Dr. Christison constantly found the crystals, when dried at 150°, to contain 12·7 per cent. of water; and the Edinburgh College stated that the loss of weight at 212° is not above 13 per cent. The salt may be known to be a muriate by yielding in solution, with nitrate of silver, a precipitate insoluble in nitric or muriatic acid, but dissolved by an excess of ammonia. Potassa throws down from its solution a precipitate which is redissolved by an excess of the alkali. The salt is affected by heat, nitric acid, iodic acid, sesquichloride of iron, and chlorine followed by ammonia, in the same manner as morphia. Sugar is said to have been used largely in the adulteration of this salt. It may be detected by the test of fermentation

"Twenty grains of the salt dissolved in half a [fluid]ounce of warm water with ammonia added in the slightest possible excess, give on cooling a crystalline precipitate, which, when washed with a little cold water, and dried by exposure to the air, weighs 15·18 grains." *Br.*

This preparation of morphia is much used in Great Britain, but, in this country, less than either the sulphate or acetate. The dose, equivalent to a grain of opium, is about one-sixth of a grain.

Off. Prep. Liquor Morphiæ Hydrochloratis, *Br.;* Suppositoria Morphiæ, *Br.;* Trochisci Morphiæ, *Br.;* Trochisci Morphiæ et Ipecacuanhæ, *Br.* W.

MORPHIÆ SULPHAS. *U. S. Sulphate of Morphia.*

"Take of Morphia, in fine powder, *a troyounce;* Distilled Water *half a pint;* Diluted Sulphuric Acid *a sufficient quantity.* Mix the Morphia with the Distilled Water, then carefully drop in Diluted Sulphuric Acid, constantly stirring until the Morphia is saturated and dissolved. Evaporate the solution, by means of a water-bath, so that on cooling it may crystallize. Lastly, drain the crystals, and dry them on bibulous paper." *U. S.*

In this process the morphia is known to be saturated when it is wholly dissolved by the water. To ascertain whether the acid is added in excess, litmus paper may be resorted to. If the morphia employed contain narcotina, this will

remain in the mother-liquor, and will not contaminate the product. The mother-liquor, remaining after the first crystallization, may be evaporated so as to afford a fresh supply of the sulphate; but, if the morphia was not originally quite pure, the second product will contain the impurities, and should not be used till it has undergone further preparation. When impure morphia is employed, the mother-liquor should be mixed with alcohol, or boiled with purified animal charcoal and filtered, and then decomposed by ammonia, which will precipitate the morphia. This may be converted into the sulphate in the manner directed by the Pharmacopœia.

Another mode of obtaining sulphate of morphia, is to dissolve the alkaloid in boiling alcohol of 36° Baumé (sp. gr. 0·8428), saturate it while hot with sulphuric acid, add purified animal charcoal, boil for a few minutes, and filter the solution at the boiling temperature. Upon cooling, it deposits most of the sulphate; and the remainder may be obtained by evaporating the mother-liquor.

In the evaporation of the solution of this salt, care should be taken not to carry the heat too far; for, when pushed to incipient decomposition with an excess of acid, a new substance is formed containing no morphia. (See *Am. Journ. of Pharm.*, xvii. 286.)

Sulphate of morphia crystallizes in beautifully white, minute, feathery crystals, which are soluble in cold water, and in twice their weight of boiling water. They contain, according to Liebig, in 100 parts, 10·33 of sulphuric acid, 75·38 of morphia, and 14·29 of water. By exposure to a heat of 248° F. they lose 9·66 parts of the water, but cannot be deprived of the remainder without decomposition. They are said to consist of one equivalent of morphia 285, one of sulphuric acid 40, and six of water 54, of which five are water of crystallization, and may be expelled by heat. The tests for it are those for sulphuric acid and for morphia. The dose is from an eighth to a quarter of a grain, which may be given in pill or solution.

MUCILAGINES.

Mucilages.

Mucilage, in the ordinary acceptation of the term, and in the sense in which it is employed in the U. S. Pharmacopœia, is an aqueous solution of gum, or of substances closely allied to it. In the British Pharmacopœia it is applied also to the semi-liquid, jelly-like substance, resulting from the cooling of a hot solution of starch. W.

MUCILAGO ACACIÆ. *U. S.*, *Br.* *Mucilage of Gum Arabic.*

"Take of Gum Arabic, in pieces, *four troyounces;* Water *half a pint.* Add the Water to the Gum Arabic, agitate occasionally until it is dissolved, and strain." *U. S.*

"Take of Gum Arabic, in small pieces, *four ounces* [avoirdupois]; Distilled Water *six fluidounces.* Suspend the Gum in a muslin bag under the surface of the Water, in a deep vessel; after thirty-six hours, squeeze out the fluid remaining in the bag, and mix." *Br.*

The gum used for this purpose should be in small fragments, or coarse powder, as it is more readily dissolved in this state than when finely pulverized. Straining is necessary to separate the foreign substances which are often mixed with gum arabic. This mucilage is semi-transparent, almost colourless if prepared from good gum, viscid, tenacious, of a feeble peculiar odour, and nearly tasteless. If the solution of gum should be coloured, it may be rendered colourless by the addition of a concentrated solution of chlorine; and, by boiling for about half an hour so as to drive off the chlorine and muriatic acid, it may be rendered fit for use. (*Guérin.*) By keeping, mucilage becomes sour, in conse

quence of the spontaneous generation of acetic acid; and this happens even though it be enclosed in well-stopped bottles. But, according to Guérin, the solution of pure gum undergoes no change in vacuo. Heat in its preparation is said to favour the production of acid; and hence cold has been substituted for boiling water in the present formulas. Mucilage is employed chiefly in the formation of pills, and for suspending or diffusing insoluble substances in water. Physicians, in prescribing mucilage in mixtures, should always recollect that it is a solution of definite strength, containing, according to the U. S. formula, half an ounce of the gum to each fluidounce of menstruum. The British mucilage is a little stronger. Half a fluidounce is usually sufficient for a six or eight ounce mixture.

Off. Prep. Trochisci Acidi Tannici, *Br.;* Troch. Morphiæ, *Br.;* Troch. Morphiæ et Ipecacuanhæ, *Br.* W.

MUCILAGO AMYLI. *Br. Mucilage of Starch.*

"Take of Starch *one hundred and twenty grains;* Distilled Water *ten fluidounces.* Triturate the Starch with the Water gradually added; then boil for a few minutes, constantly stirring." *Br.*

This mucilage has an opaline appearance, and gelatinous consistence, and is much used as a vehicle for laudanum and other active medicines given in the form of enema. In consequence of its demulcent properties, it may be usefully employed as an enema in irritation and inflammation of the mucous coat of the rectum and large intestines. Its unpleasant flavour, when it is prepared from ordinary starch, precludes its employment by the mouth.

Off. Prep. Enema Aloes, *Br.;* Enema Assafœtidæ, *Br.;* Enema Magnesiæ Sulphatis, *Br.;* Enema Opii, *Br.;* Enema Terebinthinæ, *Br.* W.

MUCILAGO SASSAFRAS. *U. S.* Infusum Sassafras Medullæ. *U. S.* 1850. *Mucilage of Sassafras. Infusion of Sassafras Pith.*

"Take of Sassafras Pith *one hundred and twenty grains;* Water [cold] *a pint.* Macerate for three hours, and strain." *U. S.*

This infusion is much used as an application to the eye in inflammation of the conjunctiva. It may be taken as a drink, *ad libitum*, in inflammatory and febrile diseases, particularly inflammations of the mucous passages. W.

MUCILAGO TRAGACANTHÆ. *U. S., Br. Mucilage of Tragacanth.*

"Take of Tragacanth *a troyounce;* Boiling Water *a pint.* Macerate the Tragacanth with the Water for twenty-four hours, occasionally stirring; then rub them together so as to render the mixture uniform, and strain forcibly through linen." *U. S.*

"Take of Tragacanth *one hundred grains;* Boiling Distilled Water *ten fluidounces.* Macerate for twenty-four hours, then triturate, and express through calico." *Br.*

A part only of tragacanth is soluble in water. The remainder swells up and forms a soft tenacious mass, which may be mechanically mixed with water, but does not form a proper solution. Hence trituration is necessary to complete the incorporation of the ingredients. This mucilage is thick and very viscid, but not permanent, as the water separates from the insoluble portion of the tragacanth on standing. It is chiefly used in making pills and troches. From its great tenacity, it may be advantageously employed for the suspension of heavy insoluble substances, such as the metallic oxides, in water. When kept long it is apt to undergo decomposition, and to become offensive. Mr. Maisch has found a paste of tragacanth to keep perfectly well by the addition of enough creasote to impart its characteristic odour faintly. (*Am. Journ. of Pharm.*, March, 1864, p. 97.)

Off. Prep. Trochisci Ferri Subcarbonatis, *U. S.;* Trochisci Ipecacuanhæ, *U. S.;* Trochisci Magnesiæ, *U. S.;* Trochisci Menthæ Piperitæ, *U. S.;* Trochisci Sodæ Bicarbonatis, *U. S.* W.

MUCILAGO ULMI. *U. S.* INFUSUM ULMI. *U. S.* 1850. *Mucilage of Slippery Elm Bark. Infusion of Slippery Elm Bark.*

"Take of Slippery Elm Bark, sliced and bruised, *a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." *U. S.*

This may be used *ad libitum* as a demulcent and nutritious drink in catarrhal and nephritic diseases, and in inflammatory affections of the intestinal mucous membrane. It is much employed locally as a demulcent in inflammation of the skin, as in erysipelas, &c. W.

OLEA DESTILLATA.

Distilled Oils.

For an account of the general properties of the volatile or distilled oils, the reader is referred to the head of *Olea Volatilia* in the first part of this work. The following are the U. S. general directions for preparing them.

OLEA DESTILLATA. *U. S.*

"Most of the Distilled Oils are prepared by the following general formula. Put the substance from which the Oil is to be extracted into a retort, or other vessel suitable for distillation, and add enough water to cover it; then distil by a regulated heat into a large refrigeratory. Separate the Distilled Oil from the water which comes over with it."

In this manner are prepared OIL OF ANISE, from Anise, bruised; OIL OF CARAWAY, from Caraway, bruised; OIL OF CLOVES, from Cloves, bruised; OIL OF WORMSEED, from Wormseed; OIL OF CUBEB, from Cubeb, bruised; OIL OF CANADA FLEABANE, from Canada Fleabane; OIL OF FENNEL, from Fennel, bruised; OIL OF GAULTHERIA, from fresh Gaultheria [leaves]; OIL OF HEDEOMA, from Hedeoma; OIL OF JUNIPER, from Juniper [berries], bruised; OIL OF LAVENDER, from Lavender [flowers]; OIL OF PEPPERMINT, from fresh Peppermint; OIL OF SPEARMINT, from fresh Spearmint; OIL OF HORSEMINT, from fresh Horsemint; OIL OF PIMENTO, from Pimento, bruised; OIL OF ROSEMARY, from Rosemary [tops]; OIL OF SAVINE, from Savine, bruised; OIL OF SASSAFRAS, from Bark of Sassafras Root, bruised; and OIL OF VALERIAN, from Valerian, bruised.

The *British Council* gives no directions for the preparation of the volatile oils, but places such as it recognises in the Materia Medica catalogue. The following general directions of the late Edinburgh Pharmacopœia, published in former editions of the Dispensatory, are retained in the present.

"Substances yielding volatile oils must be distilled with water, the proper proportion of which varies for each article, and for the several qualities of each. In all instances, the quantity must be such as to prevent any of the material from being empyreumatized before the whole oil is carried over. In operations where the material is of a pulpy consistence, other contrivances must be resorted to for the same purpose. These consist chiefly of particular modes of applying heat, so as to maintain a regulated temperature not much above 212°. On the small scale, heat may be thus conveniently applied by means of a bath of a strong solution of muriate of lime, or by means of an oil-bath, kept at a stationary temperature with the aid of a thermometer. On the large scale, heat is often applied by means of steam under regulated pressure. In other operations it is found sufficient to hang the material within the still in a cage or bag of fine net-work; and sometimes the material is not mingled with the water at all, but is subjected to a current of steam passing through it.

"The best mode of collecting the oil is by means of the refrigeratory described in the preface [see *page* 889], from which the water and oil drop together into a tall narrow vessel, provided with a lateral tube or lip near the top, and another

tube rising from the bottom to about a quarter of an inch below the level of the former. It is evident that, with a receiver of this construction, the water will escape by the lower tube; while the volatile oil, as it accumulates, will be discharged by the upper one, except in the very few instances where the oil is heavier than the water."

Under the general observations on the *Aquæ* or *Waters* (*page* 992) will be found remarks upon the use of steam in preparing the Distilled Waters, which are to a considerable extent applicable also to the volatile oils.

The substances from which the volatile oils are extracted may be employed either in the recent or dried state. Certain flowers, however, such as orange flowers and roses, must be used fresh, or preserved with salt, as they afford little or no oil after exsiccation. Most of the aromatic herbs, also, as peppermint, spearmint, pennyroyal, and marjoram, are usually distilled while fresh; although it is thought by some that, when moderately dried, they yield a larger and more grateful product. Dried substances, before being submitted to distillation, require to be macerated in water till they are thoroughly penetrated by this fluid; and, to facilitate the action of the water, it is necessary that, when of a hard or tough consistence, they should be properly comminuted by slicing, shaving, rasping, bruising, or other similar mechanical operation.

The water which is put with the subject of distillation into the alembic, answers the double purpose of preventing the decomposition of the vegetable matter by regulating the temperature, and of facilitating the volatilization of the oil, which, though in most instances it readily rises with the vapour of boiling water, requires, when distilled alone, a considerably higher temperature, and is at the same time liable to be partially decomposed. Some oils, however, will not ascend readily with steam at 212°; and in the distillation of these it is customary to use water saturated with common salt, which does not boil under 230°. Recourse may also be had to a bath of strong solution of chloride of calcium, or to an oil-bath, the temperature of which is regulated by a thermometer, as suggested by the Edinburgh College in their general directions. (See *page* 1244.) Other oils again may be volatilized with water at a temperature below the boiling point; and, as heat exercises an injurious influence over the oils, it is desirable that the distillation should be effected at as low a temperature as possible. To prevent injury from heat, it has been recommended to suspend the substance containing the oil in a basket, or to place it upon a perforated shelf, in the upper part of the alembic, so that it may be penetrated by the steam, without being in direct contact with the water. Another mode of effecting the same object is to distil it *in vacuo*. Dr. Duncan stated that the most elegant volatile oils he had ever seen were prepared in this manner by Mr. Barry, the inventor of the process. The employment of steam heat also prevents injury; and the best volatile oils are now prepared in Philadelphia in this way. Steam can be very conveniently applied to this purpose by causing it to pass through a coil of leaden tube of an inch or three-quarters of an inch bore, placed in the bottom of a common still. The end at which the steam is admitted enters the still at the upper part, and the other end, at which the steam and condensed water escape, passes out laterally below, being furnished with a stop-cock, by which the pressure of the steam may be regulated, and the water drawn off if necessary. In some instances, it is desirable to conduct the steam immediately into the still near the bottom, by which the contents are kept in a state of brisk ebullition. This method is used in the preparation of the oil of bitter almonds and the oil of mustard. The same method is applicable to the preparation of the distilled waters.

The quantity of water added is not a matter of indifference. An excess above what is necessary acts injuriously by holding the oil in solution, when the mixed vapours are condensed; and, if the proportion be very large, it is possible that

no oil whatever may be obtained separate. On the contrary, if the quantity be too small, the whole of the oil will not be distilled; and there will be danger of the substance in the alembic adhering to the sides of the vessel, and thus becoming burnt. Enough water should always be added to cover the solid material, and prevent the latter accident. Dried plants require more water than the fresh and succulent. The whole amount of materials in the alembic should not exceed three-fourths of its capacity; as otherwise there would be danger of the liquor boiling over. The form of the alembic has an influence over the quantity of water distilled, which depends more upon the extent of surface than the amount of liquid submitted to evaporation. By employing a high and narrow vessel, we may obviate the disadvantage of an excess of water. The broad shallow alembic, suitable for the distillation of alcohol and spirituous liquors, will not answer so well in this case. Sometimes the proportion of oil in the substance employed is so small that it is wholly dissolved in the water distilled, even though the proportion of the liquid in the alembic is not greater than is absolutely essential. In this case it is necessary to redistil the same water several times from fresh portions of the plant, till the quantity of oil which comes over exceeds its solvent power. This process is called *cohobation.*

The more volatile of the oils pass with facility along with the steam into the neck of the common still; but some which are less volatile are apt to condense in the head, and thus return into the alembic. For the distillation of the latter, a still should be employed with a large and very low head, having a rim or gutter around its internal circumference, into which the oils may be received as they condense, and thence pass into the neck. (See *page* 992.) As, after the distillation of any one oil, it is necessary that the apparatus should be thoroughly cleansed before being used for the preparation of another, it is better that the condensing tube should be straight, than spiral as in the ordinary still. It should be recollected, moreover, that certain oils, such as those of anise and fennel, become solid by a comparatively slight reduction of temperature; and that, in the distillation of these, the water employed for refrigeration should not be below 42° F.

The mixed vapours are condensed into a milky liquid, which is collected in a receiver, and, after standing for some time, separates into the oil and a clear solution of it; the former floating on the surface, or sinking to the bottom, according as it is lighter or heavier than water. The distillation should be continued so long as the fluid which comes over has this milky appearance.

The last step in the process is to separate the oil from the water. For this purpose the *Florence receiver* may be used. This is a conical glass vessel, broad at the bottom and narrow towards the top, and very near its base furnished with a tubulure or opening, to which is adapted, by means of a pierced cork, a bent tube so shaped as to rise perpendicularly to seven-eighths of the height of the receiver, then to pass off from it at right angles, and near the end to bend downwards. The condensed liquid being admitted through the opening at the top of the receiver, the oil separates, and rising to the top occupies the upper narrow part of the vessel, while the water remains at the bottom, and enters the tube affixed to the receiver. When the surface of the liquid attains in the receiver a higher level than the top of the tube, the water will necessarily begin to flow out through the latter, and may be received in bottles. The oil thus accumulates so long as the process continues; but it is evident that the plan is applicable only to the oils lighter than water. For the heavier oils, cylindrical vessels may be employed, to be renewed as fast as they are filled. But, as all the water cannot be removed by these plans, it is necessary to resort to some other method of effecting a complete separation. An instrument called a *separatory* is usually employed for this purpose. It consists of a glass funnel, bulging at the top, where it is furnished with a stopper, and prolonged at the bottom into a very narrow tube. (See *figure*, *page* 884.) The lower opening being closed,

the mixed liquids are introduced and allowed to stand till they separate. The orifice at the bottom is then opened, and, the stopper at the top being a little loosened so as to admit the air, the heavier liquid slowly flows out, and may be separated to the last drop from the lighter, which floats above it. If the oil is heavier than the water, it passes out of the separatory; if lighter, it remains within. Another mode of separating the oil is to introduce into the vessel containing the two liquids one end of a cord of cotton, the other end hanging out, and terminating in a suitable receptacle beneath the level of that immersed in the liquid. The oil at top passes through the cord, and may thus be wholly removed. The last drops may be collected by pressing the cord between the fingers.

The water saturated with oil should be preserved for future distillations; as it can dissolve no more of the oil. One or more volatile acids are frequently found in the distilled water, as the acetic, butyric, or valerianic; and Wunder has detected all three of these acids in the water distilled from chamomile flowers. (*Journ. für Prakt. Chem.*, lxiv. 499.)

According to Overbeck, all the volatile oils may be freed from colouring matter by distilling them from an equal weight of poppy-seed oil, and a saturated solution of common salt. (*Archiv. der Pharm.*, lxxxiv. 149.)

When first procured, the oils have a disagreeable empyreumatic odour, from which they may be freed by allowing them to stand for some days in vessels loosely covered with paper. They should then be introduced into small opaque bottles, which should be well stopped so as to exclude the air. When altered by exposure to air, they may sometimes be restored to their original appearance and quality, by agitation with a little recently heated animal charcoal; and the same method may be employed for freeing them from adhering water.

The volatile oils have the medical properties of the plants from which they are derived; and, as their remedial application has been mentioned under the heads of these plants respectively, it will be unnecessary to treat of it in this place. They may be administered upon a lump of sugar; or triturated with at least ten times their weight of sugar, forming an *oleo-saccharum*, and then dissolved in water; or made into an emulsion with water, sugar, and gum arabic. In making emulsions with volatile oils, it has been recommended first to dissolve them in one of the fixed oils, the oil of almonds for example, and then to emulsionize the oleaginous solution with syrup and gum arabic. For 100 parts of water, 15 of the almond oil in which the volatile oil is to be dissolved, 10 of powdered gum arabic, and 25 of syrup may be taken. (*Journ. de Pharm.*, Juin, 1864, p. 461.) The volatile oils are often kept dissolved in alcohol under the name of *essences*.* W.

* It is often important to know how many drops a volatile oil will yield to the fluidrachm; in other words, the relation of a drop of the oil to a minim. This varies extremely according to the circumstances elsewhere noticed as influencing the size of the drop; so that any results obtained are only approximate and relative. At our request, Professor Procter tried the following oils, with the results stated in the table below. The columns of figures represent the number of drops in a fluidrachm of the oils respectively, the first column giving those obtained by dropping the oils from the bottles in which they are commonly kept, the second by dropping them from a minim measure.

Enfleurage. This term is applied by the French to the impregnation of fixed oils and fatty matters with the odour of certain sweet-scented plants, such as jasmine, tuberose, and mignonette, the oils of which are so delicate and fugitive that they cannot well be separated by distillation. The process consists in exposing the fatty matter, placed in

OLEUM ANISI. *U. S., Br. Oil of Anise.*

The British Pharmacopœia refers the oil of anise not only to Pimpinella Anisum, but also to Illicium anisatum.

The product of oil from anise is variously stated from 1·56 to 3·12 per cent. The oil employed in this country is imported. It is colourless or yellowish, with the peculiar odour and taste of the seed. At 50° it crystallizes in flat tables, and does not melt under 62°. Its sp. gr. increases with age, and is variously given from 0·9768 to 0·9903. It is soluble in all proportions in alcohol of 0·806; but alcohol of 0·840 dissolves at 77° only 42 per cent. Ether dissolves it in all proportions. (*Gmelin.*) It consists of two oils, one solid at ordinary temperatures and heavier than water (*stearoptene, anise camphor, solid anethol*), the other liquid and more volatile (*eleoptene, liquid anethol*), both of which are said to have the same atomic constitution, and to consist of carbon, hydrogen, and oxygen ($C_{20}H_{12}O_2$). *Anethol* is a name given to the solid and liquid oils, all having the composition above stated, but differing in properties, which mainly constitute the oils of *anise*, of *star aniseed*, and of *fennel*. (*Gmelin's Handbook*, xiv. 192.) By oxidation, by means of nitric or chromic acid, the different forms of anethol yield a peculiar acid denominated *anisic acid*. (*Ibid.*, xiii. 123.) Oil of anise absorbs oxygen from the air, and becomes less disposed to concrete. In consequence of its high price, it is frequently adulterated with spermaceti, wax, or camphor. The first two may be detected by their insolubility in cold alcohol, the last by its odour. In one instance, as much as 35 per cent. of spermaceti was found. Prof. Procter has met with a parcel, of which not less than five-sixths were alcohol. (*Am. Journ. of Pharm.*, xxvii. 513.) The dose of the oil is from five to fifteen drops. Its comparative mildness adapts it to infantile cases. We are informed that the oil of anise has, in this country, been almost entirely superseded by the *oil of star aniseed* (*oleum badiani*), which closely resembles it in flavour, and which is recognised in the Br. Pharmacopœia under the same name. (See *page* 119.)

W.

OLEUM CARI. *U. S.* OLEUM CARUI. *Br. Oil of Caraway.*

"The Oil distilled in England from Caraway." *Br.*

This oil is prepared to a considerable extent by our distillers. The fresh fruit yields on an average about 4·7 per cent. (*Recluz*); but the product is very variable. The oil of caraway is somewhat viscid, of a pale-yellow colour becoming brownish by age, with the odour of the fruit, and an aromatic acrid taste. Its sp. gr. is differently given at 0·946 (*Baumé*), 0·931 (*Brande*), and 0·916 (*Buignet*). It is dextrogyrate in its relation to polarized light. (Buignet, *Journ. de Pharm.*, Oct. 1861, p. 261.) It consists of two liquid oils, of different boiling points, and separable by distillation; one, a carbohydrogen called *carvene* ($C_{20}H_{16}$, *Völkel*), of the sp. gr. 0·861, and boiling point 343° F.; the other composed of carbon, hydrogen, and oxygen ($C_{20}H_{14}O_2$), and named *carvol*, of the sp. gr. 0·953, and boiling point 482° F. Oil of caraway is much used to impart flavour to medicines, and to correct their nauseating and griping effects. The dose is from one to ten drops.

When oil of caraway is distilled from hydrated phosphoric acid, the distilled

layers, in suitable frames, to the exhalations from the flowers, which are absorbed, and give their characteristic odour to the fat. Another plan is to expose alternate layers of the flowers, and of cotton impregnated with bland fixed oil, to the sun, and afterwards to express the oil from the cotton. For remarks on this process, as conducted in the South of France, see a communication from Mr. Daniel Hanbury in the *London Pharm. Journ.*, copied into the *Am. Journ. of Pharm.* (xxix. 551).—*Note to the eleventh edition.*

liquor being poured back into the retort until it ceases to have the smell of caraway, an oily liquid is obtained, having a very disagreeable odour, and a strong taste. This product, to which the name of *carvacrol* has been applied, has been found to give immediate relief to toothache, when inserted on cotton into the cavity of a carious tooth. (See *Am. Journ. of Med. Sci.*, N. S., xv. 532.)

W.

OLEUM CARYOPHYLLI. *U. S.*, *Br. Oil of Cloves.*

"The Oil distilled in England from Cloves." *Br.*

This oil is obtained by distilling cloves with water, to which it is customary to add common salt, in order to raise the temperature of ebullition; and the water should be repeatedly distilled from the same cloves, in order completely to exhaust them. Professor Scharling has found advantage from the application of super-heated steam to the distillation of this oil. (*Pharm. Journ.*, xi. 469.)* The product of good cloves is said to be about one-fifth or one-sixth of their weight. The oil was formerly brought from Holland or the East Indies; but, since the introduction of the Cayenne Cloves into our markets, the reduced price and superior freshness of the drug have rendered the distillation of oil of cloves profitable in this country; and the best now sold is of domestic extraction. We have been informed that from seven to nine pounds of cloves yield to our distillers about one pound of the oil.

Properties. Oil of cloves, when recently distilled, is very fluid, clear, and colourless, but becomes yellowish by exposure, and ultimately reddish-brown. It has the odour of cloves, and a hot, acrid, aromatic taste. Its sp. gr. is variously stated at from 1·034 to 1·061; the latter being given by Bonastre as the sp. gr. of the rectified oil. It is one of the least volatile of the essential oils, and requires for congelation a temperature from zero of Fahrenheit to —4°. It is completely soluble in alcohol, ether, and strong acetic acid. Nitric acid changes its colour to a deep red, and converts it by the aid of heat into oxalic acid. When long kept it deposits a crystalline *stearoptene*. It is frequently adulterated with fixed oils, and sometimes with oil of pimento and with copaiba. When pure it sinks in distilled water. According to Zeller, its character of congealing entirely into a crystalline mass with the alcoholic solution of potassa, losing at the same time its peculiar odour, affords a sufficient criterion of its purity. It appears to be indifferent in its effects on polarized light, as regards rotatory power. (*Buignet.*)

According to Ettling, the oil of cloves consists of two distinct oils, one lighter, the other heavier than water. They may be obtained separate by distilling the oil from a solution of potassa. The lighter comes over, the heavier remains combined with the potassa, from which it may be separated by adding sulphuric acid, and again distilling. *Light oil of cloves* is colourless, has the sp. gr. 0·918, and consists exclusively of carbon and hydrogen, being isomeric with pure oil of turpentine. It is said not to possess active properties. (*Kane.*) *Heavy oil of cloves* is colourless at first, but darkens with age, has the odour and taste of cloves, is of the sp. gr. 1·079, boils at 470°, and forms soluble and crystallizable salts with the alkalies. Hence it has been called *eugenic* or *caryophyllic acid.* It consists of carbon, hydrogen, and oxygen; the formula, according to Ettling, being $C_{24}H_{15}O_5$; according to Gerhardt, who is probably correct, $C_{20}H_{12}O_4$. (*Chem. Gaz.*, No. 373, p. 170.)

Medical Properties and Uses. The medical effects of the oil are similar to those of cloves, and it is used for the same purposes; but its most common em-

* For an account of the apparatus employed, and the method pursued by Messrs. Rogers and Crew, of Philadelphia, in the distillation of this oil, see *Am. Journ of Pharm.*, Jan. 1862, p. 27.

ployment is as a corrigent of other medicines. Like other powerful irritants, it is sometimes effectual in relieving toothache, when introduced into the cavity of a carious tooth. The dose is from two to six drops.

Off. Prep. Confectio Scammonii, *Br.;* Pilula Colocynthidis Composita, *Br.;* Pil. Colocynthidis et Hyoscyami, *Br.* W.

OLEUM CHENOPODII. *U. S. Oil of Wormseed.*

This oil is peculiar to the United States. The best is prepared in the vicinity of Baltimore. (See *page* 245.) It is of a light-yellow colour when recently distilled, but becomes deeper yellow and even brownish by age. It has in a high degree the peculiar flavour of the plant. When freshly prepared, it has the sp. gr. 0·908, which, according to Mr. S. S. Garrigues, is increased by time to 0·960. A portion examined by him, which was of a brownish-yellow colour, had the sp. gr. 0·959 at 61° F., boiled at 374°, and was freely soluble in alcohol and ether. He found it to consist of two distinct oils, separable by distillation; one of which consists of carbon and hydrogen exclusively, and reacts with muriatic acid in a manner analogous to oil of turpentine; the other is heavier, and consists of carbon, hydrogen, and oxygen. (*Am. Journ. of Pharm.*, xxvi. 405.) Wormseed oil is used as an anthelmintic, in the dose of from four to eight drops for a child, repeated morning and evening for three or four days, and then followed by a brisk cathartic. The case of a child, six years old, is recorded in the *Boston Med. and Surg. Journ.* (xlv. 373), in which death is supposed to have resulted from the use of overdoses. W.

OLEUM COPAIBÆ. *U. S., Br. Oil of Copaiba.*

"The Oil distilled from Copaiva." *Br.*

"Take of Copaiba *twelve troyounces;* Water *sixteen pints.* Add the Copaiba to the Water in a tinned still, and, having adapted a proper refrigeratory, distil twelve pints. Separate the Oil which comes over from the Water, return this latter to the still, and again distil twelve pints. Lastly, separate the Oil procured in the second distillation, add it to that first obtained, and keep the whole in a well-stopped bottle." *U. S.*

The oil constitutes from one-third to one-half or more of the copaiba. From one specimen of recent copaiba as much as 80 per cent. has been obtained. (*Am. Journ. of Pharm.*, xxii. 289.) It is prepared largely in Philadelphia by the application of steam heat. As it first comes over it is colourless, but the later product is of a fine greenish hue. By redistillation it may be rendered wholly colourless. It has the odour and taste of copaiba, boils at about 470° (*Christison*), solidifies, partly crystalline, at —15° F. (*Gmelin*), is soluble in ether and alcohol, absorbs muriatic acid gas, and forms with it crystals of artificial camphor, and when pure consists exclusively of carbon and hydrogen, being isomeric with pure oil of turpentine. From its want of oxygen, it answers even better than naphtha for preserving potassium, a fact first observed by Mr. Durand, of Philadelphia. It dissolves sulphur and phosphorus. (*Gmelin's Handbook*, xiv. 288.)

Its effects on the system are those of copaiba. From the experiments of C. Mitscherlich, it is one of the least injurious to the animal system of the volatile oils; six drachms of it having been introduced into the stomach of a rabbit without causing death. Externally it produces much less irritation than oil of turpentine. It may be used for the same purposes as copaiba in the dose of ten or fifteen drops, given in emulsion, or simply dropped on sugar. W.

OLEUM CORIANDRI. *Br. Oil of Coriander.*

"The Oil distilled in England from Coriander." *Br.*

This is obtained by distillation with water from the bruised seeds in the manner directed in the U. S. Pharmacopœia for the other volatile oils. Forty-two grains of it are stated by Zeller to be derived from a pound of the fruit. It is pale-yellow and colourless, and has the characteristic smell and taste of corian-

der. Its sp. gr. is from 0·859 to 0·871; and its boiling point 302° F. It is an oxygenated oil, with the formula $C_{20}H_{18}O_2$. Oil of coriander has the medical properties of the fruit, and, like the aromatic oils generally, may be used to cover the taste, or correct the nauseating or griping properties of other medicines.

Off. Prep. Syrupus Sennæ, *Br.* W.

OLEUM CUBEBÆ. *U.S.*, *Br.* *Oil of Cubeb.*

"The Oil distilled in England from Cubebs." *Br.*

This oil is obtained from cubebs by grinding them, and then distilling with water. From ten pounds Schönwald procured eleven ounces of oil; and this result very nearly coincides with the experiments of Christison, who obtained ˜ per cent. When recently distilled from the fruit, the oil is somewhat greenish, becoming yellowish by age; but when carefully redistilled it is colourless. It has the smell of cubebs, and a warm, aromatic, camphorous taste; is of a consistence approaching that of almond oil; is lighter than water, having the sp. gr. 0·929; and, when exposed to the air, is said to thicken without losing its odour. Upon standing, it sometimes deposits crystals, which are thought to be a hydrate of the oil. It consists of carbon and hydrogen, with the formula $C_{15}H_{12}$.

The oil has the medicinal properties of cubebs; but it is probably not the sole active ingredient; as it is much less pungent than the fluid extract or oleo-resin. It may, however, often be advantageously substituted for the powder, in the commencing dose of ten or twelve drops, to be gradually increased until its effects are obtained, or until it proves offensive to the stomach. It may be given suspended in water by means of sugar, or in the form of emulsion, or enclosed in capsules of gelatin. W.

OLEUM ERIGERONTIS CANADENSIS. *U.S.* *Oil of Canada Fleabane.*

The oil of fleabane is limpid, of a light-straw colour, a peculiar aromatic persistent odour, and a mild characteristic taste. Its sp. gr., according to Prof. Procter, is 0·845. It probably consists of two distinct oils, as it begins to boil at 310° F.; and its temperature continues to rise to 365°. When distilled without water, it comes over colourless, and a little resinous matter is left behind, probably resulting from the oxidation of one or both of the constituent oils. It consists of carbon, hydrogen, and oxygen. It is slowly reddened by potassa, combines with iodine without explosion, is instantly decomposed by sulphuric acid, and is acted on by strong nitric acid, slowly at ordinary temperatures, but with heat explosively. (Procter, *Am. Journ. of Pharm.*, xxvi. 502.)

It was first brought into notice by the so-called eclectic physicians, who use it in diarrhœa, dysentery, and the hemorrhages. In a communication by Dr. Wilson, of Philadelphia, to the College of Physicians (Nov. 1, 1854), it is stated that the *oil of Philadelphia fleabane* had been employed with great advantage by Dr. Bournonville and himself in uterine hemorrhage. (*Trans. of Col. of Phys.*, N. S., ii. 330.) There can be little doubt, from the account of the oil at the same time given, that it was the oil of *E. Canadense*, or that now under consideration, which was really used; as *E. Philadelphicum* yields merely a trace of volatile oil when distilled; Mr. J. F. John having obtained only half a fluidrachm of it from 45 avoirdupois pounds of the herb. (*Am. Journ. of Pharm.*, xxvii. 105.) It probably acts very much as the oil of turpentine as a hæmostatic. The dose is from five to ten drops, which should be repeated every hour or two. W.

OLEUM FŒNICULI. *U.S.* *Oil of Fennel.*

Fennel seeds yield about 2·5 per cent., or, according to Zeller, from 3·4 to 3·8 per cent. of oil. That used in this country is imported. It is colourless or yellowish, with the odour and taste of the seeds. Its sp. gr. is 0·984 to 0·997. It congeals below 50° into a crystalline mass, separable by pressure into a solid

and liquid oil (*stearoptene* and *eleoptene*); the former heavier than water, and less volatile than the latter, which rises first when the oil is distilled. As found in the shops, therefore, the oil of fennel is not uniform; and a specimen examined by Dr. Montgomery did not congeal at 22°. It consists of carbon, hydrogen, and oxygen; its formula being, according to Blanchet and Sell, $C_{13}H_8O_2$. Its two component oils are now distinguished by the names of *liquid* and *solid anethol*, isomeric with the similar constituents of oil of anise. (See *Oleum Anisi.*) It is slightly dextrogyrate. The dose is from five to fifteen drops.

Off. Prep. Aqua Fœniculi, *U. S.;* Spiritus Juniperi Compositus, *U. S.* W.

OLEUM GAULTHERIÆ. *U. S. Oil of Gaultheria.*

This oil is a product of the United States, and is prepared chiefly in New Jersey. It is directed by the Pharmacopœia to be prepared from the leaves of *Gaultheria procumbens;* but the whole plant is usually employed. It has been obtained by Prof. Procter from the bark of *Betula lenta* or sweet birch, and has been supposed to exist also in the root of *Polygala paucifolia*, and the roots and stems of *Spiræa ulmaria*, *Spiræa lobata*, and *Gaultheria hispidula*, which have its peculiar flavour.

Oil of partridge-berry when freshly distilled is nearly colourless, but as found in the shops has a brownish-yellow or reddish colour. It is of a sweetish, slightly pungent, peculiar taste, and a very agreeable characteristic odour, by which it may be readily distinguished from all other officinal oils. It is the heaviest of the known essential oils, having the sp. gr. 1·173. Its boiling point is 412°. (*Am. Journ. of Pharm.*, iii. 199, and xiv. 213.) Its unusual weight affords a convenient test of its purity. Another distinguishing property is that, in watery solution, it gives a purple colour with the salts of sesquioxide of iron. Prof. Procter proved it to possess acid properties, and to be closely analogous to *salicylous acid*, one of the results of the decomposition of salicin by sulphuric acid and bichromate of potassa, and an ingredient in the oil of *Spiræa ulmaria.* (See *Salix.*) M. Cahours has since corroborated this view, and shown that one-tenth of the oil consists of a peculiar carbohydrogen, which is called *gaultherilen*, and the remaining nine-tenths of *salicylate of oxide of methyl*, or *methylsalicylic acid;* and a product having the properties of the latter compound was obtained by distilling a mixture of pyroxylic spirit, salicylic acid, and sulphuric acid. (*Ibid.*, xiv. 211, and xv. 241.) Methylsalicylic acid forms with bases crystalline salts, which are resolved by heat into salicylic acid and wood spirit. Dr. T. J. Gallaher, of Pittsburg, Pa., records the case of a boy, nine years old, who took about half an ounce of this oil, with the effect of producing severe vomiting, purging, epigastric pain, hot skin, frequent pulse, slow and laboured respiration, dulness of hearing, and, notwithstanding excessive gastric irritability, an uncontrollable desire for food. After two or three days of great danger, he began to improve, and in two weeks was entirely restored to health. (*Med. Examiner*, N. S., viii. 347.) Oil of gaultheria is chiefly used, on account of its pleasant flavour, to cover the taste of other medicines.

Off. Prep. Syrupus Sarsaparillæ Compositus, *U. S.* W.

OLEUM HEDEOMÆ. *U. S. Oil of Hedeoma. Oil of American Pennyroyal.*

This, though analogous in properties to the oil of European pennyroyal, is derived from a distinct plant (*Hedeoma pulegioides*) peculiar to North America. It has a light-yellow colour, with the odour and taste of the herb. Its sp. gr. is 0·948. It may be used as a remedy in flatulent colic and sick stomach, to correct the operation of nauseating or griping medicines, and to impart flavour to mixtures. It is also much employed as a domestic remedy in amenorrhœa. The dose is from two to ten drops. W

OLEUM JUNIPERI. *U. S., Br. Oil of Juniper.*

"Juniperus communis. The Oil distilled in England from the unripe fruit." *Br.*

The proportion of oil which juniper berries afford is stated very differently by different authors. Trommsdorff obtained one per cent. The highest quantity given in the table of Recluz is 2·34, the lowest 0·31 per cent. Zeller gives as the product of the fresh ripe fruit 1·3 per cent., of that a year old 0·86 per cent (*Cent. Blatt*, März, 1855, p. 207.) The berries are most productive when bruised The oil of juniper consumed in this country is brought from Europe, and is believed to be procured chiefly from the tops of the plant, being sold for a price which is altogether incompatible with the idea that it is prepared from the fruit alone. It is colourless, or of a light greenish-yellow, with a terebinthinate odour, and hot acrid taste. Oil of Juniper has a sp. gr. from 0·879 to 0·911, and is moderately lævogyrate. (*Buignet.*) It is not very soluble in alcohol. According to Blanchet, it contains two isomeric oils, of which one is colourless, and the other coloured and less volatile. It is, when pure, a carbohydrogen, and is said to have the same composition as oil of turpentine ($C_{10}H_8$); but it does not form a solid compound with muriatic acid. (*Journ. de Pharm.*, xxvi. 80.) Oil of turpentine is often fraudulently added, but may be detected by the specific gravity of the mixture, which is considerably less than that of the unadulterated oil of juniper.

The oil is stimulant, carminative, and diuretic; and may be employed advantageously in debilitated dropsical cases, in connection with other medicines, especially digitalis. It is this oil which imparts to Holland gin its peculiar flavour and diuretic power. The dose is from five to fifteen drops two or three times a day, and may be considerably increased.

Off. Prep. Spiritus Juniperi, *Br.;* Spiritus Juniperi Compositus, *U. S.* W.

OLEUM LAVANDULÆ. *U. S., Br. Oil of Lavender.*

"Lavandula vera. The Oil distilled in England from the flowers." *Br.*

This oil is usually distilled from the flowers and flower-stems conjointly, though of finer quality when obtained from the former exclusively. Dried lavender flowers are said to yield from 1 to 1·5 per cent. of oil. According to Zeller, the fresh flowers yield 1·03, the dried 4·3, the whole fresh herb in flower 0·76 per cent. It is stated that the lavender produced by an acre of ground under cultivation will yield from 10 to 12 pounds of the oil. (*Pharm. Journ.*, Nov. 1864, p. 257.) The oil is very fluid, of a lemon-yellow colour, with the fragrance of the flowers, and an aromatic, burning taste. That met with in commerce has the sp. gr. 0·898 at 68° F., which is reduced to 0·877 by rectification (*Berzelius*), or 0·886 (*Buignet*). It is lævogyrate. According to Brande, the sp. gr. of the oil obtained from the whole herb is 0·9206. Alcohol of 0·830 dissolves oil of lavender in all proportions; that of 0·877, only 42 per cent. (*Berzelius.*) Proust states that, when allowed to stand in imperfectly stopped bottles, it lets fall a crystalline deposit, which often amounts to one-fourth of its weight. This has been found by M. Dumas to have the same point of volatilization and the same composition as the true camphor, but differs in the total want of rotatory power. (*Ibid.*, Juillet, 1863, p. 30.) It is said that the portion of oil first distilled is most fragrant, and is often kept separate, and sold at a higher price. According to M. Lallemand, oil of lavender consists chiefly of an oil isomeric with pure oil of turpentine, but contains acetic acid in combination, probably in the state of amylacetic ether. (*Journ. de Pharm.*, Avril, 1860, p. 290.) It is used chiefly as a perfume, though possessed of carminative and stimulant properties, and sometimes useful in cases of nervous languor and headache. The dose is from one to five drops.*

* *Cologne Water.* One of the Farinas, the noted manufacturers of Cologne water, the composition of which has been carefully kept secret by that family, is said recently to have published the following formula, as being that of the genuine perfume. "Take of Oil or

Oil of Spike is procured from the broad-leaved variety of lavender which grows wild in Europe, the *Lavandula Spica* of De Candolle. Its odour is less fragrant than that of common oil of lavender, and is somewhat analogous to that of oil of turpentine, with which it is said to be often adulterated. It is used by artists in the preparation of varnishes.

Off. Prep. Linimentum Camphoræ Compositum, *Br.;* Spiritus Ammoniæ Aromaticus, *U. S.;* Spiritus Lavandulæ; Spiritus Lavandulæ Compositus, *U.S.;* Tinctura Lavándulæ Composita, *Br.* W.

OLEUM MENTHÆ PIPERITÆ. *U.S., Br. Oil of Peppermint.*

"Mentha piperita. The Oil distilled from the fresh herb in flower." *Br.*

Peppermint varies exceedingly in the quantity of oil which it affords. Four pounds of the fresh herb yield, according to Baumé, from a drachm and a half to three drachms of the oil. Zeller gives as the product of the fresh herb from 0·37 to 0·68 per cent., of the dried 1·14 per cent. The yield is generally less than 1 per cent. This oil is largely distilled in the United States. It is of a greenish-yellow colour or nearly colourless, but becomes reddish by age. Its odour is strong and aromatic, its taste warm, camphorous, and very pungent, but succeeded, when air is admitted into the mouth, by a sense of coolness. Its sp. gr. is stated differently from 0·902 to 0·920; its boiling point at 365°. It is considerably lævogyrate. (*Buignet.*) Upon long standing it deposits a *stearoptene*, which, according to Kane, has the same composition as the oil, viz., $C_{21}H_{22}O_2$. Berzelius states that at 8° below zero the oil deposits small capillary crystals. These, which are called *peppermint camphor*, melt at 95° F., volatilize unchanged, and, when distilled with anhydrous phosphoric acid, yield a peculiar aromatic product, denominated *menthene*. (*Gmelin's Handbook*, xiv. p. 445.) This oil is frequently adulterated with alcohol, and occasionally, there is reason to believe, with oil of turpentine. This is detected by its odour, by its deficient solubility in cold alcohol, and by imparting the property of exploding with iodine. It is stated by the Messrs. Hotchkiss that, in much of the land under culture with peppermint in this country, other oil-producing plants are carelessly allowed to grow, which, being gathered and distilled with the peppermint, contaminate the product. (*Am. Journ. of Pharm.*, xxvii. 222.) Such impurities may be detected by the altered odour of the oil. When freshly prepared, it should volatilize completely from paper without leaving a mark, and, when dropped into alcohol of 85 per cent., should completely dissolve without agitation. (Bullock, *Ibid.*, Nov. 1859, p. 553.) Much of the oil used in the United States is produced in Michigan. (*Ibid.*, xxix. 312.)

Oil of peppermint is stimulating and carminative, and is much used in flatulence, nausea, spasmodic pains of the stomach and bowels, and as a corrigent or adjuvant of other medicines. The dose is from one to three drops, and is most conveniently given rubbed with sugar and then dissolved in water. The oil is frequently employed, dissolved in alcohol, in the form of *essence of peppermint*, which is an officinal preparation. (See *Spiritus Menthæ Piperitæ.*)

Off. Prep. Aqua Menthæ Piperitæ; Pilulæ Rhei Compositæ; Spiritus Menthæ Piperitæ; Trochisci Menthæ Piperitæ, *U. S.* W.

OLEUM MENTHÆ VIRIDIS. *U.S., Br. Oil of Spearmint.*

"Mentha viridis. The Oil distilled in England from the fresh herb in flower" *Br.*

Lavender 4 *ounces;* Purified Benzoin, Oil of Rosemary, each, 2 *ounces;* Stronger Alcohol 9 *gallons.* Dissolve the oils and benzoin in the alcohol; and to the solution add successively, of Oil of Neroli, Oil of the young orange denominated by the French Huile de Petits Grains, Oil of Lemons, each, 10·4 *ounces;* Oil of the Sweet Orange, Oil of the Lime, and Oil of Bergamot, each, 20·8 *ounces;* Tincture of the Flowers of the Rose Geranium *a sufficient quantity.* Macerate for some weeks, and introduce into flasks." (See *Am. Journ. of Pharm.*, July, 1864, p. 376.)—*Note to the twelfth edition.*

According to Lewis, ten pounds of spearmint yield an ounce of oil; by others the product is stated not to exceed one part from five hundred. The oil is largely distilled in this country. It is pale-yellow or greenish when recently prepared, but becomes red with age, and ultimately almost of a mahogany colour. Its flavour is analogous to that of the oil of peppermint, but less agreeable and less pungent. Its sp. gr. is stated differently from 0·914 to 0·975; its boiling point at 320°. Kane gives the formula $C_{35}H_{28}O$, as representing its composition. It is used for the same purposes as the oil of peppermint, in the dose of from two to five drops. An *essence of spearmint*, prepared by dissolving the oil in alcohol, is officinal. (See *Spiritus Menthæ Viridis.*)

Off. Prep. Aqua Menthæ Viridis; Spiritus Menthæ Viridis, *U. S.* W.

OLEUM MONARDÆ. *U. S. Oil of Horsemint.*

This is prepared by our distillers from the fresh herb of *Monarda punctata*. It has a reddish-amber colour, a fragrant odour, and a warm, very pungent taste. At 40° F., or lower, especially in the presence of moisture, it is gradually transformed by oxidation into a crystalline body, having the odour and taste of the oil. This appears to be analogous in constitution to camphor, being the oxide of a carbohydrogen radical ($C_{10}H_7$), three eqs. of which with one eq. of oxygen form the liquid oil. (C. T. Bonsall, *Am. Journ. of Pharm.*, xxv. 200.) It is now considered as identical with thymol, or camphor of the oil of thyme. (See *Oleum Thymi*, in Part I.) Applied to the skin, monarda oil is powerfully rubefacient, quickly producing heat, pain, redness, and even vesication. It has been employed externally in low forms of fever, cholera infantum, chronic rheumatism, and other affections in which rubefacients are indicated. In ordinary cases it should be diluted before being applied. It may be given internally as a stimulant and carminative, in the dose of two or three drops mixed with sugar and water. W.

OLEUM ORIGANI. *U. S.* 1850, *Ed. Oil of Origanum. Oil of Marjoram.*

This is obtained from the common marjoram, *Origanum vulgare*, and is frequently called *oil of marjoram*. Though it has been satisfactorily determined by Mr. Hanbury that the oil circulating in commerce by the name of oil of origanum is really obtained from *Thymus vulgaris* growing in the south of France, and on this account the proper oil of marjoram has been expunged from our Pharmacopœia, and its place supplied by the oil of thyme (see *Oleum Thymi* in Part I.), yet, as Origanum vulgare is a common plant, possessed of valuable aromatic properties, and readily yields its oil by distillation in the ordinary mode, and as there is no reason to suppose that the descriptions given by authors from whom we have quoted are not those of the genuine oil, it is deemed expedient to retain the oil in its old position, and to continue the description given of it in former editions. The plant varies exceedingly in the proportion of oil which it affords. The mean product may be stated at from four to six parts from a thousand. The recent oil, when properly prepared, is yellow; but, if too much heat is used in the distillation, it is said to be reddish, and it acquires the same tint by age. It may be obtained colourless by rectification. It has the odour of the plant, and a hot acrid taste. Kane gives its sp. gr. 0·867, its boiling point 354°, and its composition $C_{50}H_{40}O$. According to Lewis, its sp. gr. is 0·940, according to Brande 0·909. It is sometimes used as an external irritant, and to allay the pain of toothache, by being introduced, on lint or cotton, into the cavity of a carious tooth. It is little employed internally.

The *oil of sweet marjoram* (*Origanum Majorana*) is obtained from the plant by distillation, in the quantity of from 2·5 to 6 parts from 1000. It is of a lemon-yellow colour, light, and camphorous, and is said upon long standing to deposit a substance resembling camphor. It is not used in this country. W.

OLEUM PIMENTÆ. *U. S., Br. Oil of Pimento.*

"The Oil distilled in England from Pimento." *Br.*

The berries yield from 1 to more than 4 per cent. of oil, which, as found in the shops, is brownish-red, and has the odour and taste of pimento, though warmer and more pungent. It is said, when freshly distilled, to be colourless or yellowish. Nitric acid reddens it. Its sp. gr. is stated at 1·021, but varies. It consists, like oil of cloves, of two distinct oils, a lighter and heavier, the former of which comes over first in distillation. They may be separated by distilling the oil from caustic potassa. The light oil comes over, and the heavy remains combined with the potassa. The latter may be obtained by distilling the residue with sulphuric acid. The light oil is lighter than water, and is a pure carbohydrogen. The heavy has the acid property of forming crystalline compounds with the alkalies. They are analogous to the light and heavy oils of cloves. Indeed, the heavy has been found to be identical with the *eugenic acid* of that oil. (See *Oleum Caryophylli.*) The oil of pimento is given for the same purposes as the other stimulant aromatic oils. The dose is from three to six drops. W.

OLEUM ROSMARINI. *U. S., Br. Oil of Rosemary.*

"Rosmarinus officinalis. The Oil distilled in England from the flowering tops." *Br.*

The fresh leaves of rosemary yield, according to Baumé, 0·26 per cent. of oil; but the product is stated much higher by others. According to Brande, a pound of the fresh herb yields about a drachm of the oil, which is about 1 per cent.; and Zeller gives very nearly the same product for the dried herb. This oil is colourless, with an odour similar to that of the plant, though less agreeable. Its sp. gr. is said to be 0·911, but reduced to 0·8886 by rectification. Buignet gives the sp. gr. of the rectified oil 0·896, and states that it is moderately dextrogyrate. It is soluble in all proportions in alcohol of 0·830; but requires for solution at 64° forty parts of alcohol of 0·887. (*Berzelius.*) Kane gives its sp. gr. 0·897, its boiling point 365°, and its composition $C_{45}H_{38}O_2$. Kept in bottles imperfectly stopped, it deposits a *stearoptene* analogous to camphor, sometimes amounting, according to Proust, to one-tenth of the oil. Bucholz states that it affords camphor when digested with from one-half its weight to an equal weight of potassa, and distilled. It is said to be sometimes adulterated with oil of turpentine, which may be detected by mixing the suspected liquid with an equal volume of pure alcohol. The oil of rosemary is dissolved, and that of turpentine left. This oil is stimulant, but is employed chiefly as an ingredient of rubefacient liniments. The dose is from three to six drops.

A case of death is recorded, in a child four or five years old, from a mixture of six measures of this oil, and two of oil of wormseed, given in repeated doses of a tablespoonful. (*Am. Journ. of Pharm.*, xxiii. 286.)

Off. Prep. Linimentum Saponis; Spiritus Lavandulæ Compositus, *U. S.;* Spiritus Rosmarini, *Br.;* Tinctura Lavandulæ Composita, *Br.* W.

OLEUM RUTÆ. *Br. Oil of Rue.*

"Ruta graveolens. The Oil distilled in England from the fresh leaves and unripe fruit." *Br.*

Rue yields a very small proportion of a yellow or greenish oil, which becomes brown with age. According to Zeller, the product of the fresh herb is 0·28 per cent., of the seeds about 1 per cent. The oil has the strong unpleasant odour of the plant, and an acrid taste. Kane gives its sp. gr. 0·837, its boiling point 446°, and its composition $C_{28}H_{28}O_3$. Gregory considers it as hydrated oxide of rutyl or rutylic aldehyd ($C_{20}H_{19}O,HO = C_{20}H_{20}O_2$), associated with a carbohydrogen. (*Handbook of Organic Chemistry*, 4th ed., pp. 275 and 342.) According to Williams, the composition of the pure oxygenated oil is $C_{22}H_{22}O_2$, which is confirmed by Harbordt, who, by oxidizing it by means of chromic acid, ob-

tained caprinic acid, and concludes that its proper title is *methylo-caprinol*, and its rational formula $C_2H_3,C_{20}K_{19}O_2$. (See *Am. Journ. of Pharm.*, Jan. 1863, p. 34.) When treated with nitric acid, it yields, among other products, pelargonic acid, which is used in the preparation of a fruit essence, denominated *pelargonic ether*. (See *Fruit Essences*, in Part III.) It is stimulant and antispasmodic, and has been given in hysteria, convulsions, and amenorrhœa. The dose is from two to five drops. W.

OLEUM SABINÆ. *U. S.*, *Br.* *Oil of Savine.*

"The Oil distilled in England from fresh Savin." *Br.*

According to the more recent authorities, the proportion of volatile oil obtained from savine varies from less than 1 to 2·5 per cent. The oil is nearly colourless or yellow, limpid, strongly odorous, and of a bitterish, extremely acrid taste. Kane gives its sp. gr. 0·915, its boiling point 315°, and its composition $C_{10}H_8$, equivalent to that of oil of turpentine. According to Winckler, it is converted by sulphuric acid into an oil not distinguishable from that of thyme. (*Chem. Gaz.*, Jan. 1847, p. 11.) With iodine it becomes heated, detonates, and gives off yellow and violet-red vapours. (*Flaschoff.*) Distilled with 24 parts of water and 8 of chloride of lime, it evolves carbonic acid with effervescence, and yields *chloroform*. (*Gmelin's Handbook*, xiv. 310.) The oil of savine is stimulant, emmenagogue, and actively rubefacient, and may be given for the same purposes as the plant in substance. It has been much employed empirically in amenorrhœa, and with a view to produce abortion, and in some instances with fatal effects. The dose is from two to five drops. W.

OLEUM SASSAFRAS. *U. S.* *Oil of Sassafras.*

The proportion of oil yielded by the root of sassafras is variously stated from less than 1 to somewhat more than 2 per cent. The bark of the root, directed by the U. S. Pharmacopœia, would afford a larger amount. Very large quantities of the oil are distilled in Maryland, and sent to Baltimore for sale. The usual yield is said by Mr. Sharp to be one pound from three bushels of the root. From fifteen to twenty thousand pounds were sent annually, before the war, to the Baltimore market. (A. P. Sharp, *Am. Journ. of Pharm.*, Jan. 1863, p. 53.) The oil is of a yellow colour, becoming reddish by age. It has the fragrant odour of sassafras, with a warm, pungent, aromatic taste. It is among the heaviest of the volatile oils, having the sp. gr. 1·094, or 1·087 on the authority of Buignet, who states also that it is very slightly dextrogyrate. According to Bonastre it separates, by agitation with water, into two oils, one lighter, the other heavier than water. Berzelius states that the first is often nothing more than oil of turpentine existing as an adulteration in the oil of sassafras. Nitric acid colours it red, and fuming nitric acid inflames it more readily than most other oils. It has the property of dissolving caoutchouc. When kept for a long time it deposits transparent crystals, having the same odour as the liquid oil. By treating the oil with chlorine, neutralizing with lime, and distilling, a product is obtained identical in properties and composition with common camphor. (See *Am. Journ. of Pharm.*, xxvi. 166.) Mr. E. S. Wayne, of Cincinnati, has shown that the oil forms an insoluble compound with lead; a property which renders leaden vessels, or those containing lead, unsuitable recipients for it. (*Am. Journ. of Pharm.*, xxviii. 521.) Oil of sassafras is stimulant, carminative, and supposed to be diaphoretic; and may be employed for the same purposes as the bark from which it is derived. The dose is from two to ten drops.

Off. Prep. Syrupus Sarsaparillæ Comp., *U. S.*; Trochisci Cubebæ, *U. S.* W.

OLEUM SUCCINI RECTIFICATUM. *U. S.* *Rectified Oil of Amber.*

"Take of Oil of Amber *a pint;* Water *six pints.* Mix them in a glass retort, and distil until four pints of water have passed with the Oil into the re-

ceiver; then separate the Oil from the Water, and keep it in a well-stopped bottle." *U. S.*

For an account of the crude oil (*Oleum Succini*) the reader is referred to *Part I.* (page 578). By successive distillations oil of amber is rendered thinner and more limpid, till at length it is obtained colourless. The first portions which distil are less coloured than those which follow, and may be separated for keeping, while the remainder is submitted to another distillation. For practical purposes, however, the oil is sufficiently pure when once redistilled, as directed in the U. S. Pharmacopœia. As usually found in the shops, the rectified oil is of a light yellowish-brown or amber colour. When quite pure it is colourless, as fluid as alcohol, of the sp. gr. 0·758 at 75°, and boils at 186°. It has a strong, peculiar, unpleasant odour, and a hot, acrid taste. It imparts these properties in some degree to water, without being perceptibly dissolved. It is soluble in eight parts of alcohol of the sp. gr. 0·847 at 55°, in five parts of the sp. gr. 0·825, and in all proportions in absolute alcohol. The fixed oils unite with it. On exposure to the light and air, it slowly changes in colour and consistence, becoming ultimately black and solid. It appears, when quite pure, to be a carbohydrogen, consisting, according to Dr. Döpping, of 88·46 parts of carbon and 11·54 of hydrogen in 100. (*Chem. Gaz.*, Nov. 1845, p. 447.) It is said to be sometimes adulterated with oil of turpentine, which may be detected by passing muriatic acid gas through the suspected oil. If pure it will remain wholly liquid; while oil of turpentine, if present, will give rise to the formation of solid artificial camphor. (*Pharm. Journ.*, xiii. 292.)

Medical Properties and Uses. Rectified oil of amber is stimulant and antispasmodic, and occasionally promotes the secretions, particularly that of urine. It has been employed with advantage in amenorrhœa, and in various spasmodic and convulsive affections, as tetanus, epilepsy, hysteria, hooping-cough, and infantile convulsions from intestinal irritation, &c. The dose is from five to fifteen drops, diffused in some aromatic water by means of sugar and gum arabic. Externally applied the oil is rubefacient, and is considerably employed as a liniment in chronic rheumatism and palsy, and in certain spasmodic disorders, as hooping-cough and infantile convulsions. In the latter affection it should be rubbed along the spine, and was highly recommended by the late Dr. Joseph Parrish, mixed with an equal measure of laudanum, and diluted with three or four parts of olive oil and of brandy. W.

OLEUM TABACI. *U. S. Oil of Tobacco.*

"Take of Tobacco, in coarse powder, *twelve troyounces.* Put it into a retort of green glass, connected with a refrigeratory, to which a tube is attached for the escape of the incondensible products. Then, by means of a sand-bath, heat the retort gradually to dull redness, and maintain it at that temperature until empyreumatic oil ceases to come over. Lastly, separate the dark, oily liquid in the receiver from the watery portion, and keep it in a well-stopped bottle." *U. S.*

This is a black, thickish liquid, of a strong characteristic odour, identical with that of old tobacco pipes, and in no degree resembling that of undecomposed tobacco. It may be obtained colourless by rectification, but soon becomes yellowish and ultimately brown. It probably contains a portion of nicotia volatilized unchanged, and is a powerful poison, unfit for internal use, and when employed externally requiring much caution. Mixed with simple ointment or lard, in the proportion of twenty drops to an ounce, it has been used as an application to indolent tumours, buboes, ulcers, and obstinate cutaneous eruptions; but, in all cases where the cuticle is wanting, it should be employed with reserve, and its effects carefully watched. W

OLEUM VALERIANÆ. *U. S. Oil of Valerian.*

This was introduced for the first time as an officinal into the U. S Pharma-

copœia of 1850. It is obtained from the root of Valeriana officinalis by the usual process of distillation with water. According to Zeller, the dried root of the best quality yields 1·64 per cent. of the oil. Very good oil has been distilled from the root cultivated in this country. As first procured, it is of a pale-greenish colour, of the sp. gr. 0·934, with a pungent odour of valerian, and an aromatic taste. Upon exposure, it becomes yellow and viscid. It is a complex substance, containing 1. a carbohydrogen isomeric with pure oil of turpentine; 2. a small proportion of stearoptene, of an odour resembling that of camphor and pepper, and formed probably by the combination of water with the preceding constituent; 3. a peculiar oxygenated oil, called *valerol* ($C_{20}H_{12}O$, Kane's *Chemistry*), which, by the agency of the air, is converted into *valerianic* (*valeric*) *acid* and a resinous matter; and 4. valerianic acid, which always exists in the oil in small proportion, but is increased by exposure. The conversion of valerol into valerianic acid, through the agency of atmospheric oxygen, is very much promoted by the presence of caustic alkalies, which combine with the acid, when formed, to produce valerianates. Somewhat different views of the oil are given by M. Pierlot, who has investigated its nature. According to this chemist, the oil, whether fresh or old, always contains about 5 hundredths of valerianic acid, and, besides this, the two oils above referred to, namely, the carbohydrogen, which he names *valerene*, and the valerol, the formula of which he gives as $C_{24}H_{20}O_2$, and which becomes resinified by exposure to the air. He has concluded, moreover, that valerol cannot be changed into an acid by any known process. (See *Am. Journ. of Pharm.*, March, 1860, p. 142.) The oil of valerian exercises the same influence as the root on the nervous system, and is frequently administered as a substitute for it in the dose of four or five drops. W.

OLEORESINÆ.

Oleoresins.

The oleoresins, as a class of Preparations, were newly introduced into the U. S. Pharmacopœia at the late revision, having been previously considered with the Fluid Extracts. Their peculiarity is that they consist of principles, which, when extracted by means of ether, retain a liquid or semi-liquid state upon the evaporation of the menstruum, and at the same time have the property of self-preservation; differing in this respect from the fluid extracts, which require the presence of alcohol or sugar to prevent decomposition. They consist chiefly, as their name implies, of oil either fixed or volatile, holding resin and sometimes other active matter in solution. Their preparation is very simple, consisting in the exhaustion of the medicine employed with ether, by means of percolation, and the subsequent evaporation of the menstruum. In consequence of the great volatility of ether, it may in great measure be recovered by distillation, thus very materially diminishing the costliness of the process. It is proper not to continue the heat necessary for the distillation till the whole of the ether is driven over, lest, towards the close, a portion of the volatile matters also should pass, and the strength of the oleoresin be impaired. Hence, in every instance, the last portions of the menstruum are allowed to separate by spontaneous evaporation. W.

OLEORESINA CAPSICI. *U. S.* *Oleoresin of Capsicum.*

"Take of Capsicum, in fine powder, *twelve troyounces;* Ether *a sufficient quantity.* Put the Capsicum into a cylindrical percolator, press it firmly, and gradually pour Ether upon it until twenty-four fluidounces of filtered liquid have passed. Recover from this, by distillation on a water-bath, eighteen fluidounces of ether, and expose the residue, in a capsule, until the remaining ether has

evaporated. Lastly, remove, by straining, the fatty matter which separates on standing, and keep the Oleoresin in a well-stopped bottle." *U. S.*

The active principle of capsicum, called capsicin, is very soluble in ether, and is wholly extracted in the process. Its precise nature has not been determined; but, in the purest form in which it has been obtained, it is of a semi-liquid oleaginous consistence. After the concentration of the ethereal solution, a solid fatty matter separates on standing, but a portion of fixed oil probably still remains. The preparation is a very thick liquid, capable, however, of being dropped, of a dark reddish-brown colour, and, though opaque in mass, yet transparent in thin layers. It has not very decidedly the odour of capsicum, but to the taste is intensely pungent. It may be usefully employed to give locally stimulant properties to substances administered internally in a pilular form, in cases of gastric insensibility and excessive flatulence. Not more than a drop should be given at once, and that very much diluted, whether mixed with solids in the pill mass, or in liquid mixtures. It may be used also as a powerful rubefacient, diluted with olive oil or soap liniment. W.

OLEORESINA CUBEBÆ. *U. S.* EXTRACTUM CUBEBÆ FLUIDUM. *U. S.* 1850. *Oleoresin of Cubeb. Fluid Extract of Cubebs.*

"Take of Cubeb, in fine powder, *twelve troyounces;* Ether *a sufficient quantity.* Put the Cubeb into a cylindrical percolator, press it moderately, and gradually pour Ether upon it until twenty-four fluidounces of filtered liquid have passed. Recover from this, by distillation on a water-bath, eighteen fluidounces of ether, and expose the residue, in a capsule, until the remaining ether has evaporated. Lastly, keep the Oleoresin in a well-stopped bottle." *U. S.*

This *oleoresin* consists mainly of the volatile oil and resin, with a portion of the cubebin and waxy matter of the cubebs. The consistence differs with the character of the cubebs employed; its degree of fluidity being proportionate to the amount of volatile oil contained in the medicine. The colour is usually blackish-brown, with more or less of a greenish hue, according to the quantity of chlorophyll present, which varies with the character of the cubebs, and with that of the menstruum; pure ether extracting the green colouring matter preferably, while ordinary alcoholic ether extracts also the brown. Cubebs yield from one-eighth to one-fifth of their weight of fluid extract. The preparation deposits waxy matter and crystals of cubebin on standing; but its efficacy is probably not impaired. It was first introduced into use by Prof. Procter. (*Am. Journ. of Pharm.*, xviii. 168.) The dose is from five to thirty minims, which may be given suspended in water, or mixed with powdered sugar.

Off. Prep. Trochisci Cubebæ, *U. S.* W.

OLEORESINA FILICIS. EXTRACTUM FILICIS LIQUIDUM. *Br. Oleoresin of Fern. Liquid Extract of Fern Root.*

"Take of Fern Root, in coarse powder, *two pounds* [avoirdupois]; Ether *four pints* [Imperial measure], or *a sufficiency.* Mix the Fern Root with *two pints* [Imp. meas.] of the Ether; pack closely in a percolator; and add the remainder of the Ether at intervals, until it passes through colourless. Let the ether evaporate on a water-bath, or recover it by distillation, and preserve the oily extract." *Br.*

This is a new officinal of the British Pharmacopœia, and ought to have a place in our own. Though introduced in the Pharmacopœia among the Extracts, it yet by its character belongs so decidedly to the oleoresins, that we have deemed it expedient to give it this position, and to name it, in chief, *Oleoresin of Fern.* It is an ethereal extract of the Fern Root, consisting mainly of oily and resinous matter, and has been long known and much used on the Continent of Europe, under the name of *oil of fern*, in the treatment of the tape-worm. It is a thick, dark liquid, with the odour of fern, and a nauseous, bitterish, some-

what acrid taste. (See *Filix Mas*, in Part I.) It is believed to have all the anthelmintic powers of the male fern, and may be given in the dose of half a fluidrachm. W.

OLEORESINA LUPULINÆ. *U. S. Oleoresin of Lupulin.*

"Take of Lupulin *twelve troyounces;* Ether *a sufficient quantity.* Put the Lupulin into a narrow cylindrical percolator, press it firmly, and gradually pour Ether upon it until thirty fluidounces of filtered liquid have passed. Recover from this, by distillation on a water-bath, eighteen fluidounces of ether, and expose the residue, in a capsule, until the remaining ether has evaporated. Lastly, keep the Oleoresin in a wide-mouthed bottle, well stopped." *U. S.*

Lupulin yields its volatile oil and resin, as well as any other active principle it may contain, to ether, and the resulting oleoresin constitutes about three-eighths, or somewhat less than one-half of the original drug. It is of a very thick semi-fluid consistence, so thick indeed that it cannot be conveniently administered by drops. Its colour is almost black in mass, but a rich reddish-brown in thin layers. It has the odour and taste of lupulin, and possesses all its medical properties. The dose is from two to five grains, and may be most conveniently administered in the form of pill, made with powdered liquorice root, or other proper excipient. W.

OLEORESINA PIPERIS. *U. S.* EXTRACTUM PIPERIS FLUIDUM. *U. S.* 1850. *Oleoresin of Black Pepper. Fluid Extract of Black Pepper.*

"Take of Black Pepper, in fine powder, *twelve troyounces;* Ether *a sufficient quantity.* Put the Black Pepper into a cylindrical percolator, press it firmly, and gradually pour Ether upon it until twenty-four fluidounces of filtered liquid have passed. Recover from this, by distillation on a water-bath, eighteen fluidounces of ether, and expose the residue, in a capsule, until the remaining ether has evaporated, and the deposition of piperin in crystals has ceased. Lastly, separate the Oleoresin from the piperin by expression through a muslin strainer, and keep it in a well-stopped bottle." *U. S.*

A substance has long been in use under the name of *oil of black pepper*, consisting mainly of the volatile oil and resin of the pepper, and belonging, therefore, to the oleoresins. As usually found, it is almost black, and of a thickish consistence, and is a residue of the process for preparing piperin. The officinal oleoresin has the same general character, but is more fluid, and of more uniform strength, and should, therefore, be preferred. It contains almost all the volatile oil and acrid resin of black pepper, with little of the piperin; and, as the last-mentioned principle, when quite pure, is of doubtful efficacy, the extract may be considered as representing the virtues of the fruit. The colour is greener than that of the common oil of black pepper, and not so dark, owing to the fact that ether dissolves the green more readily than the brown colouring matter. A pound of black pepper yields about six drachms of the fluid extract, the dose of which, proportionate to the ordinary dose of pepper, would be one or two minims. It may be given in emulsion, or may be combined in small proportion with other substances in the form of pill. W

OLEORESINA ZINGIBERIS. *U. S. Oleoresin of Ginger.*

"Take of Ginger, in fine powder, *twelve troyounces;* Stronger Ether *twelve fluidounces;* Alcohol *a sufficient quantity.* Put the Ginger into a cylindrical percolator, press it firmly, and pour upon it the Stronger Ether. When this has been absorbed by the powder, add Alcohol until twelve fluidounces of filtered liquid have passed. Recover from this, by distillation on a water-bath, nine fluidounces of ether, and expose the residue, in a capsule, until the volatile part has evaporated. Lastly, keep the Oleoresin in a well-stopped bottle." *U. S.*

In the preparation of this oleoresin alcohol is used in connection with ether, but solely on the score of economy; as it is added in order to displace the ether,

and thus save an unnecessary expenditure of this more costly fluid. A little of the alcohol, no doubt, mixes with the ether at their surface of contact, but only a little; and the liquid which passes is mainly the ether loaded with the oleoresinous matter of the ginger. The whole of the virtues of the root are extracted in this preparation, as the residuary ginger is nearly or quite tasteless. The oleoresin constitutes about 5 per cent. of the dried root. It is the *piperoid of ginger* of M. Beral. (*Soubeiran's Trait. de Pharm.*, i. 371.) It is a clear dark-brown liquid, of a thick consistence, though capable of being dropped, with the flavour of ginger, and intensely pungent. Its dose should not exceed a minim, and should be much diluted when administered. W.

PILULÆ.

Pills.

These are small globular masses of a size convenient for swallowing. They are well adapted for the administration of medicines which are unpleasant to the taste or smell, or insoluble in water, and do not require to be given in large doses. Deliquescent substances should not be made into pills; and those which are efflorescent should be previously deprived of their water of crystallization. Care should also be taken not to combine materials, the mutual reaction of which may result in a change of form.

Some substances have a consistence which enables them to be made immediately into pills. Such are the softer extracts and certain gum-resins; and the addition of a little water to the former, and a few drops of spirit to the latter, will give them the requisite softness and plasticity, if previously wanting. Substances which are very soft, or in the liquid state, are formed into the pilular mass by incorporation with dry and inert powders, such as wheat flour, starch, and powdered gum arabic, or with crumb of bread. Powders must be mixed with soft, solid bodies, as extracts, confections, soap, &c., or with tenacious liquids, as syrup, molasses, honey, mucilage, or glycerin; and the last-mentioned substance has been especially recommended in connection with a little alcohol. (*Tichborne.*) Heavy metallic powders are most conveniently made into pills with the former; light vegetable powders with the latter. Mucilage is very often used; but pills made with it are apt when kept to become hard, and of difficult solubility in the liquids of the stomach, and, if metallic substances are mixed with it, the mass does not work well. A mixture of syrup and powdered gum arabic is not subject to the same inconveniences, and is an excellent material for the formation of pills. Honey has been highly recommended. Confection of roses and molasses are among the best excipients, when the pills are to be long kept. For the same purpose of keeping the pill soft, the addition of a small portion of some fixed oil or deliquescent salt has been recommended; and glycerin will probably answer still better. Many powders require only water. Such are all those which contain ingredients capable of forming an adhesive or viscid solution with that liquid. Care should always be taken that the matter added be not incompatible with the main constituents of the pill.

The materials should be accurately mixed together, and beat in a mortar till formed into a perfectly uniform and plastic mass. This should be of such a consistence that the pills may preserve their form, without being so hard as to resist the solvent power of the gastric liquors. As pills frequently become very hard by time, it is often convenient to keep the mass in a state fit to be divided when wanted for use. This may be done by wrapping it in bladders, putting it in covered pots, and occasionally moistening it as it becomes dry; or, more effectually, by keeping it in glass or well-glazed jars, accurately closed with varnished bladder.

The mass, having been duly prepared, is made into pills by rolling it with a

spatula, or with a flat, smooth piece of hard wood, into a cylinder of precisely the same thickness throughout, and of a length corresponding to the number of pills required. It is then divided as equally as possible by the hand, or more accurately by a machine made for the purpose.* The pills receive a spherical form by being rolled between the fingers. M. Miahle describes a little instrument for rolling pills, composed of two circular plates, one about 12, the other 6 inches in diameter; the former having a ledge at the border one-third of an inch high, the latter with a similar ledge, varying, according to the size of the pills, from less than a line to nearly two lines, and with a strap on the back by which it can be fitted to the hand. This is to be moved in a rotary manner upon the larger plate, holding the divided portions of the pill mass. (*Journ. de Pharm.*, 3*e sér.*, xvii. 218.) In order to prevent the adhesion of pills to one another, or to the sides of the vessel in which they may be placed, it is customary to agitate them with some dry powder, which gives them an external coating, that serves also to conceal their taste. For this purpose, carbonate of magnesia, powdered liquorice root, or starch may be used. Carbonate of magnesia is sometimes incompatible with one of the ingredients of the pills; and liquorice root is generally preferable, though it sometimes becomes mouldy with very damp pills. The powder of *lycopodium*, which has been long in use in Europe, is now considerably employed in this country, and is perhaps the best substance for the purpose; and it was formerly the custom to give the pill a coating of gold or silver leaf.†

It has been proposed by M. Garot to cover pills with gelatin, which answers the purpose of concealing their taste and odour, and counteracting deliquescence or chemical change from exposure to the air, without interfering with their solubility in the stomach. He dips each pill, sustained on the point of a pin, into melted gelatin, withdraws it with a rotary motion, then fixes the pin in a paste so as to allow the coating to dry in the air, and, having prepared about fifty pills in this way, proceeds to complete the operation by holding the pin in the flame of a taper so as to melt the gelatin near its point, and then withdrawing it from the pill so as to close up the orifice. The purest glue should be selected for this purpose, melted with the addition of two or three drachms of water to an ounce of the glue, and kept liquid by means of a salt-bath.

Another plan for attaining the same objects, less effectual, but more convenient than the above, is to introduce the pills into a spherical box, to drop on them enough syrup simply to moisten their surface, then to give a rotary movement to the box until the pills are uniformly covered, and finally to add by degrees a powder consisting of equal parts of gum, sugar, and starch, shaking the box with each addition, and continuing the process until nothing more will adhere to the pills. The investing material may be rendered agreeable to the taste and smell by aromatic additions, if deemed advisable. (*Journ. de Pharm.*, x. 32.) M. Calloud has found that a better powder for the purpose, because less disposed to attract moisture, is made by boiling one part of flaxseed and three parts of white sugar with sufficient water till a thick mucilage is formed, evaporating this carefully to dryness, and then pulverizing. (*Ibid.*, xxiii. 301.) The same writer has since suggested, as still more effective, a powder made by forming a mucilage with one part of tragacanth and two of water, pressing this through linen, mixing it with twenty parts of sugar of milk, spreading

* The common pill-machine is too well known to require description. In the *Am. Journ. of Pharm.* (xxiv. 315) the reader will find the description of a rotary pill-machine, calculated to prepare large numbers of pills in a short time; and in the same journal (xxvi. 118) of another, which is considered an improvement on the first.

† This mode of protecting pills is still practised to some extent; and Messrs. Parrish and Bakes have published their method of proceeding. It consists in agitating the pills, prepared without dusting powder, and with their surface still damp, along with gold or silver leaf, in a hollow spherical wooden box, made by turning two hemispheres out of hard wood, fitting each other, and provided with a short handle. (*Am. Journ. of Pharm.*, Jan. 1861, p. 2.)

the paste thus made in thin layers to dry, and then powdering. The pills may be simply moistened with water, and then shaken in the powder. M. Lhermite proposes first to agitate the pills in a mortar with a little concentrated solution of gum, and afterwards to put them into a box containing dry and very finely powdered sugar, to which a rotary motion is given. If the coating be not sufficiently thick, the process may be repeated. (*Ibid.*, xxv. 460)* Still another method, proposed by Mr. E. K. Durden, is to cover the pills with collodion, which completely conceals the taste. The solution employed by Mr. Durden had the sp. gr. 0·810; and two dippings give a sufficient coating. (See *Am. Journ. of Pharm.*, xxi. 183.) It is, however, yet to be determined whether a coating of collodion would yield readily to the solvent powers of the gastric juice. M. Blancard covers pills with a solution of Tolu balsam in ether; but Mr. H. C. Baildon objects to this, that it takes too long to dry, and suggests as a substitute a solution of a drachm of the balsam in three drachms of chloroform, which dries sufficiently in twenty minutes. (*Am. Journ. of Pharm.*, xxix. 350.) If old and solid Tolu balsam be selected, it will be less liable to the objection of drying slowly. A solution of mastic in ether has also been used, and is officinally employed in coating the U. S. pills of iodide of iron. The white of egg has been recommended for the same purpose. (*Ibid.*, March, 1862, p. 137.)

Pills which are to be long kept should be well dried, and put into bottles with accurately fitting stoppers. Though the U. S. Pharmacopœia, in almost every instance, orders the mass to be divided into pills; yet it should be understood rather as indicating the number of pills to be made from a certain quantity of the mass, when particular directions are not given by the physician, than as requiring the division to be made immediately after the materials have been mixed. It will be found convenient by the apothecary to retain a portion of the mass undivided, especially when it is desirable to keep the pills soft.†

The Pills formerly officinal, which have been omitted in the present U. S. and Br. Pharmacopœias, are the *Compound Pills of Aloes*, Lond., Dub.; the *Pills of Calomel and Opium*, Ed.; the *Compound Pill of Hemlock*, Lond.; the *Pills of Sulphate of Iron*, Ed.; those of *Mild Chloride of Mercury*, U. S., and of *Ipecacuanha with Squill*, Lond.; the *Opiate Pills of Lead*, Ed.; *Pills of Rhubarb and Iron*, Ed.; and the *Compound Pills of Storax*, Lond., Ed. W.

* The sugar coating of pills is now conducted upon a great scale by manufacturers, who send large quantities both of popular and officinal pills into the market thus protected. The process employed is similar to that of the confectioners in coating almonds. After having been thoroughly dried, the pills are put into a hemispherical tinned copper basin, which is suspended from the ceiling, and moved quickly backward and forward with an eccentric motion, so as to cause a constant attrition among the pills. First a little very thick syrup, or syrup of gum, is introduced in order to give a thin coating to their surface; and afterwards very finely powdered and very dry white sugar is sifted or thrown over them; the motion being constantly maintained. The sugar is fixed by the moist surface of the pills, and the coating made compact and smooth by the attrition. The process is aided by a gentle heat, arising from an open charcoal fire beneath; but the heat must be guarded, lest the pills be much softened, and thus lose their shape, and even discolour the coating. Dextrous manipulation is necessary in order that the process may succeed satisfactorily.—*Note to the twelfth edition.*

† *Granules.* Minute pills, scarcely larger than a pin's head, have been recently popular in France, under the name of granules; and their use has of late been introduced to some extent in the United States. They are generally used for the administration of very powerful medicines, as digitaline for instance, which is given in the dose of one-fiftieth of a grain. An objection to them is the great difficulty of securing an exactly equal amount of the medicine in each granule; and great care, therefore, is necessary, in their preparation, to guard against this danger. Like the pills, these also are prepared on the large scale, and like them are sugar coated. The process moreover for making them is somewhat similar. The mass is first divided by a hand machine so as to ensure uniformity of size, and the little particles are then coated. The details, however, of the proceeding, as well as of the apparatus employed, are kept secret.—*Note to the twelfth edition*

PILULÆ ALOËS. *U. S.* Pilula Aloes Barbadensis. *Br.* Pilula Aloes Socotrinæ. *Br. Pills of Aloes. Pill of Barbadoes Aloes. Pill of Socotrine Aloes.*

"Take of Socotrine Aloes, in fine powder, Soap, in fine powder, each, *a troy ounce*. Beat them together with water so as to form a pilular mass, to be divided into two hundred and forty pills." *U. S.*

"Take of Barbadoes Aloes, in powder, *two ounces* [avoirdupois]; Hard Soap, in powder, *one ounce* [avoird.]; Oil of Caraway *one fluidrachm;* Confection of Roses *one ounce* [avoird.]. Beat all together until thoroughly mixed." *Br.*

The British process for pill of Socotrine Aloes is the same, except that Socotrine is substituted for Barbadoes Aloes, and the volatile Oil of Nutmeg for that of Caraway.

The soap, in this formula, not only serves to impart a proper consistence to the aloes, but is thought to qualify its operation, and diminish its liability to irritate the rectum. Five of the U. S. pills, containing ten grains of aloes, may be given with a view to their purgative effect; but the preparation is usually employed as a laxative in habitual costiveness, in the quantity of one, two, or three pills, taken before breakfast or dinner, or at bedtime. The British pill is of very nearly the same strength. W.

PILULÆ ALOËS ET ASSAFŒTIDÆ. *U. S., Br. Pills of Aloes and Assafetida.*

"Take of Socotrine Aloes, in fine powder, Assafetida, Soap, in fine powder, each, *half a troyounce*. Beat them together with water so as to form a pilular mass, to be divided into one hundred and eighty pills." *U. S.*

"Take of Socotrine Aloes, in powder, Assafetida, Hard Soap, in powder, Confection of Roses, each, *an ounce*. Beat all together until thoroughly mixed." *Br.*

These pills are peculiarly adapted, by the stimulant and carminative properties of the assafetida, to cases of costiveness attended with flatulence and debility of the digestive organs. Each pill contains about four grains of the mass. From two to five may be given for a dose. W.

PILULÆ ALOËS ET MASTICHES. *U. S. Pills of Aloes and Mastic.*

"Take of Socotrine Aloes, in fine powder, a *troyounce and a half;* Mastic, in fine powder, Red Rose, in fine powder, each, *half a troyounce*. Beat them together with water so as to form a pilular mass, to be divided into four hundred pills." *U. S.*

Each of these pills contains about four grains of the mass, including the water employed, and nearly two grains of aloes. They are an imitation of Lady Webster's dinner pills, and one of them may be given as a laxative at bedtime, or before a meal. The mastic has probably little other effect than to impair the solubility of the aloes, and thus give it a still greater tendency to act on the lower bowels.* W.

* The following is the formula for the aloetic pills, usually called *dinner pills*, or *Lady Webster's pills*. They are the *pilulæ stomachicæ* of the fifth edition of the Paris Codex, A. D. 1758. Take of the best aloes six drachms; mastic and red roses, each, two drachms; syrup of wormwood sufficient to form a mass, to be divided into pills of three grains each. Common syrup may be substituted for syrup of wormwood. One or two of these pills, taken shortly before a meal, will usually produce one free evacuation.

The Philadelphia College of Pharmacy has adopted the following formulas for the compound aloetic preparations commonly called *Hooper's* and *Anderson's pills*.

"*Hooper's female pills.* ℞. Aloës Barbadensis ℥viij, Ferri Sulphatis Exsiccati ℥ij, ℈iss, *vel* Ferri Sulphatis Crystal. ℥iv, Extracti Hellebori ℥ij, Myrrhæ ℥ij, Saponis ℥ij, Canellæ in pulv. tritæ ℥j, Zingiberis in pulv. trit. ℥j.—Beat them well together into a mass with

PILULÆ ALOES ET MYRRHÆ. *U. S., Br. Pills of Aloes and Myrrh*

"Take of Socotrine Aloes, in fine powder, *two troyounces;* Myrrh, in fine powder, *a troyounce;* Saffron, in fine powder, *half a troyounce;* Syrup *a sufficient quantity.* Beat the whole together so as to form a pilular mass, to be divided into four hundred and eighty pills." *U. S.*

"Take of Socotrine Aloes *two ounces;* Myrrh *one ounce;* Saffron, dried, *half an ounce;* Confection of Roses *two ounces and a half.* Triturate the Aloes, Myrrh, and Saffron together, and sift; then add the Confection of Roses, and beat together into a uniform mass." *Br.*

This composition has been long in use, under the name of *Rufus's pills.* It is employed, as a warm stimulant cathartic, in general debility attended with constipation, and retention or suppression of the menses. From three to six pills, or from ten to twenty grains of the mass may be given for a dose. W.

PILULÆ ANTIMONII COMPOSITÆ. *U. S.* PILULA CALOMELANOS COMPOSITA. *Br. Compound Pills of Antimony. Compound Calomel Pill. Plummer's Pills.*

"Take of Sulphurated Antimony, Mild Chloride of Mercury, each, *one hundred and twenty grains;* Guaiac, in fine powder, Molasses, each, *half a troyounce.* Rub the Sulphurated Antimony first with the Mild Chloride of Mercury, and afterwards with the Guaiac and Molasses, so as to form a pilular mass, to be divided into two hundred and forty pills." *U. S.*

"Take of Calomel, Sulphurated Antimony, each, *one ounce* [avoirdupois]; Guaiac Resin, in powder, *two ounces* [avoird.]; Castor Oil *one fluidounce.* Triturate the Calomel with the Antimony, then add the Guaiac Resin and Castor Oil, and beat the whole into a uniform mass." *Br.*

We prefer the title "compound calomel pill" of the British Pharmacopœia; as, though not scientific, it is not liable to any mistake, and is most expressive of the quality of the medicine. The antimonial employed, though under a different name, is identical with the old U. S. precipitated sulphuret. According to Vogel, a reaction takes place between the calomel and sulphuret of antimony, resulting in the production of chloride of antimony and sulphuret of mercury. (*Annal. der Pharm.*, xxviii. 236.) The preparation was originally introduced to the notice of the profession by Dr. Plummer, who found it useful as an alterative, and upon whose authority it was at one time much employed under the name of *Plummer's pills.* The combination is well adapted to the treatment of chronic rheumatism, and of scaly and other eruptive diseases of the skin, especially when accompanied with a syphilitic taint. Six grains of the U. S. preparation, and five of the British contain about one grain of calomel, and each U. S. pill about half a grain. One to two pills or more may be given morning and evening. W.

PILULÆ ASSAFŒTIDÆ. *U. S. Pills of Assafetida.*

"Take of Assafetida *a troyounce and a half;* Soap, in fine powder, *half a troyounce.* Beat them together with water so as to form a pilular mass, to be divided into two hundred and forty pills." *U. S.*

Each of these pills contains three grains of the gum-resin. They are a convenient form for administering assafetida, the unpleasant odour and taste of which render it very offensive in the liquid state. W.

water, and divide into pills, each containing two and a half grains." (*Journ. of the Phil. Col. of Pharm.*, v. 25.)

"*Anderson's Scots' pills.* ℞. Aloës Barbadensis ℥xxiv, Saponis ℥iv, Colocynthidis ℥j, Gambogiæ ℥j, Olei Anisi f℥ss. Let the aloes, colocynth, and gamboge be reduced to a very fine powder; then beat them and the soap with water into a mass, of a proper consistence to divide into pills, each containing three grains." (*Ibid.*)

PILULA CAMBOGIÆ COMPOSITA. *Br. Compound Pill of Gamboge.*

"Take of Gamboge, Barbadoes Aloes, Aromatic Powder, each, *one ounce*. Hard Soap, in powder, *two ounces;* Syrup *a sufficiency.* Pulverize the Gamboge and Aloes separately, mix them with the Aromatic Powder, add the Soap and afterwards the Syrup; and beat the whole into a uniform mass." *Br.*

This is an active purgative pill, and may be given in the dose of ten or fifteen grains. The formula is that of Dr. George Fordyce simplified. W.

PILULÆ CATHARTICÆ COMPOSITÆ. *U. S. Compound Cathartic Pills.*

"Take of Compound Extract of Colocynth *half a troyounce;* Extract of Jalap, in fine powder, Mild Chloride of Mercury [calomel], each, *one hundred and eighty grains:* Gamboge, in fine powder, *forty grains.* Mix the powders together; then with water form a pilular mass, to be divided into one hundred and eighty pills." *U. S.*

This cathartic compound was first made officinal in the second edition of the U. S. Pharmacopœia. It was intended to combine smallness of bulk with efficiency and comparative mildness of purgative action, and a peculiar tendency to the biliary organs. Such an officinal preparation was much wanted in this country, in which bilious fevers, and other complaints attended with congestion of the liver and portal circle generally, so much abound. The object of smallness of bulk is accomplished by employing extracts and the more energetic cathartics; that of a peculiar tendency to the liver, by the use of calomel; and that of efficiency with mildness of operation, by the union of several powerful purgatives. It is a fact, abundantly proved by experience, that drastic cathartics become milder by combination, without losing any of their purgative power. Nor is it difficult, in this case, to reconcile the result of observation with physiological principles. Cathartic medicines act on different parts of the alimentary canal and organs secreting into it. In small doses, both the irritation which they occasion and their purgative effect are proportionably lessened. If several are administered at the same time, each in a diminished dose, it is obvious that the combined purgative effect of all will be experienced; while the irritation, being feeble in each part affected, and diffused over a large space, will be less sensible to the patient, and will more readily subside. In the compound cathartic pills, most of the active purgatives in common use are associated together in proportions corresponding with their respective doses, so that an excess of any one ingredient is guarded against, and violent irritation from this cause prevented. The name of the preparation may at first sight seem objectionable, as it might be applied to any compound pills possessing cathartic properties; but, when it is considered that the ingredients cannot all be expressed in the title, that no one is sufficiently prominent to give a designation to the whole, and that the preparation is intended as the representative of numerous cathartics, and calculated for a wide range of application, the name will not be considered an inexcusable deviation from ordinary medical nomenclature. It is highly important, for the efficiency of these pills, that they be prepared in exact compliance with the directions, and that the *compound extract of colocynth* and the *extract of jalap* used be of good quality. When they fail, the result is generally ascribable to the substitution of jalap for the extract, or to the use of a compound extract of colocynth made with nearly inert scammony, inferior aloes, and insufficient colocynth, and altogether badly prepared.

Three of the pills, containing $10\frac{2}{3}$ grains of the mass, are a medium dose for an adult. In this quantity are four grains of compound extract of colocynth, three of extract of jalap, three of calomel, and two-thirds of a grain of gamboge. A single pill will generally be found to operate as a mild laxative. In a full

dose, the preparation acts vigorously on the bowels, producing bilious stools, generally without much pain or disorder of the stomach. It may be employed in most instances where a brisk cathartic is required; but is particularly applicable to the early stages of bilious fevers, to hepatitis, jaundice, and all those derangements of the alimentary canal, or of the general health, which depend on congestion of the portal circle. W.

PILULA COLOCYNTHIDIS COMPOSITA. *Br.* *Compound Pill of Colocynth.*

"Take of Colocynth, in powder, *one ounce;* Barbadoes Aloes, in powder, *two ounces;* Scammony, in powder, *two ounces;* Sulphate of Potash, in powder, *a quarter of an ounce;* Oil of Cloves *two fluidrachms;* Distilled Water *a sufficiency.* Mix the Powders, add the Oil of Cloves, and beat into a mass with the aid of Water." *Br.* The ounce employed is the avoirdupois ounce.

This is not, like the late London pills of the same name, merely another form of the compound extract of colocynth, though containing essentially the same materials; one great difference being that colocynth and aloes are used in substance in the pill, instead of in the state of extract. The present British preparation is that of the late Edinburgh Pharmacopœia slightly altered. Sulphate of potassa is used to promote the more complete division of the aloes and scammony. The preparation is actively cathartic in the dose of from five to twenty grains. W.

PILULA COLOCYNTHIDIS ET HYOSCYAMI. *Br.* *Pill of Colocynth and Hyoscyamus.*

This is directed in the British Pharmacopœia to be prepared in the same manner as the Compound Pill of Colocynth, except that *three ounces* of Extract of Hyoscyamus are taken in addition to the other ingredients, and added along with the oil of cloves to the mixed powders.

This is an old officinal of the Edinburgh College. It is asserted that the compound pill and compound extract of colocynth are almost entirely deprived of their griping tendency by combination, as above, with extract of hyoscyamus, without losing any of their purgative power. The dose is from five to twenty grains. W.

PILULÆ COPAIBÆ. *U. S.* *Pills of Copaiba.*

"Take of Copaiba *two troyounces;* Magnesia, recently prepared, *sixty grains.* Mix them together, and set the mixture aside until it concretes into a pilular mass, to be divided into two hundred pills." *U. S.*

When copaiba is mixed with pure magnesia, it gradually loses its fluidity, forming at first a soft tenacious mass, and ultimately becoming dry, hard, and brittle. The quantity of magnesia, and the length of time requisite for this change, vary with the condition of the copaiba; being greater in proportion to the fluidity of this substance, or, in other words, to its amount of volatile oil. The quantity of magnesia directed by the Pharmacopœia, one-sixteenth of the weight of the copaiba, is sufficient to solidify the latter, as it is often found in the shops, in the course of six or eight hours; but, when the copaiba is fresh, or has been kept in closely stopped bottles, and retains, therefore, nearly the whole of its oil, it is necessary either to augment the proportion of magnesia, or to expose the mixture for a much longer time, or to diminish the volatile oil of the copaiba by evaporation. The magnesia combines chemically with the *capaivic acid* or hard resin, but, in relation to the volatile oil, acts merely as an absorbent; for, when the solidified mass is submitted to the action of boiling alcohol, a part is dissolved, abandoning the magnesia with which it was mixed, while the resin, combined with another portion of the earth, remains undissolved. Varieties of copaiba, therefore, are solidifiable by magnesia, directly in proportion to the hard resin they contain, and inversely in proportion to the volatile

oil; the soft resin being indifferent. According to Guibourt, copaiba, not solidifiable by magnesia, may be made so by adding one-sixth of Bordeaux or common European turpentine. The magnesia employed should not have been allowed to become hydrated by exposure to a moist air or otherwise. In the preparation of the pills of copaiba, care should be taken to divide the mass before it has become too hard. The advantage of this preparation is, that the copaiba is brought to the state of pill with little increase of bulk. Each pill contains nearly five grains of copaiba, and from two to six may be taken for a dose twice or three times a day.

Hydrate of lime produces the same effect as magnesia, and, as stated by M. Thierry, in a shorter time, if employed according to his formula. He takes 15 parts of copaiba and 1 part of slaked lime, mixes them in a marble mortar, transfers the mixture to an open vessel, places this upon a sand-bath, and sustains the heat for four hours, occasionally stirring. The hydrate of lime must have been freshly prepared from recently burnt lime. The mixture loses only a twenty-fourth of its weight, which is chiefly the water of the hydrate. (*Journ. de Pharm.*, 3*e sér.*, i. 310.)

Pills may also be made by incorporating vegetable powders with copaiba so as to bring it to the proper consistence; but this method has the inconvenience of greatly increasing the bulk. Spermaceti and wax have been proposed as excipients; and the latter, which was originally suggested by J. F. Simon, is recommended by Mr. Maisch as retaining all the volatile oil, and, with some vegetable powder, forming a mass that will retain its plasticity for years. One part, each, of wax, copaiba, and vegetable powder will answer the purpose, when the copaiba does not contain more than 50 per cent. of volatile oil; but if richer than this, it will require more of the excipient. To prepare the pills, melt the wax at the lowest possible heat, then gradually add the copaiba, and lastly incorporate some vegetable powder, as pulverized liquorice root, for example, with the other ingredients. (See *Am. Journ. of Pharm.*, Jan. 1863, p. 17.) W.

PILULÆ FERRI CARBONATIS. *U. S.*, *Br.* *Pills of Carbonate of Iron. Vallet's Ferruginous Pills.*

"Take of Sulphate of Iron *eight troyounces;* Carbonate of Soda *nine troyounces;* Clarified Honey *three troyounces;* Sugar, in coarse powder, *two troyounces;* Boiling Water *two pints;* Syrup *a sufficient quantity.* Dissolve the salts separately, each in a pint of the Water, a fluidounce of Syrup having been previously added to each pint. Mix the two solutions, when cold, in a bottle just large enough to hold them, close it accurately with a stopper, and set it by that the carbonate of iron may subside. Pour off the supernatant liquid, and, having mixed water, recently boiled, with Syrup in the proportion of a pint to the fluidounce, wash the precipitate with the mixture until the washings no longer have a saline taste. Place the precipitate on a flannel cloth to drain, and, having expressed as much of the water as possible, mix it immediately with the Clarified Honey and Sugar. Lastly, by means of a water-bath, evaporate the mixture, constantly stirring, until it is brought to the weight of eight troyounces." *U. S.*

"Take of the Saccharated Carbonate of Iron *one ounce;* Confection of Red Roses *a quarter of an ounce.* Beat them into a uniform mass." *Br.*

The effect of saccharine matter in protecting iron from oxidation has been explained under the heads of *Ferri Carbonas Saccharata* and *Syrupus Ferri Iodidi.* The *U. S.* pill of carbonate of iron is another example of a ferruginous preparation, in which the iron is protected from further oxidation by the same means. The salts employed are the same as those used for obtaining the officinal subcarbonate of iron; but, in forming that preparation, the carbonate which is at first precipitated absorbs oxygen, and loses nearly all its carbonic acid in the processes of washing and drying. When, however, as in the U. S. formula above

given, the reacting salts are dissolved in weak syrup instead of water, and the washing is performed with weak syrup also, the absorption of oxygen and loss of carbonic acid, during the separation of the precipitate, are almost completely prevented. It only remains, therefore, to preserve it unaltered, and to bring it to the pilular consistence, and this is effected by admixture with honey and sugar, and evaporation by means of a water-bath. It is essential to the success of this process, that the sulphate of iron should be pure; otherwise some sesquioxide will be present in the product. The process is that of M. Vallet, of Paris, after whom the preparation is popularly called. The present U. S. process differs from that of 1850, in boiling the water for washing so as to expel the air, and in evaporating to a definite weight at the close, instead of to a proper consistence as before directed; both of which changes are improvements suggested by Dr. Squibb. (*Proceed. of Am. Pharm. Assoc.*, 1858, p. 426.) The British pill of carbonate of iron is made from the saccharine carbonate, which is brought to the pilular consistence by being mixed with conserve of roses. This mode of making it is inferior to that of Vallet; for, in the first place, the saccharine carbonate is admitted to contain sesquioxide of iron, and, secondly, conserve of roses, while it is a less efficient preservative of the pilular mass than honey and sugar, will, through its tannic acid, form an inky compound with the ferruginous sesquioxide. (See *Ferri Carbonas Saccharata.*)

Properties. The U. S. preparation is in the form of a soft pilular mass, of a dark greenish-gray colour, becoming black on exposure, and with a strong ferruginous taste. When carefully prepared, it is wholly and readily soluble in acids. It contains nearly half its weight of carbonate of protoxide of iron. The corresponding pill, obtained from the saccharine carbonate, may be supposed to contain one-third of ferruginous matter.

Medical Properties. The U. S. pill of carbonate of iron, or Vallet's ferruginous mass, is admirably adapted to cases in which chalybeate preparations are indicated. It is considered particularly useful in chlorosis, amenorrhœa, and other female complaints, and appears to act favourably by increasing the colouring matter of the blood, causing the capillary system to become more fully injected, and the lips to assume a redder colour. It may be given in divided doses to the extent of from ten to thirty grains in the course of the day, and continued for a month or six weeks, if improvement take place. As the mass is not divided in the U. S. formula, it is necessary in prescription to indicate the weight of each pill, which may vary from three to five grains, according to the views of the prescriber. There is little doubt that, when the alterative effects of iron are indicated, Vallet's preparation is one of the best that can be employed. Its chief merits are its unchangeableness and ready solubility in acids. For further information respecting it, see the favourable report made on Vallet's pills to the French Royal Academy of Medicine, in 1837, by M. Soubeiran, republished in the *Am. Journ. of Pharm.* (x. 244), and the paper on carbonate of iron by Professor Procter, in the same journal (x. 272).

Blaud's ferruginous pills, celebrated in France as a remedy in chlorosis, are prepared from equal weights of sulphate of iron and carbonate of potassa, made into a pilular mass with mucilage of tragacanth and powdered liquorice root. They contain, as the result of the double decomposition, carbonate of protoxide of iron and sulphate of potassa. B.

PILULÆ FERRI COMPOSITÆ. *U. S. Compound Pills of Iron.*

"Take of Myrrh, in fine powder, *one hundred and twenty grains;* Carbonate of Soda, Sulphate of Iron, each, *sixty grains;* Syrup *a sufficient quantity.* Rub the Myrrh, first with the Carbonate of Soda, and afterwards with the Sulphate of Iron, until they are thoroughly mixed; then beat them with Syrup so as to form a pilular mass, to be divided into eighty pills." *U. S.*

This preparation is closely analogous to the Mistura Ferri Compositа in pro-

perties and composition. It is a good emmenagogue and antihectic tonic. As its peculiar advantages depend upon the presence of carbonate of protoxide of iron, which speedily changes into the sesquioxide on exposure, it is proper that only so much of the mass should be prepared as may be wanted for immediate use. It is said that the iron will be better preserved in the state of protoxide, if, instead of mixing the ingredients as directed in the Pharmacopœia, the operator should first dissolve the sulphate of iron, finely powdered, in the syrup, with a moderate heat, then add the carbonate of soda, stirring till they are thoroughly mixed, and lastly incorporate the myrrh. From two to six pills may be given at a dose three times a day. W.

PILULÆ FERRI IODIDI. *U. S.* Pilula Ferri Iodidi. *Br. Pills of Iodide of Iron.*

"Take of Iodine *half a troyounce;* Iron, in the form of wire and cut in pieces, *one hundred and twenty grains;* Sugar, in fine powder, *a troyounce;* Marshmallow, in fine powder, *half a troyounce;* Gum Arabic, in fine powder, Reduced Iron, each, *sixty grains;* Water *ten fluidrachms.* Mix the Iodine with a fluidounce of the Water in a thin glass bottle, add the Iron, and shake them together until a clear, green solution is obtained. Mix the Powders in a small porcelain capsule, and filter upon them, through a small filter, first the solution previously heated, and afterwards the remainder of the Water in order to wash the filter. Then, by means of a water-bath, with constant stirring, evaporate the whole to a pilular consistence, and divide the mass into three hundred pills.

"Dissolve sixty grains of Balsam of Tolu in a fluidrachm of Ether, shake the pills with the solution until they are uniformly coated, and put them on a plate to dry, occasionally stirring them until the drying is completed. Lastly, keep the pills in a well-stopped bottle.

"These pills are devoid of the smell of iodine; and distilled water, rubbed with them and filtered, does not colour solution of starch, or gives it only a slight blue tint." *U. S.*

"Take of Fine Iron Wire *forty grains;* Iodine *eighty grains;* Refined Sugar, in powder, *seventy grains;* Liquorice Root, in powder, *one hundred and forty grains;* Distilled Water *fifty minims.* Agitate the Iron with the Iodine and Water in a strong stoppered ounce phial, until the froth becomes white. Pour the fluid upon the Sugar in a mortar, triturate briskly, and gradually add the Liquorice." *Br.*

The pills of iodide of iron were introduced, as a new officinal, into the U. S. Pharmacopœia at the revision of 1850. The U. S. pills are formed on the plan proposed by Prof. Procter, in imitation of *Blancard's pills* (*Am. Journ. of Pharm.*, May, 1860), and are much superior to those made by the U. S. process of 1850, or by that of the British Pharmacopœia. The iodine and iron unite directly to form the iodide of iron in solution, which is protected against the oxidizing influence of the air by the sugar and reduced iron into which the solution is dropped, while the marshmallow and gum serve to give due consistence and plasticity to the pilular mass. The pills are still further protected from the air by the impervious coating of balsam of Tolu, which readily yields to the softening and solvent properties of the gastric liquids. The great disadvantage of the pill of iodide of iron, as ordinarily prepared, is that it will not keep; crumbling by time and exposure, and evolving iodine in consequence of the oxidation of the iron. The preparation, made according to the U. S. formula, has stood the test of time; and we have seen pills prepared four years since, which exhibit no signs of change. Each pill contains about a grain of iodide of iron and one-fifth of a grain of reduced iron. The therapeutic uses of this preparation are the same as those of iodide of iron. (See *Ferri Iodidum.*) B.

PILULÆ GALBANI COMPOSITÆ. *U. S.* PILULA ASSAFŒTIDÆ COMPOSITA. *Br. Compound Pills of Galbanum. Compound Pill of Assafetida.*

"Take of Galbanum, Myrrh, each, *three hundred and sixty grains;* Assafetida *one hundred and twenty grains;* Syrup *a sufficient quantity.* Beat them together so as to form a pilular mass, to be divided into two hundred and forty pills." *U. S.*

"Take of Assafetida, Galbanum, and Myrrh, each, *two ounces;* Treacle *an ounce.* Heat all together in a capsule by means of a steam or water bath, and stir the mass until it assumes a uniform consistence." *Br.*

This compound is given as an antispasmodic and emmenagogue in chlorosis and hysteria. The dose is from ten to twenty grains. W.

PILULÆ HYDRARGYRI. *U. S.* PILULA HYDRARGYRI. *Br. Pills of Mercury. Blue Pill.*

"Take of Mercury *a troyounce;* Confection of Rose *a troyounce and a half;* Liquorice Root, in fine powder, *half a troyounce.* Rub the Mercury with the Confection until the globules cease to be visible; then add the Liquorice Root, and beat the whole into a pilular mass, to be divided into four hundred and eighty pills." *U. S.*

The *British* process is the same with the above, one-half only of the quantity of materials being used, and no division of the mass into pills directed.

This preparation is generally known by the name of *blue pill* or *blue mass.* The mercury constitutes one-third of the mass; and consequently the pill of our Pharmacopœia, weighing three grains, contains one grain of the metal.

The precise condition of the mercury in this preparation is somewhat uncertain. By far the greater portion is in a state of minute mechanical division, and not chemically altered. Some maintain that the whole of the metal is in this state, others, that a small portion is converted during the trituration into the protoxide, and that this is the ingredient upon which the activity of the pill depends. The supposed oxidation is attributed partly to the influence of the air upon the surface of the metal, greatly extended by the separation of its particles, partly to the action of the substance used in the trituration. If the mercury be not oxidized during the trituration, there can be little doubt that it becomes so to a slight extent by subsequent exposure. The obvious changes which the mass undergoes by time can be explained in no other way; and protoxide of mercury is asserted to have been actually extracted from old mercurial pill. Nevertheless, it scarcely admits of dispute, that the metal, quite independently of oxidation out of the body, is capable of producing the peculiar mercurial effects when introduced into the stomach, probably undergoing chemical changes there. According to M. Mialhe, mercury is slowly converted into corrosive sublimate in the stomach, under the combined agency of air and chloride of sodium. All agree that the efficacy of the preparation is proportionate to the extinction of the mercury, in other words, to the degree in which the metallic globules disappear. This extinction may be effected by trituration with various substances; and manna, syrup, honey, liquorice, mucilage, soap, guaiac, and extract of dandelion have been recommended, among others, for this purpose; but the confection of roses has been adopted in all the Pharmacopœias, as less liable to objection than any other. The mercury is known to be completely extinguished, when, upon rubbing a small portion of the mass with the end of the finger upon a piece of paper or glass, no globules appear. Powdered liquorice root is added in order to give due consistence to the mass. Some prefer for the purpose powdered marshmallow root. Mr. W. W. Stoddart has found that the extinguishment of the mercury, in the officinal process, is very much hastened by rubbing it first with the *powdered liquorice root,* moistened with a little dis-

tilled water or rose water, and afterwards incorporating the confection. (*Am Journ. of Pharm.*, xxviii. 162.) As the trituration requires to be long continued, and renders the process very laborious, it is customary to prepare the mass by machinery. At Apothecaries' Hall, in London, the trituration is effected by the agency of steam. The machine there employed consists of "a circular iron trough for the reception of the materials, in which revolve four wooden cylinders, having also a motion on their axis." A machine for preparing blue mass, capable of being worked by the hand or by steam-power, has been invented by Mr. J. W. W. Gordon, of Baltimore, and, having been found to answer well, is in extensive use. It is described and figured in the *American Journal of Pharmacy* (xxi. 6). We have already referred, under *Hydrargyrum cum Cretâ*, to another ingenious apparatus invented by Dr. Squibb, by which the extinguishment of mercury is very satisfactorily effected.* Formerly much of the blue mass used in this country was imported; but at present the market is chiefly supplied by our own druggists. The preparation slowly changes colour upon being kept, assuming an olive and sometimes even a reddish tint, in consequence, probably, of the further oxidation of the mercury.†

Medical Properties and Uses. These pills are among the mildest of the mercurials, being less liable than most others to act upon the bowels, and exercising the peculiar influence of the remedy upon the system with less irritation. They are much employed for producing the sialagogue and alterative action of mercury. For the former purpose, one pill may be given two or three times a day; and in urgent cases the dose may be increased. Even this preparation sometimes disturbs the bowels. It should then be given combined with a little opium, or in very minute doses, as half a grain or a grain of the mass, repeated every hour or two through the day, so as to allow of its absorption before a sufficient quantity has been administered to act as an irritant. With a view to the alterative effect upon the digestive organs, one pill may be given every night, or every other night, at bedtime, and followed in the morning, if the bowels should not be opened, by a small dose of laxative medicine. From five to fifteen grains of the mass are occasionally given as a cathartic, in cases requiring a peculiar impression upon the liver; but, when used for this purpose, it should always either be combined with or speedily followed by a more certain purgative. The *blue mass* may often be administered with advantage, suspended in water by the intervention of thick mucilage; and it forms an excellent addition to the chalk

* Mr. James Beatson, apothecary of the U. S. Naval Hospital at New York, found great advantage in the following mode of preparing the mercurial pill, which, while much easier than the officinal method, yields the same results. Instead of mixing the mercury with the confection, he first rubs it with the honey directed in the preparation of the confection, until the globules disappear, then adds the heated rose water and sugar, and lastly the powdered red roses and liquorice root in succession, all in the officinal proportions. For the quantity of the material directed in the U. S. process for confection of roses, he employs 32 ounces of mercury. (*Am. Journ. of Pharm.*, xxiv. 204.)

† The mercurial pill is very apt to contain less than the due proportion of the metal. This was frequently the case with the mass as formerly imported. The fraud may be detected by the following plan of estimating the proportion of mercury, suggested by Prof. Reid, of New York, and modified by a committee of the Philadelphia College of Pharmacy. A certain weight of the mercurial pill, say fifty grains, is mixed with about one-fourth of its weight of iron filings, and introduced into a small green glass bulb, at the end of a somewhat curved tube, the open extremity of which is inserted, through a cork, into alcohol, contained in a broad-mouthed glass vial; another tube, open at both ends, passing through the cork in order to permit the escape of uncondensed gases. Heat is then applied to the bulb by means of a spirit-lamp, is gradually increased until the glass becomes red hot, and continued for an hour. The alcohol in the vial dissolves the empyreumatic products, and, by being allowed to rise in the tube, and then expelled, serves to wash out any mercury that may be condensed upon its sides. The alcohol is poured off from the condensed mercury, which is then washed with fresh alcohol, dried, and weighed. (See *Am. Journ. of Pharm.*, xvii. 151 and 309.)

mixture in diarrhœa, particularly that of children, when the biliary secretion is deficient, or otherwise deranged.* W.

PILULÆ OPII. *U. S. Pills of Opium.*

"Take of Opium, in fine powder, *sixty grains;* Soap, in fine powder, *twelve grains.* Beat them together with water so as to form a pilular mass, to be divided into sixty pills." *U. S.*

This process is designed merely to furnish a convenient formula for putting opium into the pilular form, preferable to the mode sometimes practised of making the pills directly from the unpowdered mass of opium as found in commerce. The soap answers no other purpose than to give a due consistence, and is therefore in small proportion. Each pill contains a grain of opium.

As hard old opium pills are sometimes preferred, in cases of irritable stomach, in consequence of their slow solution, it is proper for the apothecary to keep some in this state to meet the prescription of the physician.

Of either of the officinal pills above directed, one is a medium dose in reference to the full effects of opium. W.

PILULA PLUMBI CUM OPIO. *Br. Pill of Lead and Opium.*

"Take of Acetate of Lead, in fine powder, *thirty-six grains;* Opium, in fine powder, *six grains;* Confection of Roses *six grains.* Beat them into a uniform mass." *Br.*

This pill would be better left to extemporaneous prescription; the requisite proportion of opium to the acetate varying in different cases. The tannic acid of the confection of roses decomposes a portion of the acetate; but the resulting tannate of lead is not inert. The mass contains six parts of the acetate of lead in eight, and may be given in the dose of two or three grains to begin with. W.

PILULÆ QUINIÆ SULPHATIS. *U. S. Pills of Sulphate of Quinia.*

"Take of Sulphate of Quinia *a troyounce;* Gum Arabic, in fine powder, *one hundred and twenty grains;* Clarified Honey *a sufficient quantity.* Mix the Sulphate of Quinia and Gum Arabic; then beat them with Clarified Honey so as to form a mass, to be divided into four hundred and eighty pills." *U. S.*

As the pills made as here directed are apt to become hard, and of difficult solubility when long kept, various other excipients have been recommended to obviate this disadvantage, as honey alone, and confection of roses. Mr. Edward Parrish has long been in the habit of preparing pills of sulphate of quinia, by taking 20 grains of the salt, adding 15 drops of aromatic sulphuric acid, and triturating until the mixture assumes a pilular consistence. Though at first liquid, the mixture soon thickens, and finally becomes quite solid. The officinal sulphate is thus rendered more soluble by combining with an additional eq. of sulphuric acid. The advantages of this process are the solubility of the resulting pill, and the smallness of its bulk. A five-grain pill made in this way is not inconveniently large. (*Am. Journ. of Pharm.*, xxv. 292.)

Each of the officinal pills contains a grain of the sulphate of quinia, and twelve are equivalent to an ounce of good Peruvian Bark. W.

* The blue pill is sometimes wanted in the state of powder; but, from its peculiar constitution, is not eligible for reduction to this form; as the mercury is disposed to aggregate during pulverization, and, from the honey it contains, it is apt, when pulverized, to attract moisture from the air. Mr. Ch. Bullock, therefore, recommends the following method of preparing a powder, which shall, as nearly as possible, represent the blue pill, in reference to its therapeutic effects. Take of finely powdered Elm-bark, finely powdered Sugar, and Mercury, equal parts, and of Alcohol a sufficiency. Rub the mercury with the powdered bark, adding from time to time enough alcohol to maintain a pasty consistence, till the mercury is completely extinguished; then spread the mass on paper to dry. When dry, powder it, add the sugar, and rub the mixture thoroughly until the powder will pass through a sieve of fine bolting cloth. (*Am. Journ. of Pharm.*, May, 1859, p. 271.)—*Note to the twelfth edition.*

PILULÆ RHEI. *U. S. Pills of Rhubarb.*

"Take of Rhubarb, in fine powder, *three hundred and sixty grains;* Soap, in fine powder, *one hundred and twenty grains.* Beat them together with water so as to form a pilular mass, to be divided into one hundred and twenty pills." *U. S.*

Rhubarb is so often given in the pilular form, that it is convenient both for the physician and apothecary to have an officinal formula, indicating the mode of preparing the pills, as well as the quantity of rhubarb to be contained in each. Soap, as directed by the U. S. Pharmacopœia, has stood the test of long experience as a good excipient for rhubarb. We have found rhubarb pills, made with compound tincture of cardamom, without other ingredient, to answer an excellent purpose. Each officinal pill contains three grains of rhubarb. W.

PILULÆ RHEI COMPOSITÆ. *U. S.* PILULA RHEI COMPOSITA. *Br. Compound Pills of Rhubarb. Compound Rhubarb Pill.*

"Take of Rhubarb, in fine powder, *a troyounce;* Socotrine Aloes, in fine powder, *three hundred and sixty grains;* Myrrh, in fine powder, *half a troyounce;* Oil of Peppermint *half a fluidrachm.* Beat them together with water so as to form a pilular mass, to be divided into two hundred and forty pills." *U. S.*

"Take of Rhubarb, in fine powder, *three ounces;* Socotrine Aloes, in fine powder, *two ounces and a quarter;* Myrrh, in fine powder, *one ounce and a half;* Hard Soap *one ounce and a half;* English Oil of Peppermint *one fluidrachm and a half;* Treacle, by weight, *four ounces.* Reduce the Soap to a fine powder, and triturate it with the Rhubarb, Aloes, and Myrrh, then add the Treacle and Oil of Peppermint, and beat the whole into a uniform mass." *Br.*

This is a warm tonic laxative, useful in costiveness with debility of stomach. From two to four pills, or from ten to twenty grains of the mass, may be taken twice a day. W.

PILULÆ SAPONIS COMPOSITÆ. *U. S.* PILULA OPII. *Br. Compound Pills of Soap.*

"Take of Opium, in fine powder, *sixty grains;* Soap, in fine powder, *half a troyounce.* Beat them together with water so as to form a pilular mass." *U. S.*

"Take of Opium, in fine powder, *half an ounce;* Hard Soap *two ounces;* Distilled Water *a sufficiency.* Reduce the Soap to a fine powder, add the Opium with the Water, and beat into a uniform mass." *Br.*

This preparation is useful by affording the opportunity of conveniently administering opium, in a pilular and readily soluble form, in small fractions of a grain. The name used in the former British Pharmacopœias, and adopted in our own, was probably intended to conceal the nature of the preparation from the patient. Both the name, however, and the object have been abandoned by the British Council. One grain of opium is contained in five of the mass. W.

PILULÆ SCILLÆ COMPOSITÆ. *U. S.* PILULA SCILLÆ COMPOSITA. *Br. Compound Pills of Squill. Compound Squill Pill.*

"Take of Squill, in fine powder, *sixty grains;* Ginger, in fine powder, Ammoniac, in fine powder, each, *one hundred and twenty grains;* Soap, in fine powder, *one hundred and eighty grains;* Syrup *a sufficient quantity.* Mix the powders together; then beat them with Syrup so as to form a pilular mass, to be divided into one hundred and twenty pills." *U. S.*

"Take of Squill, in fine powder, *one ounce and a quarter;* Ginger, in fine powder, Ammoniac, in powder, Hard Soap, each, *one ounce;* Treacle *two ounces*, or *a sufficiency.* Reduce the Soap to powder, and triturate it with the Squill, Ginger, and Ammoniac; then add the Treacle, and beat into a uniform mass." *Br.*

This is a stimulant expectorant compound, depending for its virtues chiefly

on the squill, and applicable to the treatment of chronic affections of the bronchial mucous membrane. From five to ten grains may be given three or four times a day. The preparation should be made when wanted for immediate use, as the squill which it contains is liable to be injured by keeping. W.

PLUMBUM.

Preparations of Lead.

Of the Preparations formerly considered under this head, *Solution of Subacetate of Lead* and *Diluted Solution of Subacetate of Lead* have been transferred to the LIQUORES or *Solutions;* and *Iodide of Lead*, of the U. S. Pharmacopœia, is the only one remaining.

PLUMBI IODIDUM. *U. S. Iodide of Lead.*

"Take of Nitrate of Lead, Iodide of Potassium, each, *four troyounces;* Distilled Water *a sufficient quantity*. With the aid of heat, dissolve the Nitrate of Lead in a pint and a half, and the Iodide of Potassium in half a pint of Distilled Water, and mix the solutions. Allow the precipitate formed to subside, and, having poured off the supernatant liquid, wash it with Distilled Water, and dry it with a gentle heat." *U. S.*

In this process the nitrate of lead gives up its metal to the iodine, from which it receives the potassium; the operation taking place between single equivalents of the several ingredients. The nitrate of potassa thus formed remains in solution, while the iodide of lead is precipitated. The saturating proportions of nitrate of lead and iodide of potassium are 165·6 of the former and 165·5 of the latter, or almost precisely equal quantities. The proportions should be as nearly as possible those of exact saturation. An excess of the iodide of potassium, independently of the waste, has the disadvantage of holding a portion of the iodide of lead in solution; while, according to Christison, an excess of lead over the iodine disposes to the formation of the lemon-yellow insoluble oxyiodide of lead. By the use of equal quantities of the two salts, these disadvantages are avoided. As iodide of lead is slightly soluble in cold water, it is desirable to use as little of the menstruum as will answer; and hence the comparatively small proportion of water employed.

Iodide of lead has been omitted in the present British Pharmacopœia; though all the three Colleges, the London, Edinburgh, and Dublin, gave processes for it. In the London process acetate of lead was employed instead of the nitrate; but M. Depaire, of Brussels, ascertained that, in this process, a considerable amount of iodine remains in solution after the precipitation of the iodide of lead; and M. F. Boudet states that the quantity of the iodide resulting from the process is 10 per cent. less than theory would indicate. By the addition of nitric acid to the solution, after precipitation, an additional quantity of iodide of lead is obtained. M. Boudet ascribes this result to the formation of a portion of soluble iodide of potassium and lead, whenever iodide of lead and acetate of potassa are in contact. By substituting nitrate for acetate of lead, he found that a quantity of iodide of lead was obtained, as near that required by theory as the solubility of the iodide of lead permits. (*Journ. de Pharm.*, 3*e sér.*, xi. 274.)

From the above remarks it would appear that the process of the U. S. Pharmacopœia is on the whole to be preferred, and especially over that in which the acetate of lead is used, as the nitrate is more easily obtained pure. Some interesting experiments have been made by M. T. Huraut, of Paris, on the different methods of preparing iodide of lead. It may be obtained by the reaction between any of the soluble iodides and the soluble salts of lead. It resulted from his observations that of the two salts of lead employed, the nitrate was to be preferred, and of the various iodides, though iodide of potassium yielded a very handsome

product, yet iodide of calcium afforded one not inferior in quality, and somewhat greater in quantity. Upon a small scale, as the process is performed by the apothecary, the difference would be of little or no consequence; but it might be important to the manufacturer. (See *Am. Journ. of Pharm.*, xxi. 228.)

As obtained by the U. S. process, iodide of lead is in the form of a bright-yellow, heavy, tasteless, inodorous powder. It is soluble in 1235 parts of cold water (Soubeiran, *Trait. de Pharm.*), and 194 of boiling water, which, on cooling, deposits it in minute, shining, golden-yellow, crystalline scales. It melts by heat, and is dissipated in vapours, which are at first yellow, and ultimately violet in consequence of the disengagement of the iodine. It consists of one equivalent of iodine 126·3, and one of lead 103·6 = 229·9. As a test of its purity, the Edinburgh College stated that five grains are entirely dissolved, with the aid of heat, by a fluidrachm of pyroligneous acid, diluted with a fluidounce and a half of distilled water; and golden crystals are copiously deposited when the solution cools. According to the late London Pharmacopœia, 100 grains of it, dissolved at a boiling heat in nitric acid diluted with two parts of water, will, after the expulsion of the iodine, yield with sulphate of soda, a precipitate of sulphate of lead weighing 66 grains. It should be kept excluded from the light. It is stated by Engelhardt that iodine is separated from iodide of lead by the perchlorides of iron and copper; while the other metallic chlorides, whether bichlorides, sesquichlorides, or protochlorides, have no such effect, producing compounds of iodides of the metal employed with chlorides of lead. (*Chem. Gaz.*, Jan. 15, 1856, p. 24.)

Medical Properties and Uses. This compound is supposed to have the resolvent properties of iodine, combined with those which are peculiar to lead, and was at one time recommended in tuberculous diseases, in which, however, it has proved wholly inefficient. It is said to have been usefully employed in the discussion of scrofulous tumours and other indolent swellings, and in the cure of obstinate ulcers; and for these purposes has been used both internally, and locally in the form of an ointment. According to Dr. Cogswell, if given for some time in small doses, it produces the effects of lead, but not those of iodine, upon the system. (*Christison's Dispensatory.*) The dose is from half a grain to three or four grains. Dr. O'Shaughnessy states that ten grains are borne without inconvenience. W.

POTASSA.

Preparations of Potassa.

Of the Preparations formerly embraced in this category, the *Solution of Potassa*, and the *Solution of Citrate of Potassa* have been transferred to the LIQUORES or *Solutions; Pure Nitrate of Potassa*, Dub., has been treated of in *Part I.* of this work; and the following preparations, at one time officinal, have been omitted in the existing Pharmacopœias; namely, *Solution of Carbonate of Potassa*, U. S., Lond., Dub., *Effervescing Water of Potassa*, Ed., *Sulphate of Potassa with Sulphur*, Ed., *Bisulphate of Potassa*, Ed., Dub., and *Compound Solution of Iodide of Potassium*, Lond., Dub.

POTASSA. *U. S.* POTASSA CAUSTICA. *Br. Potassa. Caustic Potassa. Hydrate of Potassa.*

"Take of Solution of Potassa *eight pints.* Evaporate it rapidly in an iron vessel, over the fire, until ebullition ceases, and the Potassa melts. Pour this into suitable moulds, and keep it, when cold, in a well-stopped bottle." *U. S.*

"Take of Solution of Potash *two pints* [Imperial measure]. Boil down the Solution rapidly in a silver or clean iron vessel, till all ebullition ceases, and a fluid of oily consistence remains. Pour this into proper moulds, and when it has solidified, and while it is still warm, put it into stoppered bottles." *Br.*

The concrete alkali, obtained by these processes, is the hydrate of potassa,

sufficiently pure for medicinal purposes. The solution of the alkali freed from carbonic acid having been obtained by another formula (see *Liquor Potassæ*), the formation of the present preparation requires merely the evaporation of this solution, until the whole of its uncombined water is driven off. The evaporation must be performed in metallic vessels, as those of glass or earthenware are acted on by the alkali; and it should be completed as quickly as possible, in order to abridge the period during which the solution would be liable to absorb carbonic acid from the atmosphere. When poured out on a metallic plate or dish, the cake, just as it concretes, may be marked with a knife in the directions in which it is to be divided, and when cold it readily breaks in those directions. A better plan, however, is to run the fused alkali into suitable moulds, as directed in the U. S. and British formulas. These should be made of iron and have a cylindrical shape, which is the most convenient form of the alkali for surgical use. Green glass bottles with ground stoppers are best adapted for preserving this preparation, as white flint glass is slightly acted on.

Properties, &c. In its officinal form, potassa is in sticks having a fibrous fracture, and, when properly prepared from pure materials, white and somewhat translucent; but, as often found in the shops, they have a dingy gray or greenish colour, with occasionally a bluish tint, and the peculiar odour of slaking lime. It is extremely caustic and very deliquescent, and dissolves in less than its weight of water, leaving but a slight residue. Its aqueous solution agrees in properties with Liquor Potassæ. It is also readily soluble in alcohol. When exposed to a low red heat it melts, and at bright redness is volatilized. On account of its deliquescent property, and its strong attraction for carbonic acid, it requires to be kept in very accurately stopped bottles. In the state here described, the alkali is united with water, forming hydrate of potassa. As formerly obtained by the U. S., London, and Edinburgh formulas, from solution of potassa derived from an impure carbonate, it contained various impurities, which, however, did not interfere with its medicinal value; such as chloride and teroxide of potassium, sesquioxide of iron, lime, silica, alumina, sulphate of potassa, and a portion of the alkali still in a carbonated state. As our officinal solution of potassa, from which the alkali is now prepared, is made from the bicarbonate, the resulting potassa is purer than as formerly obtained. According to the U. S. Pharmacopœia, it is dissolved by water and alcohol, with the exception of a slight residue, which probably consists chiefly of undecomposed carbonate, as this is insoluble in alcohol. Officinal potassa may be rendered nearly pure by digestion in alcohol, which takes up only the hydrated alkali, evaporating the solution to dryness, and fusing the dry mass obtained. *Hydrate of potassa*, when thus procured, is called *alcoholic potassa*. It is generally in flat white pieces, which are dry, hard, brittle, and extremely caustic. Its other properties are similar to those of the impure hydrate above described. According to Mr. H. Wurtz, of New York, alcoholic potassa usually contains a trace of silicate of potassa, which appears to be taken up by the alcohol. The source of this is the carbonate of potassa employed, which may be freed from this impurity by evaporating its aqueous solution, in a sheet-iron dish, to dryness, and adding, from time to time, lumps of carbonate of ammonia. The silicate is thus converted into the carbonate; and, on dissolving the residue, the silica appears in flakes, which may be separated by filtration. (*N. Y. Journ. of Pharm.*, Feb. 1852.) Potassa may be discriminated from the other fixed alkalies (soda and lithia) by affording, when in solution, a crystalline precipitate (cream of tartar) with an excess of tartaric acid, and a yellow one with bichloride of platinum. Potassa imparts to the flame of burning alcohol in which it is dissolved a reddish tint; soda colours it yellow even in the presence of potassa; and thus a method is afforded of detecting an admixture of the latter with the former alkali. According to Bunsen, when the flame is regarded through a glass of a cobalt blue colour, only the colour imparted by potassa is seen, that

peculiar to soda not being able to penetrate through blue glass. (*Journ. de Pharm.*, Oct. 1860, p. 319.) The officinal potassa, apart from impurities, consists of one eq. of dry potassa 47·2, and one of water 9 = 56·2. Dry potassa is composed of one eq. of potassium 39·2, and one of oxygen 8 = 47·2. (See *Potassium.*) B.

Medical Properties and Uses. This is the old *causticum commune acerrimum* or *strongest common caustic.* It is a powerful escharotic, quickly destroying the life of the part with which it comes in contact, and extending its action to a considerable depth beneath the surface. In this latter respect, it differs from nitrate of silver or lunar caustic, to which it is, therefore, preferred in forming issues and opening abscesses. It has been used for removing stricture of the urethra; but, in consequence of its tendency to spread, it may, unless carefully applied, produce such a destruction of the lining membrane, as to open a passage for the urine into the cellular tissue. The most convenient mode of employing the caustic for the formation of an issue, is to apply to the skin a piece of linen spread with adhesive plaster, having a circular opening in its centre corresponding with the intended size of the issue, and then to rub upon the skin, within the opening, a piece of the caustic previously moistened at one end. The application is to be continued till the life of the part is destroyed, when the caustic should be carefully washed off with a wet sponge or wet tow, or neutralized by vinegar. The preparation is also employed for forming solutions of potassa of definite strength, whether for medicinal or pharmaceutic use. A solution of one drachm and a half of caustic potassa in two fluidounces of distilled water was highly recommended by the late Dr. Hartshorne, of Philadelphia, as an application to the spine in tetanus. It may be applied by means of a sponge attached to the end of a stick, which should be drawn quickly along the back from the nape of the neck to the sacrum. It produces a powerful rubefacient effect.*

POTASSA CUM CALCE. *U. S.* *Potassa with Lime.*

"Take of Potassa, Lime, each, *a troyounce.* Rub them together so as to form a powder, and keep it in a well-stopped bottle." *U. S.*

This preparation is a grayish-white powder, sometimes called *Vienna caustic.* It should not effervesce on the addition of an acid. It is prepared for use by being made up into a paste with a little alcohol. The paste is applied to the part to be cauterized for ten or fifteen minutes, and is conveniently limited in its operation by a piece of adhesive plaster, in the manner explained under potassa. The former Edinburgh preparation, made by evaporating the solution of potassa to one-third, and adding lime enough to bring it to the state of a firm paste, was often called *causticum commune mitius* or *milder common caustic.* Potassa with lime is a more manageable caustic than the officinal potassa, on account of the presence of the lime, which renders it milder, slower in its operation, and less deliquescent, and causes it to spread less beyond the part intended to be affected. Dr. Filhos has improved this caustic by forming it in sticks. To prepare it thus, the potassa is perfectly fused in an iron spoon, and one-third of its

* At the suggestion of Dr. Maunoury, of Chartres, M. E. Robiquet has prepared a paste consisting of gutta percha and caustic potassa, which offers many advantages of manipulation, in the application of the latter substance. It is prepared by simply melting together equal weights of the two substances. The resulting paste can be moulded into any form that may be thought desirable, either of cylinders, plates, or lozenges, and retains its form indefinitely, even when introduced into cavities. All that is necessary, before applying it, is to dip it into alcohol for a few seconds. The resulting eschars are very precise in their form. (*Journ. de Pharm.*, xxx. 275.)—*Note to the eleventh edition.*

weight of quicklime is added in divided portions; the whole being stirred with an iron rod. The fused mass is then run into lead tubes, closed at one end, about three inches long, and from a quarter to half an inch in diameter in the clear. The sticks are kept, still enclosed in the lead tubes with the open end downwards, in thick glass tubes, containing some powdered quicklime, and closed with a cork, between which and the stick some cotton is put to steady the caustic. When employed, as much of the caustic is uncovered at the end, by scraping off the lead, as it is proposed to use. This form of caustic is particularly recommended for cauterizing the neck of the uterus. M. E. Robiquet has modified the caustic, by fusing the potassa and lime at a higher heat, running the fused mass into iron moulds, and quickly coating the sticks, when cold, with melted gutta percha. The higher heat employed renders the caustic harder and more homogeneous.* B.

POTASSÆ ACETAS. *U. S.*, *Br.* *Acetate of Potassa.*

"Take of Acetic Acid *a pint;* Bicarbonate of Potassa *a sufficient quantity.* Add the Bicarbonate gradually to the Acid until this is saturated; then filter the solution, and evaporate cautiously, by means of a sand-bath, until a dry salt remains. Lastly, keep this in a well-stopped bottle." *U. S.*

"Take of Carbonate of Potash *twenty ounces* [avoirdupois]; Acetic Acid [sp. gr. 1·044] *two pints* [Imperial measure], or *a sufficiency.* To the Acetic Acid, placed in a thin porcelain basin, add gradually the Carbonate of Potash, filter, acidulate, if necessary, with a few additional drops of the Acid, and, having evaporated to dryness, raise the heat cautiously so as to liquefy the product. Allow the basin to cool, and, when the salt has solidified, and while it is still warm, break it in fragments, and put it into stoppered bottles." *Br.*

The process for forming this acetate is a case of single elective affinity. The substitution in the present Pharmacopœia, of the bicarbonate of potassa for the carbonate used in the formula of 1850, is an improvement, as it ensures a purer product. The form of acid for generating the salt directed in both Pharmacopœias is officinal acetic acid. Distilled vinegar should never be employed, on account of organic impurity, which gives the solution, when concentrated, a reddish or brownish colour. When acetic acid is used, a colourless solution is obtained. This is evaporated to dryness, according to the U. S. and British Pharmacopœias; but the latter, following the late Dublin Pharmacopœia, directs the dry salt to be melted, so that it may be obtained as a solid mass on cooling. When fusion is resorted to, great care must be taken not to use too high a heat; as otherwise part of the acetic acid will be decomposed, and the resulting salt will be discoloured. For drying the acetate of potassa, Dr. Christison considers the heat of a vapour-bath too low, and that of a sand-bath apt to become too high. He, therefore, recommends the use of a bath of chloride of calcium when operating on a small scale. In conducting the evaporation, it is best to have the solution always slightly acid; for if the alkali predominate, it will react upon the acetic acid when the solution is concentrated, and give rise to discoloration.

Acetate of potassa may also be obtained by double decomposition between acetate of lead and sulphate of potassa. When thus procured it is very white and pure, but liable to the objection, for medical use, that it may possibly contain a little lead. Another method by double decomposition is between acetate of lime and sulphate of potassa.

Properties, &c. Acetate of potassa when pure is a white salt, perfectly neutral

* M. Piedagnel has found that by mixing the Vienna powder with muriate of morphia, in the proportion of three parts of the former to one of the latter, a caustic is obtained, which will produce an eschar without causing pain. He first mixes them intimately in the dry state, and then with alcohol, chloroform, or water, makes a paste, which may be applied by means of adhesive plaster. (*Journ. de Pharm.*, 3e *sér.*, xxxiii. 469.)—*Note to the twelfth edition.*

to test paper, unctuous to the touch, and of a warm, pungent, saline taste. When unskilfully prepared it is apt to be more or less coloured. Its state of aggregation differs with the manner in which it is prepared. As obtained by evaporating the solution to dryness, agreeably to the directions of the U. S. Pharmacopœia, it is in the form of soft fibrous masses. As usually prepared and found in the shops, it has a foliated texture, which is given to it by fusion and cooling. On account of this appearance it was formerly called *foliated earth of tartar*. This salt is extremely deliquescent, and, if exposed to the air, becomes converted into a liquid of an oleaginous appearance. It is on account of this property that it must always be preserved in well-stopped bottles. It dissolves in about half its weight of water, and twice its weight of alcohol. Anything remaining undissolved by these menstrua is impurity. Heated above its point of fusion, it is decomposed into acetone and carbonate of potassa; the acetic acid being resolved into that volatile liquid and carbonic acid. When treated with sulphuric acid, acetous vapours are copiously evolved, and sulphate of potassa is formed; and a blood-red colour is produced by a solution of sesquichloride of iron. One hundred grains of the salt, decomposed by sulphuric acid, furnish a salt (sulphate of potassa), which, after exposure to a strong heat, weighs 88·8 grains. (*Lond. Pharm.*) The most usual impurities contained in it are sulphate and tartrate of potassa, chloride of potassium, and the salts of lead and copper. A soluble sulphate may be detected by chloride of barium; and chloride of potassium, or other soluble chloride, by nitrate of silver added to a *dilute* solution. If the nitrate be added to a concentrated solution, crystals of acetate of silver will be precipitated, soluble in water or dilute nitric acid. With bichloride of platinum it yields a yellow, and with tartaric acid a crystalline precipitate, showing it to be a salt of potassa. If tartate of potassa be present, it will remain undissolved when the salt is acted on by alcohol. Lead and copper may be detected by sulphuretted hydrogen and ferrocyanide of potassium; the former test producing with the lead a blackish, and the latter with the copper a brown precipitate. Since the introduction of the cheap method of obtaining pure acetic acid from wood, this salt has scarcely been subjected to adulteration. Acetate of potassa is incompatible with the mineral acids, which expel the acetic acid; with the sulphates of soda and magnesia; with corrosive sublimate and nitrate of silver; and with several other earthy and metallic salts. This salt exists in the juices of many plants, and especially in the sap of trees, and is the principal source of the carbonate of potassa existing in the ashes of wood. It consists of one eq. of acetic acid 51, one of potassa 47·2, and two of water 18 = 116·2.

Medical Properties and Uses. Acetate of potassa acts as a diuretic in doses of from a scruple to a drachm, and as a mild cathartic when given to the extent of two or three drachms. It is employed in dropsies, and often with good effect. The late Dr. Duncan, of Edinburgh, considered it to be a medicine of great efficacy, and one of our best saline deobstruents. Dr. J. A. Easton, of Glasgow, has found it useful in several skin diseases, such as psoriasis, eczema, and lepra. Cases which had resisted the ordinary remedies were cured, after a treatment occupying from three weeks to two months. The dose given by Dr. Easton was half a drachm, three times a day, dissolved in water. The remedy seemed to act through the kidneys, the urine being remarkably increased, both in its aqueous and solid contents. The late Dr. Golding Bird treated a large number of cases of acute rheumatism with remarkable success with this salt. The pain of the disease declined as soon as the urine became alkaline and rose in specific gravity. The quantity given, in twenty-four hours, was half an ounce in divided doses, largely diluted with water. (*Braithwaite's Retrospect*, Am. ed., July, 1854, p. 43.) It has been highly recommended by Ambrosoli in large doses as a remedy in acute and subacute urethritis with mucous or puruloid discharge, and in similar affections of the vagina and uterus. (*Ann. de Thérap.*, 1863, p. 115.) Ace-

tate of potassa may be made extemporaneously in the liquid form by saturating distilled vinegar with carbonate of potassa. Two drachms of the carbonate, saturated with vinegar, will sometimes produce in hydropic cases ten or twelve stools, and a copious discharge of urine. (*Duncan.*) Acetate of potassa, like the other alkaline salts containing a vegetable acid, may be given in the uric acid diathesis, to render the urine alkaline; for the experiments of Wöhler have shown that the acid of these salts undergoes decomposition in the digestive and assimilating processes, while the alkali enters the current of the circulation. From the decided property which this salt possesses of increasing the secretion of the kidneys, it was formerly called *sal diureticus* or *diuretic salt.* B.

POTASSÆ CARBONAS. *U. S., Br. Carbonate of Potassa. Carbonate of Potassa from Pearlash.*

"Take of Impure Carbonate of Potassa [pearlash] *thirty-six troyounces;* Water *two pints and a half.* Dissolve the Impure Carbonate in the Water, and filter the solution; then pour it into an iron vessel, and evaporate over a gentle fire until it thickens. Lastly, remove it from the fire, and stir constantly with an iron spatula until it forms a granular salt." *U. S.*

In the British Pharmacopœia this salt is placed in the catalogue of the Materia Medica, without any process for its preparation, or intimation of its source, but with the following account of its characters, from which we may infer that it may possibly be obtained, like the U. S. carbonate, from pearlash. "When supersaturated with nitric acid, and evaporated to dryness, the residue is almost entirely soluble in water, only a little remaining undissolved. It is precipitated only faintly by chloride of barium and nitrate of silver. Eighty-seven grains require for neutralization at least ninety-eight measures of the *volumetric solution of oxalic acid.*"

The object of the above process is to purify the impure carbonate of potassa, or pearlash. This generally contains certain insoluble impurities, as well as small portions of sulphate and silicate of potassa, and chloride of potassium, as explained under another head. (See *Potassæ Carbonas Impurus.*) By dissolving it in a due proportion of water, and filtering the solution, the insoluble impurities are got rid of, as well as the greater part of the foreign salts, which, being much less soluble than the carbonate of potassa, are excluded by the superior affinity of this salt for the water. The proper way of conducting the purification is to mix the impure carbonate with an equal weight of *cold water*, and to allow the mixture to stand for a day or two, stirring it frequently to promote the action of the water. The clear liquor obtained by decantation or filtration is then evaporated to dryness. The officinal process is conducted very much in this way; cold water being employed, and about equal weights of alkali and water being used. The prolonged contact of the water with the salt, and the occasional stirring of the mixture, formerly ordered by the Dublin College, were useful directions. In no case should the undissolved residue be washed with a fresh portion of water; as, by such a proceeding, the foreign salts, which it is the object of the process to separate, would be dissolved. Iron vessels are directed, because this metal is not acted on by the alkali, while glass is attacked by it. In granulating the salt by stirring, it is better, when the solution is brought nearly to dryness, to keep it on the fire at a reduced heat until the process is finished, than to remove it the moment it thickens.

According to Berzelius, a more productive process for purifying pearlash, though the resulting salt is not so pure as when obtained in the way just described, is to dissolve the pearlash in more than its weight of water, to evaporate the solution till it has the sp. gr. 1·52, and then to put it in a cool place, that the foreign salts, principally sulphate of potassa and chloride of potassium, may crystallize. The solution is then decanted, and evaporated to dryness.

To get rid of the silica, Rieckher proposes to evaporate the solution, exempt

from sulphate, to dryness, to moisten the residue with solution of carbonate of ammonia, and again evaporate. The silica separates, and passes into the insoluble state at the temperature necessary for evaporation. By again dissolving and evaporating, the carbonate is obtained free from this impurity. (*Chem. Central Blatt*, 1863. p. 158.)

Properties, &c. Carbonate of potassa, as found in the shops, is in the form of a coarse, granular, white powder, having a nauseous, alkaline taste, and acting as an alkali on vegetable colours. It is very soluble in water, dissolving in its weight of that liquid, but is insoluble in alcohol. It is extremely deliquescent; and hence a portion of it, exposed to the air for some time, attracts so much water as completely to dissolve into an oily liquid, called by the older chemists, *oleum tartari per deliquium*. On account of this property, carbonate of potassa should be kept in bottles with accurately ground stoppers. If exposed in its usual state to a red heat, it retains its carbonic acid, but loses 16 per cent. of water; and, when decomposed by dilute sulphuric acid, evolves 26·3 per cent. of carbonic acid. (*Lond. Pharm.*) It should be completely soluble in water; but, generally, a small insoluble portion is left of earthy matter. The usual impurities are earthy matter, sulphate of potassa, chloride of potassium, and silica in the state of silicate of potassa. When dissolved in water and treated with nitric acid in excess, it affords a faint cloudiness with chloride of barium, and a slight precipitate with nitrate of silver; effects showing the presence of minute portions of a sulphate and of a chloride. The nitric solution is also precipitated by carbonate of soda, if earthy matter be present. If the indications of these tests are decided, the salt is below the officinal standard of purity. Its aqueous solution, saturated by an acid, slowly deposits a slight flocculent precipitate of hydrated silica. It is incompatible with acids and acidulous salts, muriate and acetate of ammonia, lime-water, chloride of calcium, sulphate of magnesia, alum, tartar emetic, nitrate of silver, ammoniated copper and ammoniated iron, sulphate of iron, tincture of chloride of iron, calomel and corrosive sublimate, acetate and subacetate of lead, and sulphate of zinc. It is not decomposed by tartrate of iron and potassa.

Composition. Carbonate of potassa, after exposure to a red heat, is anhydrous, consisting of one eq. of carbonic acid 22, and one of potassa 47·2 = 69·2. Obtained by the officinal formulas, it is, according to Mr. Phillips, a sesquihydrate, containing two eqs. of carbonate and three of water. According to the Br. Pharmacopœia, each eq. of the salt denominated by it carbonate of potassa contains two eqs. of water; its formula being KO,CO_2+2HO; but this is not precisely the salt under consideration; nor does the Pharmacopœia indicate its source. When exposed to the air, carbonate of potassa absorbs sufficient water, before losing its solid form, to give it three equivalents; with more it begins to deliquesce. (Dr. Pohl. See *Am. Journ. of Pharm.*, Nov. 1861, p. 532.) B.

Medical Properties and Uses. Purified pearlash is the form of carbonate of potassa usually employed in this country, where it is frequently, though incorrectly, called *salt of tartar;* the latter name being strictly applicable to the purer carbonate obtained by decomposing cream of tartar. It is occasionally used as an antacid in dyspepsia, a diuretic in dropsy, and antilithic in gravel attended with red deposits in the urine; but the purpose to which it is most commonly applied is the formation of the *neutral mixture* and *effervescing draught.* (See *Liquor Potassæ Citratis.*) It is also used with advantage in some cases of jaundice, in which it probably operates by entering the circulation, and directly exciting the hepatic function. It has enjoyed considerable popular reputation mixed with cochineal in hooping-cough, and is supposed by some, in common with other alkaline remedies, to operate favourably in pseudo-membranous inflammations of the mucous tissues. It is considered among the most effectual remedies in obstinate cutaneous eruptions, in which it is employed both inter-

nally and externally. The dose is from ten to thirty grains, given in some aromatic water sweetened with sugar. In large quantities it acts as a corrosive poison, and is capable of producing death in a few hours. The antidotes are the fixed oils and vegetable acids.

As a local remedy in cutaneous affections, carbonate of potassa is used in the form of bath, of lotion, and of ointment. From eight to sixteen ounces may be used for a single bath, the quantity being gradually increased. Lotions may be made by dissolving two or three drachms in a pint of water; and ointments, by rubbing from ten grains to a drachm with an ounce of lard.

A solution of the salt, on exposure to the air, or on the addition of an acid, deposits flocculi consisting of hydrate of silica, resulting from the decomposition of silicated potassa, which is always present as an impurity. The spontaneous deposition of silica is owing to the absorption of carbonic acid.

POTASSÆ CARBONAS PURA. *U. S. Pure Carbonate of Potassa. Salt of Tartar.*

"Take of Bicarbonate of Potassa, in coarse powder, *twelve troyounces.* Put it into a capacious iron crucible, heat gradually until the water of crystallization is driven off; then raise the heat to redness, and maintain that temperature for half an hour. Having taken the crucible from the fire, and allowed it to cool, dissolve its contents in Distilled Water, and filter the solution. Then pour it into an iron vessel, and evaporate over a gentle fire until it thickens. Lastly, remove it from the fire, and stir constantly with an iron spatula, until it forms a granular salt." *U. S.*

In this process the bicarbonate of potassa is ignited, whereby it loses its water of crystallization and second equivalent of carbonic acid, and is reduced to the state of carbonate. As the bicarbonate is a very pure salt, so the carbonate obtained from it is also very pure.

The pure carbonate was formerly obtained from bitartrate of potassa, by first purifying it by solution and crystallization, and then incinerating it; and this was one of the processes of the late Edinburgh Pharmacopœia. The tartaric acid, which consists of carbon, hydrogen, and oxygen, is decomposed, and gives rise, among other products, to carbonic acid, which combines with the potassa. The matter, after ignition, contains, besides carbonate of potassa, certain impurities derived from the bitartrate. These are carbonate of lime arising from the decomposition of tartrate of lime, alumina, and minute portions of the oxides of iron and manganese; but, being all insoluble in water, they are left behind when the mass is acted on by that liquid, the alkaline carbonate being taken up. Some silicate of potassa is sometimes dissolved, derived from silica, either originally in the bitartrate, or derived from the earthenware or porcelain crucible in which the ignition is performed.

Pure carbonate of potassa may also be obtained by deflagrating a mixture of two parts of bitartrate of potassa, and one of nitrate of potassa. This process has been objected to on the ground that it gives a carbonate, apt to contain a little of the poisonous cyanide of potassium. But this objection is unfounded. It is true, as Engelhardt and Wicke have proved, that the deflagrated mass contains cyanate of potassa; but this is entirely decomposed into ammonia and carbonate of potassa by the subsequent operations of solution and evaporation to dryness, to which the mass is subjected.

It was this origin from bitartrate of potassa, called in its impure state *tartar*, that gave rise to the name of *salt of tartar*, still frequently applied to the purer forms of the carbonate. It may, indeed, be very much doubted whether the real salt of tartar is often kept in our shops; the ordinary carbonate, as purified from pearlash, being generally substituted for it, and answering, in most cases, every medicinal purpose that could be expected from the use of the purer salt.

Properties, &c. Pure carbonate of potassa, obtained from the bicarbonate of cream of tartar, differs from the same salt procured from pearlash, in containing no impurities. With the tests mentioned under the carbonate it gives negative indications, showing the entire absence of foreign substances. The U. S. Pharmacopœia gives the following characters of the salt. It is white, deliquescent, and wholly soluble in water; effervesces with acids, and has an alkaline reaction; yields, in solution, a yellow precipitate with bichloride of platinum, and a white one effervescing with acids, with sulphate of magnesia; when saturated with an acid deposits nothing upon standing, and, when treated with pure nitric acid in excess, is not precipitated by carbonate of soda, chloride of barium, or nitrate of silver. It loses 16 per cent. of its weight at a red heat.

Medical Properties and Uses. These are the same with those of the carbonate of potassa described in the preceding article. The pure carbonate, on account of its freedom from silica, furnishes the best material for forming the solution of citrate of potassa, or neutral mixture.

POTASSÆ BICARBONAS. *U. S.*, *Br.* *Bicarbonate of Potassa.*

"Take of Carbonate of Potassa *forty-eight troyounces;* Distilled Water *ten pints.* Dissolve the Carbonate in the Distilled Water, and pass carbonic acid through the solution till it is fully saturated. Then filter the liquid, and evaporate that crystals may form, taking care that the heat does not exceed 160°. Lastly, pour off the supernatant liquid, and dry the crystals upon bibulous paper. Carbonic Acid may be obtained from marble by the addition of dilute sulphuric acid." *U. S.*

"Take of Carbonate of Potash *one pound* [avoirdupois]; Distilled Water *two pints* [Imperial measure]; Hydrochloric Acid of Commerce *one pint and a half* [Imp. meas.]; Water *three pints* [Imp. meas.]; White Marble, in fragments, *one pound* [avoird.], or *a sufficiency.* Dissolve the Carbonate of Potash in the Distilled Water, and filter the solution into a three-pint bottle, capable of being tightly closed by a cork, traversed by a glass tube sufficiently long to pass to the bottom of the fluid. Introduce the Marble into another bottle, in the bottom of which a few small holes have been drilled, and the mouth of which is closed by a cork, also traversed by a glass tube, and place the bottle in a jar, of the same height as itself, but of rather larger diameter. Connect the two glass tubes, air-tight, by a caoutchouc tube. The cork of the bottle containing the Carbonate of Potash having been placed loosely, and that of the bottle containing the marble tightly, in its mouth, pour into the jar surrounding the latter bottle the Hydrochloric Acid, previously diluted with the Water. When the carbonic acid gas has passed through the potash solution for two minutes so as to expel the whole of the air of the apparatus, fix the cork tightly in the neck of the bottle, and let the process go on for a week. At the end of this time numerous crystals of Bicarbonate of Potash will have formed, which are to be removed, shaken in a capsule with twice their bulk of cold Distilled Water, and, after decantation of the water, drained, and dried on filtering paper by exposure to the air. The mother-liquor, filtered, if necessary, and concentrated to one-half, at a temperature not exceeding 110°, will yield more crystals. The tube immersed in the solution of carbonate of potash, which should have as large a diameter as possible, may require the occasional removal of the crystals formed within it, in order that the process may not be interrupted." *Br*

In these processes, the carbonate of potassa, consisting of one eq. of acid and one of base, is combined with an additional equivalent of carbonic acid. The combination is effected by passing a stream of this acid through a solution of the carbonate, so long as it is absorbed. In the U. S. formula the distilled water taken is about three times the weight of the carbonate. As the bicarbonate of potassa requires four times its weight of water to dissolve it, the quantity of water ordered in the U. S. formula would seem not to be sufficient to dissolve the new salt; unless it be assumed that the solution becomes heated in consequence of the reaction. The solution of the whole of the new salt is not intended in the British process, which proceeds on the plan of forming crystals of bicarbonate at once in the original solution, without concentration by heat. The filtration directed in the U. S. formula is ordered on the presumption that the whole of the bicarbonate formed is dissolved; and is intended to separate silica, which is always deposited during the progress of the saturation, when carbonate of potassa from pearlash is employed. On a small scale the saturation of the carbonate is best conducted in a Wolfe's apparatus of three bottles; the first containing water to wash the carbonic acid gas, the two others, solutions of the carbonate. The bottles should be connected by means of wide tubes, to prevent their being obstructed by the crystals formed. On a large scale the saturation is performed in strong vessels, into which the carbonic acid is driven under pressure. Sulphuric acid is always used by the manufacturing chemist for generating the carbonic acid; but in small operations, muriatic acid, diluted with twice its bulk of water, is more convenient; inasmuch as it generates with the marble or chalk a soluble salt (chloride of calcium), which does not interfere with the extrication of the carbonic acid, as the insoluble sulphate of lime does. In the British process dilute muriatic acid is used for the extrication of the carbonic acid, which is effected in a self-regulating generator of that gas.

In the process of the late Ed. Pharmacopœia, carbonate of ammonia was incorporated with carbonate of potassa, by the assistance of a little water, so as to form a uniform pulp, which was dried by a gentle heat. By the combined influence of the volatility of the ammonia, and the affinity of the carbonate of potassa for carbonic acid, the carbonate of ammonia was totally decomposed; its carbonic acid generating the bicarbonate by uniting with the carbonate, and its ammonia being evolved during the drying of the pulp, which was then reduced to a fine powder. This process is alleged by Dr. Christison to be superior to the other "in point of economy, dispatch, and certainty in small operations."

Mr. Brande gives the following proportions for the preparation of bicarbonate of potassa on the large scale: "100 lbs. of purified carbonate of potassa are dissolved in 17 gallons of water, which, when saturated with carbonic acid, yield from 35 to 40 lbs. of crystallized bicarbonate; 50 lbs. of carbonate of potassa are then added to the mother-liquor, with a sufficient quantity of water to make up 17 gallons, and the operation repeated."

Wöhler states that charcoal, when mixed with the carbonate, facilitates by its porosity, in a remarkable degree, the formation of the bicarbonate. Thus he found that, when crude tartar was charred in a covered crucible, and the carbonaceous mass, after having been slightly moistened with water, was subjected to a stream of carbonic acid, the gas was absorbed with great rapidity, and heated the mass so considerably, as to render it necessary to surround the vessel with cold water, to prevent the decomposition of the bicarbonate formed. When the temperature diminished, the saturation was known to be completed. The mass was lixiviated in the smallest quantity of water at the temperature of from 85° to 100°, and the solution, after filtration and cooling, deposited the greater part of the bicarbonate in fine crystals. (See *Am. Journ. of Pharm.*, x. 82.)

M. Behrens has proposed to obtain bicarbonate of potassa by partially saturating the carbonate, dissolved in an equal weight of water, with acetic acid

gradually added. Up to a certain point, no carbonic acid is extricated, and a precipitate takes place of pure bicarbonate of potassa, equal to half the weigh. of the carbonate employed. After the bicarbonate is separated, the saturation may be completed, and acetate of potassa obtained. (*Journ. de Pharm.*, 3*e sér.*, iv. 464.) The bisalt is also produced when the carbonate is treated with weak lemon-juice in forming the citrate. (See *page* 1217.)

According to Berzelius, the cheapest method of obtaining the bicarbonate of potassa is to suspend a concentrated solution of the purified carbonate, contained in a stoneware dish, within a cask, over a liquid undergoing the vinous fermentation. The alkali is thus surrounded by an atmosphere of carbonic acid, and, by absorbing it, crystallizes into bicarbonate in the course of five or six weeks. Distillers and brewers may prepare this salt with great facility by suspending the alkaline solution in the fermenting tun. The salt in powder called *sal aëratus*, made principally in New England, is, we believe, prepared in this way. In composition it is between a carbonate and bicarbonate.

Properties, &c. Bicarbonate of potassa is in transparent, colourless crystals, slightly alkaline to the taste and to test paper, permanent in the air, and having the shape of irregular eight-sided prisms with two-sided summits. It dissolves in four times its weight of cold water, and in five-sixths of its weight of boiling water, by which it is partially decomposed, and converted into *sesquicarbonate*. It is insoluble in alcohol. Exposed to a red heat, it loses 30·7 per cent., comprising half its carbonic acid and the whole of its water of crystallization, and returns to the state of carbonate, which, when thus obtained, is free from silica, and otherwise very pure. This method is now adopted in the U. S. Pharmacopœia for obtaining the pure carbonate. Treated with nitric acid in excess, it should give a clear solution, the transparency of which is not disturbed by chloride of barium, and but slightly by nitrate of silver. When a perfect bicarbonate, its solution, unless heated, does not precipitate a solution of sulphate of magnesia. This negative indication, however, cannot be depended upon as showing the absence of carbonate; for, according to Dr. Christison, no precipitate will be occasioned, even when 50 per cent. of this impurity is present. Bicarbonate of potassa does not decompose calomel. When dissolved in 40 parts of water, it produces a white haze merely with a solution of corrosive sublimate; but if it contain so much as a hundredth part of carbonate, a brick-red precipitate is immediately produced. (*Christison.*) Another way of detecting the presence of carbonate is to add starch sugar to a heated solution of the suspected bicarbonate. If any carbonate be present, the mixture turns yellow or brown. (*Chevallier.*) Bicarbonate of potassa consists of two eqs. of carbonic acid 44, one of potassa 47·2, and one of water 9 = 100·2. "Fifty grains exposed to a low red heat, leave 34·5 grains of a white residue, which requires for exact saturation fifty measures of the *volumetric solution of oxalic acid.*" *Br.*

Medical Properties. The medical properties of this salt are similar to those of the carbonate, to which it is preferable from its milder taste, and greater acceptability to the stomach. The dose is from twenty grains to a drachm. Dr. Garrod, of London, has had great success in the treatment of acute rheumatism by the use of two-scruple doses of this salt, given in weak solution, every two hours, day and night, and continued for a few days after the articular affection and febrile disturbance have subsided. The salt probably acts by rendering the secretions alkaline, and by increasing the alkalinity of the blood. For this purpose it is much better than the carbonate, which is not well borne by the stomach when continued for any length of time.

POTASSÆ CITRAS. *U. S., Br. Citrate of Potassa.*

"Take of Citric Acid *ten troyounces;* Bicarbonate of Potassa *fourteen troyounces;* Water *a sufficient quantity.* Dissolve the Citric Acid in two pints of Water, add the Bicarbonate gradually, and, when effervescence has ceased, strain the solution and evaporate to dryness, stirring constantly, after a pellicle has begun to form, until the salt granulates. Then rub it in a mortar, pass it through a coarse sieve, and keep it in a well-stopped bottle." *U. S.*

"Take of Carbonate of Potash *eight ounces* [avoirdupois], or *a sufficiency;* Citric Acid, in crystals, *six ounces* [avoird.], or *a sufficiency;* Distilled Water *two pints* [Imperial measure]. Dissolve the Citric Acid in the Water, add the Carbonate of Potash gradually, and, if the solution be not neutral, make it so by the cautious addition of the Acid or the Carbonate of Potash. Then filter, and evaporate to dryness, stirring constantly, after a pellicle has begun to form, till the salt granulates. Triturate in a dry, warm mortar, and preserve the powder in stoppered bottles." *Br.*

Citrate of potassa was first recognised as officinal in the U. S. Pharmacopœia of 1850. It was known formerly by the name of *salt of Riverius.* In the above U. S. formula, mutually saturating proportions of the acid and bicarbonate were intended to be employed; the latter ingredient being preferred to the carbonate on account of its greater purity. The potassa of the bicarbonate unites with the citric acid, to form the citrate of potassa, and the carbonic acid escapes, producing effervescence. The resulting solution is directed to be evaporated to dryness, as affording the most convenient form for use. The granulation ordered has a tendency to retard the deliquescence of the citrate. The British process differs only in the use of the carbonate instead of bicarbonate, and by providing more carefully for an exact neutralization.

Citrate of potassa is crystallizable, but, as procured by the above process, is in the form of a white granular powder. It is inodorous, of a saline, slightly bitterish, not unpleasant taste, deliquescent, very soluble in water without residue, and insoluble in alcohol. It is stated in the U. S. Pharmacopœia that its solution does not change the colour of litmus; but we have found a carefully prepared specimen slightly to redden the paper; and the acid used in the process is theoretically in slight excess. By a red heat, with exposure to the air, the salt is decomposed, leaving a residue of pure carbonate of potassa. The presence of tartaric acid would be indicated by a precipitate of bitartrate of potassa on the addition of muriatic acid.

The British Pharmacopœia gives the following tests of its character. Heated with sulphuric acid it forms a brown fluid, and gives off inflammable vapours with the odour of acetic acid. Its solution, mixed with a solution of chloride of calcium, remains clear till it is boiled, when a white precipitate is formed readily soluble in acetic acid. This is a character of citric acid, which, in saline combination, unites with lime to form the insoluble citrate only when heated. Acidulated with hydrochloric acid, the solution gives a yellow precipitate with bichloride of platinum; showing that the base of the salt is potassa. When 102 grains are heated to redness till gas is no longer evolved, an alkaline residue (carbonate of potassa) is left, which requires for exact saturation 100 measures of the *volumetric solution of oxalic acid.*

As citric acid is tribasic, this salt consists of three eqs. of potassa and one of acid; its formula being $3KO,C_{12}H_5O_{11}$.

Medical Properties. Citrate of potassa is a grateful refrigerant diaphoretic, and has long been used in the fevers of this country, in the extemporaneous forms of neutral mixture and effervescing draught. As these require time and a somewhat careful manipulation in their preparation, it has been found more convenient to keep the citrate of potassa ready made, and dissolve it in water when wanted for use. This solution will no doubt produce the essential diaphoretic

and refrigerant effects of the neutral mixture or effervescing draught; but is less agreeable to the stomach and palate, because destitute of the carbonic acid contained in these preparations. The dose of the citrate is from twenty to twenty-five grains. (See *Liquor Potassæ Citratis*, p. 1216.) W.

POTASSÆ ET SODÆ TARTRAS. *U. S.* SODÆ ET POTASSÆ TARTRAS. *Br.*, *U. S.* 1850. *Tartrate of Potassa and Soda. Tartrate of Soda and Potash. Tartarized Soda. Rochelle Salt.*

"Take of Carbonate of Soda *twelve troyounces;* Bitartrate of Potassa, in fine powder, *sixteen troyounces;* Boiling Water *five pints.* Dissolve the Carbonate of Soda in the Water, and gradually add the Bitartrate of Potassa. Filter the solution, and evaporate until a pellicle begins to form; then set it aside to crystallize. Pour off the mother-water, and dry the crystals on bibulous paper. Lastly, evaporate the mother-water, that it may furnish more crystals." *U. S.*

"Take of Acid Tartrate of Potash, in powder, *sixteen ounces* [avoirdupois], or *a sufficiency;* Carbonate of Soda *twelve ounces* [avoird.], or *a sufficiency;* Boiling Distilled Water *four pints* [Imperial measure]. Dissolve the Carbonate of Soda in the Water, add gradually the Acid Tartrate of Potash, and, if after being boiled for a few minutes the liquid has an acid or alkaline reaction, add a little Carbonate of Soda or Acid Tartrate of Potash till a neutral solution is obtained. Boil and filter; concentrate the liquor till a pellicle forms on the surface, and set it aside to crystallize. More crystals may be obtained by again evaporating as before." *Br.*

This is a double salt, consisting of tartrate of potassa combined with tartrate of soda; or, if the bibasic view of tartaric acid is accepted, a tartrate of potassa and soda, as its name imports, consisting of one eq. of tartaric acid with one of each of the alkalies. The theory of its formation is very simple, being merely the saturation of the excess of acid in the bitartrate of potassa by the soda of the carbonate of soda, the carbonic acid of which escapes with effervescence. The quantities of the materials for mutual saturation are 143·3 parts of carbonate and 188·2 of bitartrate, or one eq. of each. This gives the ratio of 3 to 3·95. The proportion adopted in the U. S. and Br. Pharmacopœias is as 3 to 4, which is very near the theoretical quantities. As the salts employed are apt to vary in composition and purity, the carbonate from the presence of more or less water of crystallization, and the bitartrate from containing tartrate of lime, it is, perhaps, best in all cases, after indicating the nearest average proportion as a general guide, to present to the operator the alternative of using the cream of tartar to the point of exact saturation.

Properties. Tartrate of potassa and soda is in the form of colourless, transparent, slightly efflorescent crystals, often very large, and having the shape, when carefully prepared, of right prisms, with ten or twelve unequal sides. As ordinarily crystallized, they are generally in half prisms, as if split in the direction of their axis. The salt has a saline and slightly bitter taste. It dissolves in 2·5 parts of cold water, and in much less boiling water. Any undissolved residue is impurity, probably tartrate of lime or bitartrate of potassa, or both. Its solution is neutral to test paper, and yields no precipitate with chloride of barium, or a dilute solution of nitrate of silver. The non-action of these tests shows the absence of sulphates and chlorides. When the salt is exposed to a strong heat, it blackens, and gives out inflammable gases with the odour of burnt sugar; the tartaric acid being destroyed, and a mixture of the carbonates of potassa and soda left. It sometimes contains tartrate of lime, which may be removed by solution and crystallization; but, when the crystals are large and well defined, it may be assumed to be pure. It is incompatible with most acids, and with all acidulous salts except bitartrate of potassa. It is also decomposed by the acetate and subacetate of lead, by the soluble salts of lime, and by those

of baryta, unless the solution of the tartrate be considerably diluted. The way in which acids act in decomposing it, is by combining with the soda, and throwing down bitartrate of potassa as a crystalline precipitate. This double salt was discovered by Seignette, an apothecary of Rochelle, and hence is frequently called *Seignette's salt*, or *Rochelle salt.*

Composition. Tartrate of potassa and soda consists of two eqs. of tartaric acid 132, one of potassa 47·2, one of soda 31·3, and eight of water 72 = 282·5; or, considered as a double salt, of one eq. of tartrate of potassa 113·2, and one of tartrate of soda 97·3, with the same quantity of water. If tartaric acid is bibasic, it must be considered as consisting, the eight eqs. of water being left out of the question, of one eq. of each of its other three constituents, the equivalent of the acid being doubled. Forty-seven grains of it, thoroughly incinerated, leave sufficient of the two alkaline carbonates to neutralize 30 measures of the *volumetric solution of oxalic acid. (Br.)*

Medical Properties and Uses. This salt is a mild, cooling purgative, well suited to delicate and irritable stomachs, being among the least unpalatable of the neutral salts. As it is not incompatible with tartar emetic, it may be associated with that salt in solution. It is an ingredient in the effervescing aperient called Seidlitz powders. (See *Pulveres Effervescentes Aperientes.*) The dose as a purge is from half an ounce to an ounce. Given in small and repeated doses it does not purge, but is absorbed, and renders the urine alkaline. (Millon and Laveran, *Journ. de Pharm.*, 3*e sér.*, vi. 222.)

Tartrate of potassa and magnesia, formed by saturating cream of tartar with carbonate of magnesia, has been proposed by M. Maillier as a safe and pleasant purgative. (*Journ. de Pharm.*, xiii. 252.)

Off. Prep. Pulveres Effervescentes Aperientes, *U. S.* B.

POTASSÆ TARTRAS. *U. S.*, *Br.* *Tartrate of Potassa. Soluble Tartar.*

"Take of Carbonate of Potassa *sixteen troyounces;* Bitartrate of Potassa [cream of tartar], in fine powder, *thirty-six troyounces*, or *a sufficient quantity;* Boiling Water *eight pints.* Dissolve the Carbonate of Potassa in the Water; then gradually add Bitartrate of Potassa to the solution until it is completely saturated, and boil. Filter the liquid, evaporate it until a pellicle forms, and set it aside to crystallize. Lastly, pour off the mother-water, and, having dried the crystals on bibulous paper, keep them in a well-stopped bottle." *U. S.*

"Take of Acid Tartrate of Potash *twenty ounces* [avoirdupois], or *a sufficiency;* Carbonate of Potash *nine ounces and a quarter* [avoird.], or *a sufficiency;* Boiling Distilled Water *two pints and a half* [Imperial measure]. Dissolve the Carbonate of Potash in the Water; add by degrees the Acid Tartrate of Potash, and if, after a few minutes' boiling, the liquid is not neutral to test paper, make it so by the careful addition of more of the Carbonate or of the Acid Tartrate. Then filter, concentrate till a pellicle forms on the surface, and set it aside to cool and crystallize. More crystals may be obtained by evaporating and cooling the mother-liquor. Drain the crystals, dry them by exposure to the air in a warm place, and preserve them in a stoppered bottle." *Br.*

In these processes, the excess of acid in the bitartrate is saturated by the potassa of the carbonate, the carbonic acid is extricated with effervescence, and the neutral tartrate of potassa is formed. On account of the greater solubility of the carbonate than of the bitartrate, the former is first dissolved, and the latter added to the solution to full saturation. As the bitartrate is gradually added, the mutual action of the salts should be promoted by constant stirring, and the addition continued so long as effervescence takes place, which is a better mode of proceeding than to add any specified quantity of the bisalt; since, from its variable quality, it is impossible to adjust precisely the proportions applicable to all cases. It is necessary that the solution should be exactly neutral,

or a little alkaline; and hence, if inadvertently too much bitartrate has been used, the proper state may be restored by adding a little of the alkaline carbonate. When the saturation has been completed, the solution is filtered in order to separate tartrate of lime, which appears in white flocks, and which is always present in cream of tartar as an impurity. The evaporated liquor should then be placed in *warm* earthenware vessels, to ensure a slow refrigeration; and, after remaining at rest for several days, the crystals begin to form. In order that the crystallization should proceed favourably, it is necessary, according to Baumé, that the solution should be somewhat alkaline. Iron vessels should not be used in any part of the process; as this metal is apt to discolour the salt.

Tartrate of potassa is sometimes made in the process for preparing tartaric acid. When thus obtained, the excess of acid of the bitartrate is neutralized by means of carbonate of lime. This generates an insoluble tartrate of lime, and leaves the neutral tartrate in solution, from which it may be obtained by evaporation and crystallization. (See *Acidum Tartaricum.*)

Properties, &c. Tartrate of potassa, prepared according to the officinal processes, is in white crystals, which are neutral to test paper, slightly deliquescent, and usually in the form of irregular six-sided prisms with dihedral summits. Its taste is saline and bitter. It dissolves in its own weight of cold, and in half its weight of boiling water (*Wittstein*), and is nearly insoluble in alcohol. Exposed to heat it undergoes fusion, swells up, blackens, and is decomposed; being converted into carbonate of potassa. For medical use it should be crystallized; but, as it ordinarily occurs in the shops, it is a white granular powder, obtained by evaporating the solution to dryness, while it is constantly stirred. In this state it is said to require four times its weight of water for solution. It is not known to be purposely adulterated; but, if obtained by evaporation to dryness, it is liable to contain an excess of carbonate or bitartrate of potassa, when it will have either an alkaline or acid reaction. It is decomposed by all the strong acids, and by many acidulous salts, which cause the precipitation of minute crystals of bitartrate of potassa, by abstracting one eq. of alkali from two of the salt. Chloride of barium or acetate of lead occasions a white precipitate of tartrate of baryta or lead, distinguishable from the sulphate of those bases by being wholly soluble in dilute nitric acid. Tartrate of potassa is composed of one eq. of potassa 47·2, and one of tartaric acid 66 = 113·2, or, if tartaric acid be considered as bibasic, of two eqs. of base 94·4 and one of acid 132 = 226·4. According to Berzelius, the crystals contain no water of crystallization.

Medical Properties. Tartrate of potassa is a mild, cooling purgative, operating, like most of the neutral salts, without much pain, and producing watery stools. It is applicable to febrile diseases, and is occasionally combined with senna, the griping effects of which it has a tendency to obviate. The dose is from a drachm to an ounce, according to the degree of effect desired. B.

POTASSII BROMIDUM. *U. S.*, *Br.* *Bromide of Potassium.*

"Take of Bromine *two troyounces;* Iron, in the form of Filings, *a troyounce;* Pure Carbonate of Potassa *two troyounces and sixty grains;* Distilled Water *four pints.* Add the Iron, and afterwards the Bromine, to a pint and a half of the Distilled Water, stirring the mixture frequently with a glass rod for half an hour. Apply a gentle heat, and, when the liquid assumes a greenish colour, add gradually the Pure Carbonate of Potassa, previously dissolved in a pint and a half of the Distilled Water, until it ceases to produce a precipitate. Continue the heat for half an hour, and then filter. Wash the precipitate with the remainder of the Distilled Water, boiling hot, and again filter. Mix the filtered liquids, and evaporate that crystals may form. Lastly, pour off the mother-water, and, having dried the crystals on bibulous paper, keep them in a well-stopped bottle." *U. S.*

"Take of Solution of Potash *two pints* [Imperial measure]; Bromine *four fluidounces* [Imp. meas.], or *a sufficiency;* Wood Charcoal, in fine powder, *two ounces* [avoirdupois]; Boiling Distilled Water *one pint and a half* [Imp. meas.]. Put the Solution of Potash into a glass or porcelain vessel, and add the Bromine in successive portions, with constant agitation, until the mixture has acquired a permanent brown tint. Evaporate to dryness; reduce the residue to a fine powder, and mix this intimately with the Charcoal. Throw the mixture in small quantities at a time into a red-hot iron crucible, and, when the whole has been brought to a state of fusion, remove the crucible from the fire, and pour out its contents. When the fused mass has cooled dissolve it in the Water, filter the solution through paper, and set it aside to crystallize. Drain the crystals, and dry them with a gentle heat. More crystals may be obtained by evaporating the mother-liquor and cooling. The salt should be kept in a stoppered bottle." *Br.*

In the first step of the U. S. process, a solution of bromide of iron is formed; and this, by the addition of the solution of carbonate of potassa, is decomposed so as to generate carbonate of the protoxide of iron which precipitates, and bromide of potassium in solution. By straining, the precipitated carbonate is separated, and from the strained liquor crystals of bromide of potassium are obtained by due evaporation. In the Br. process, by reaction between potassa and bromine, the bromide of potassium and bromate of potassa are produced in solution, and, having been obtained dry by evaporation, are exposed with the powder of charcoal to a red heat, whereby the bromate of potassa is converted into bromide of potassium by the separation of its oxygen. The remainder of the process consists in obtaining the bromide in crystals by solution in boiling water, which deposits it on cooling.

Properties, &c. Bromide of potassium is a permanent, colourless, anhydrous salt, crystallizing in cubes or quadrangular prisms, and having a pungent, saline taste, similar to that of common salt, but more acrid. It is very soluble in cold water, more so in hot, and but slightly soluble in alcohol. When heated it decrepitates, and, at a red heat, fuses without decomposition. If its aqueous solution be mixed with a little chlorine water, and then shaken with ether, the bromine, separated by the chlorine, will be dissolved by the ether, which will rise to the surface of a red colour. The salt may thus be known to be a bromide. That the base is potassium may be known by the white crystalline precipitate produced by tartaric acid added to its solution. The following characters are given of the salt in the U. S. Pharmacopœia. "Its aqueous solution does not affect the colour of litmus or turmeric, and is not precipitated by chloride of barium. When mixed with starch and treated with sulphuric acid, it becomes yellow. The salt, when subjected to heat, does not lose weight. Ten grains of it require, for complete precipitation, 14·30 grains of nitrate of silver; and the precipitate formed has a yellowish colour." The object of adding sulphuric acid with the starch, is to set the bromine free. If iodine be set free at the same time, the starch will assume a violet or feeble blue colour. To test for iodine in this salt, Lassaigne recommends to add to its solution a few drops of chlorine water, and then to introduce a piece of starched white paper. If iodine be present, the starch will become violet, or faintly blue; and iodide of potassium, which is not an unfrequent impurity, may thus be detected. If the salt decomposes more nitrate of silver than is above stated, its saturating power is greater than it should be, and the presence of a chloride, probably of potassium or sodium, may be suspected. Chlorides may be more certainly detected by precipitating the salt with nitrate of silver, and treating the precipitate with a slight excess of ammonia. If there be a chloride, the chloride of silver will be thrown down, to be dissolved by the ammonia; and the solution thus obtained, if treated with nitric acid in excess, will throw down a white precipitate of chloride of silver. (*Journ. de Pharm.*, Dec. 1863, p. 514.) An iodide of an alkaline metal will be detected by adding

to the solution of the bromide the chloride of palladium, which will precipitate all the iodine in the form of iodide of palladium, while the bromide of that metal will remain in solution. (*Ibid.*) Bromide of potassium consists of one eq. of bromine 78·4, and one of potassium 39·2 = 117·6.

Medical Properties. Bromide of potassium is alterative and resolvent, and is thought to be sedative to the nervous system and powerfully antaphrodisiac. In 1828, Pourché used it with benefit, both internally and in the form of ointment, in the treatment of bronchocele and scrofula. Favourable results were obtained by the late Dr. T. Williams, of London, from its use as an internal remedy in enlarged spleen, and it has been given advantageously in goitre. According to Ricord, it produces effects in secondary syphilis similar to those of iodide of potassium, but acts more slowly. The same view is taken of its slow action in syphilis by Dr. John Egan. This surgeon, after experimenting with bromide of potassium for four years in the Westmoreland Lock Hospital, found its effects, in secondary and tertiary syphilis, slow and unsatisfactory, when compared with those of the iodide. While the latter generally increased the appetite and improved digestion, the bromide not unfrequently produced nausea and derangement of the digestive organs. M. Huette, from extensive trials of the remedy in the same stages of syphilis, found it inefficacious; exhibiting, in its effects, a marked contrast to iodide of potassium, which rapidly relieved the cases in which the bromide had failed. (*Ann. de Thérap.*, 1851, p. 216.) Given in large doses (from two to five drachms daily), it produces headache, followed by a peculiar intoxication, with torpor and drowsiness, slowness of the pulse, temporary dulness of sight and hearing, and weakness of the intellectual faculties. In one case, observed by M. Rames, the insensibility was so complete that the puncture of the skin with a suture needle was not felt, and the titillation of the conjunctiva and fauces with a feather produced neither winking nor desire to vomit. (*Journ. de Pharm.*, Dec. 1849.) Anæsthesia of the fauces, produced by the bromide, was subsequently observed by M. Huette, who also noticed in it the property of inducing more or less torpidity of the genital organs. Its powers as an antaphrodisiac have been confirmed by Dr. Thielmann, of St. Petersburg, M. Trousseau, of Paris, and subsequently by many others. Sir Charles Locock has used it advantageously in hysterical epilepsy, and other nervous affections connected with uterine disorder. Dr. Garrod has found it powerfully sedative to the sexual function, and recommends it strongly in nymphomania, priapism, certain forms of menorrhagia, and even in ovarian tumours. (*Med. Times and Gaz.*, March, 1864, p. 276.) It is efficacious in the painful erections occurring in gonorrhœa; and has been much used, with supposed advantage, in spermatorrhœa. Dr. J. Jones, of London, has found it very effectual in certain infantile convulsions, given in the dose of two or three grains every four or six hours. (*Ibid.*, p. 254.) By M. Ozanam, of Paris, it has been successfully used in fourteen cases of pseudo-membranous affections, two of which were croup. It has been given with good effect by Mr. Spencer Wells, of London, in cancerous tumours, in the dose of from five to ten grains, with one, two, or three drachms of cod-liver oil, three times a day. (*Ibid.* July, 1857, p. 31.) In reference to its anæsthetic action on the fauces, it has been usefully employed in examination of these parts, and in operations upon them.

Bromide of potassium may be given in the form of pill, or dissolved in water, in doses of from three to ten grains three times a day. When used as an antaphrodisiac, the dose is two or three grains every two hours. The *ointment* may be made by mixing from a scruple to two drachms of the bromide with an ounce of lard. Of this from half a drachm to a drachm may be rubbed on a scrofulous tumour, or other part where its local action is desired, once in twenty-four hours. Sometimes bromine is added to this ointment in the proportion of thirty minims to the ounce of lard. B.

POTASSII CYANIDUM. *U. S.* POTASSII CYANURETUM. *U. S.* 1850. *Cyanide of Potassium. Cyanuret of Potassium.*

"Take of Ferrocyanide of Potassium, dried, *eight troyounces;* Pure Carbonate of Potassa, dried, *three troyounces.* Mix the salts intimately, and throw the mixture into a deep iron crucible previously heated to redness. Maintain the temperature until effervescence ceases, and the fused mass concretes, of a pure white colour, upon a warm glass rod dipped into it. Then pour out the liquid carefully into a shallow dish to solidify, ceasing to pour before the salt becomes contaminated with the precipitated iron. Break up the mass while yet warm, and keep the pieces in a well-stopped bottle." *U. S.*

The above process for obtaining this cyanide, which is that of F. & E. Rodgers, though generally known under the name of Liebig, was substituted, in the U. S. Pharmacopœia of 1850, for the process in which the ferrocyanide is ignited without addition. It furnishes a large product, but a considerable part of it is the impurity, cyanate of potassa. The reaction takes place between two eqs. of ferrocyanide of potassium and two of carbonate of potassa. The iron is set free, the carbonic acid evolved, and a compound of five eqs. of cyanide of potassium and one of cyanate of potassa is formed. The iron occupies the lower part of the fused liquid; and, if the latter be carefully poured out to solidify, the portion contaminated with the iron may be left behind. The reaction is explained by the following equation: $2(2KCy,FeCy)$ and $2(KO,CO_2) = 5KCy$ and KO,CyO and $2Fe$ and $2CO_2$. Dr. Wittstein gives the reaction differently, to explain the larger proportion of cyanate of potassa formed than the above equation calls for. He conceives that the product consists of seven eqs. of cyanide of potassium, and three of cyanate of potassa. MM. Fordos and Gélis, in an able paper contained in the *Journ. de Pharmacie* for Aug. 1857, have pointed out numerous causes which concur in rendering the salt, as obtained by the use of carbonate of potassa, impure. The commercial cyanide, which is obtained by this process, was found by these writers to be very impure, only containing from 36 to 55 per cent. of the pure salt. The cyanate of potassa may be readily detected by saturating the product with an acid, which will cause an effervescence of carbonic acid, and the generation of a salt of ammonia. According to Dr. Schwarz, it may be freed from cyanate and carbonate of potassa, by treating the impure cyanide with bisulphuret of carbon, which dissolves it, and may be recovered in great measure by distillation. (*Chem. News*, No. 190, p. 41.)

In the process in which the ferrocyanide of potassium is ignited alone (former U. S. process), the salt is first deprived of its water of crystallization by exposure to a moderate heat, and then calcined at a red heat for two hours, in order to decompose the cyanide of iron. The product of the calcination is a black, porous mass, consisting of cyanide of potassium, mixed with carburet of iron and charcoal. As the cyanide is very prone to absorb oxygen, especially when hot, whereby it is decomposed, atmospheric air is excluded from the retort while it is cooling, by luting its orifice. When the whole is cold, the black mass is reduced to coarse powder, and exhausted by cold distilled water, which dissolves the cyanide of potassium, and leaves the carburet of iron and charcoal behind. The filtered liquor, therefore, is an aqueous solution of cyanide of potassium, which is obtained in a solid state by a rapid evaporation to dryness. During the evaporation, a small portion of the cyanide is decomposed, attended with the evolution of ammonia, and the production of formiate of potassa. A portion of this salt, therefore, contaminates the cyanide, as obtained by this process; but the quantity is too small to interfere with its medicinal action. The decomposition here referred to takes place between one eq. of cyanide of potassium and four of water, and is represented by the following equation, in which the cyanogen is expressed by its full symbol NC_2, and formic acid by C_2HO_3: K,NC_2 and $4HO = NH_3$ and KO,C_2HO_3. This decomposition is avoided by exhausting

the black mass with boiling alcohol of 60 per cent. (sp. gr. 0·896) instead of with water. The alcoholic solution, by evaporation to a pellicle, lets fall the salt upon cooling, as a crystalline precipitate, perfectly white and pure.

According to the process of the French Codex, which is that of Robiquet, this cyanide is obtained in the dry way, without the use of any solvent. The calcination is performed in a coated stoneware retort, half-filled with the ferrocyanide, to which a tube is attached for collecting the gaseous products. When these cease to be disengaged, the heat is gradually raised to a very high temperature, at which it is kept for a quarter of an hour; after which the tube is closed with luting, and the whole left undisturbed until quite cold. When the calcination is thus conducted, the retort, upon being broken, will be found to contain a black matter, covered with a fused layer of pure cyanide of potassium, resembling white enamel. This is detached by means of a knife, and immediately transferred to a bottle, with an accurately fitting stopper. The black matter, under the name of *black cyanide of potassium*, is also kept for medicinal use; but the dose of this cannot be accurately fixed, on account of its containing, at different times, more or less impurity.

According to MM. Fordos and Gélis, the French Codex process should supersede the carbonate of potassa process; as it gives a product far purer, and in larger proportion to the materials employed, estimated by the pure product. The same process is preferred by Mr. Donovan, who has modified it by substituting, for the stoneware retort, an iron mercury bottle, which, when cold, must be cut in two by a chisel and hammer to get out the product. The same recommendation of iron in preference to stoneware vessels, is made by Fordos and Gélis, who found that the latter, at the high heat employed, were acted on.

The process of Wiggers consists in disengaging hydrocyanic acid from a mixture of ferrocyanide of potassium and sulphuric acid, and passing it into a cooled receiver, containing an alcoholic solution of hydrate of potassa. The contents of the receiver ultimately form a solid magma of the cyanide, which is drained, washed several times with strong alcohol, pressed between folds of bibulous paper, and dried as quickly as possible.

Cyanide of potassium may be formed by passing a current of strongly heated nitrogen over charcoal, impregnated with carbonate of potassa, and heated to white redness. (See *page* 686.)

Properties. Cyanide of potassium, as prepared by the U. S. formula, is in white, opaque, amorphous masses, having a sharp, somewhat alkaline and bitter-almond taste, and an alkaline reaction. If yellow it contains iron. It is deliquescent in moist air, readily soluble in water when reduced to powder, and sparingly soluble in strong alcohol. Its solution effervesces with acids. The salt and its solution, when exposed to the air, exhale the odour of hydrocyanic acid, and become weaker; but the change takes place slowly. Orfila found that the salt, after fourteen days' exposure, by which it was almost entirely liquefied, still possessed energetic poisonous properties. He thinks, therefore, that the bad effects of opening the containing bottle, in dispensing the medicine, have been exaggerated. Unfortunately, the salt varies in quality, independently of the effects of time and exposure. Dr. David Stewart, of Baltimore, examined six samples of this cyanide, on sale, and found them to vary considerably in purity. Besides water, the usual impurities are hydrate, carbonate, cyanate, and formiate of potassa. They sometimes amount to half the weight of the cyanide, consisting principally of the carbonate. From the extensive use at present made of cyanide of potassium in electro-metallurgy and photography, it is of importance to have a reliable test of its purity. Such a test has been discovered by MM. Fordos and Gélis, founded on the fact that two eqs. of iodine rapidly react with one of the cyanide, so as to form a colourless compound, consisting of one eq. of iodide of potassium, and one of iodide of cyanogen: KCy and 2I = KI and CyI. Accordingly, a tincture

of iodine of known strength is gradually added to an aqueous solution of a given weight of the cyanide to be tested, until it assumes a permanent yellowish tinge; and the amount of iodine expended indicates the proportion of cyanide in the specimen. A necessary preliminary step, before using the tincture, is to add sufficient carbonic acid water to the solution of the cyanide, to convert any hydrate or carbonate of potassa present into bicarbonate, in which state neither has any action on the iodine. (*Chem. Gaz.*, Oct. 15, 1852, p. 387.) This test is applicable to other cyanogen compounds. (See *page* 926.) Mr. Thornton J. Herapath's test for commercial cyanide of potassium is a standard solution of ammonio-sulphate of copper, the blue colour of which is destroyed by a solution of the cyanide. The copper solution is added to one of the cyanide of known strength, until a faint blue coloration is produced; and the richness of the sample in pure cyanide is in proportion to the quantity of the copper solution required. (*Chemist*, April, 1856, and Feb. 1857.) Applying this test to five samples, Mr. Herapath found the proportion of pure cyanide to vary from 41 to 65 per cent. Cyanide of potassium yields with nitrate of silver a precipitate of cyanide of silver, which is wholly soluble in ammonia. It consists of one eq. of cyanogen 26, and one of potassium 39·2=65·2.

Medical Properties. Cyanide of potassium is pre-eminently poisonous, acting precisely like hydrocyanic acid as a poison and as a medicine. (See *Acidum Hydrocyanicum Dilutum.*) Since the tenth edition of this work was published, three fatal cases of poisoning by this salt have occurred in the United States. The first case, reported by Dr. C. E. Ware, of Boston, was that of a woman who took, by mistake, a teaspoonful of a solution, containing about seven grains of the salt. The second and third cases occurred in Baltimore, and arose from the mistake of an apothecary in putting up cyanide of potassium for chlorate of potassa in a mixture. A dose of the mixture destroyed a child, and, likewise, the apothecary, who, to show his confidence in the correctness with which it had been compounded, swallowed a portion of it himself. Hydrocyanic acid has been detected in the blood of a person who had been fatally poisoned by the cyanide (Venghauss, *Arch. der Pharm.*, clii. 138.) The grounds on which this cyanide was proposed as a substitute for hydrocyanic acid by Robiquet and Villermé, were its uniformity as a chemical product, and its less liability to undergo decomposition. The dose is the eighth of a grain, dissolved in half a fluidounce of distilled water, to which may be added half a fluidrachm of syrup of lemons, if the prescriber wish to set the hydrocyanic acid free. The spurious cyanide, formed by calcining dried muscular flesh with potash, consists principally of carbonate of potassa, and is but slightly poisonous. (*Orfila.*) A solution of cyanide of potassium, made with from one to four grains to the fluidounce of water, has been recommended in neuralgic and other local pains, applied by means of pieces of linen. Mr. Guthrie found that a solution of from three to six grains to the fluidounce of distilled water, formed an admirable remedy, applied by drops every other day, for removing the olive-coloured stains of the conjunctiva caused by nitrate of silver. B.

POTASSII IODIDUM. *U. S., Br. Iodide of Potassium.*

"Take of Potassa *six troyounces;* Iodine, in fine powder, *sixteen troyounces*, or *a sufficient quantity;* Charcoal, in fine powder, *two troyounces;* Distilled Water *a sufficient quantity*. To the Potassa, dissolved in three pints of Distilled Water, boiling hot, gradually add the Iodine, stirring after each addition until the solution becomes colourless, and continue the additions until the liquid remains slightly coloured from excess of Iodine. Evaporate the solution to dryness, stirring in the Charcoal towards the close of the operation, so that it may be intimately mixed with the dried salt. Rub this to powder, and heat it to dull redness in an iron crucible, maintaining that temperature for fifteen minutes; then, after it has cooled, dissolve out the saline matter with Distilled Water, filter the

solution, evaporate, and set it aside to crystallize. An additional quantity of crystals may be obtained from the mother-water by evaporating and crystallizing as before." *U. S.*

"Take of Solution of Potash *one gallon* [Imperial measure]; Iodine, in powder, *twenty-nine ounces* [avoirdupois], or *a sufficiency;* Wood Charcoal, in fine powder, *three ounces* [avoird.]; Boiling Distilled Water *a sufficiency.* Put the Solution of Potash into a glass or porcelain vessel, and add the Iodine in small quantities at a time with constant agitation, until the solution acquires a permanent brown tint. Evaporate the whole to dryness in a porcelain dish, pulverize the residue, and mix this intimately with the Charcoal. Throw the mixture, in small quantities at a time, into a red-hot iron crucible, and, when the whole has been brought to a state of fusion, remove the crucible from the fire and pour out its contents. When the fused mass has cooled, dissolve it in two pints [Imp. meas.] of boiling Distilled Water, filter through paper, wash the filter with a little boiling Distilled Water, unite the liquids, and evaporate the whole till a film forms on the surface. Set it aside to cool and crystallize. Drain the crystals, and dry them quickly with a gentle heat. More crystals may be obtained by evaporating the mother-liquor and cooling. The salt should be kept in a stoppered bottle." *Br.*

In these processes, which are essentially the same, an aqueous solution of potassa is treated with iodine in slight excess. The result of thus saturating potassa with iodine is the formation of two salts, iodide of potassium and iodate of potassa. Six eqs. of iodine react with six of potassa, and there are formed five eqs. of iodide of potassium, and one of iodate of potassa ($6KO$ and $6I = 5KI$ and KO,IO_5). By evaporating the solution to dryness the mixed salts are obtained; and, if the dry mass be exposed to a red heat, the iodate will be converted into iodide of potassium, thus removing this impurity from the iodide. In the formula the mixed salts, towards the close of their evaporation to dryness, are directed to be mixed with powdered charcoal, according to the plan of Mr. Scanlan, which facilitates the deoxidation of the iodate. This being accomplished by a dull red heat, the iodide of potassium is dissolved out of the mass, and the solution set aside to crystallize.

In the late Ed. and Dub. processes the first step was to form iodide of iron in solution, precisely as is done in the formula for that compound; and the second to decompose it by carbonate of potassa, which gave rise to iodide of potassium in solution, and a precipitate of carbonate of protoxide of iron. The solution of iodide of potassium was separated by filtration and washing from the precipitated carbonate, and evaporated to dryness. The dry salt was then freed from iron and other impurities by solution in boiling water or alcohol, filtration, and crystallization. Messrs. T. and H. Smith, of Edinburgh, instead of washing the precipitate, prefer the plan of pressing it strongly in a cloth, in order to extract the remains of the solution. The mass left is broken up in a portion of distilled water equal to about two-thirds of the weight of the iodine employed, and pressed a second time. Proceeding thus, less water is used, and less evaporation is necessary. The solution obtained by them is evaporated to dryness, and the dry salt is carefully fused in an iron pot, in order to free it from colour. It is then dissolved, and the solution, by filtration, concentration, and cooling, furnishes a perfectly pure iodide nearly to the last.*

* For formulas by Prof. Mayer, of New York, for the preparation of the iodides and bromides, based on the reaction between iodine or bromine on the one hand, and iron and bicarbonate of potassa or the carbonate of soda, lithium, or lime, according to the particular iodide wanted, on the other, see the *Am. Journ. of Pharm.* (July, 1862, p. 292). Another process of Liebig, as detailed by Mr. Squire, will be found in the same journal for Sept. 1862 (p. 437). To 1 part of phosphorus covered with 40 parts of water, 20 parts of iodine are gradually added; the solution of phosphoric and hydriodic acids thus obtained

Properties, &c. Iodide of potassium, sometimes incorrectly called *hydriodate of potassa*, is in opaque, white or transparent crystals, permanent in a dry air, slightly deliquescent in a moist one, and having a sharp saline taste. It does not change the colour of litmus, and has little or no effect on turmeric. According to the Messrs. Smith, of Edinburgh, it is not at all deliquescent when perfectly pure. It generally crystallizes in cubes. It is soluble in about two-thirds of its weight of cold water, and in from six to eight parts of rectified spirit. If solution of iodide of potassium be mixed with solution of starch, and a minute quantity of solution of chlorine be added, a blue colour will be produced; the chlorine combining with the potassium and thus liberating the iodine which forms a blue compound with starch. Its solution is decomposed by the addition of a few drops of sulphuric acid, hydriodic acid being generated, which speedily undergoes decomposition, with evolution of iodine; and, if starch be added after the lapse of a few minutes, a blue colour is produced. The starch test will not give the characteristic blue colour immediately, if added simultaneously with the acid, unless the iodide of potassium contains iodate of potassa, which impurity causes an immediate liberation of iodine. The blue colour being produced by the starch and acid, if simultaneously added, is, therefore, a sign of impurity. A very delicate test of iodide of potassium, and other soluble iodides, is that of M. Grange. It consists in pouring a little of the liquid to be examined into a test tube, adding a few drops of solution of starch, and passing through the mixture a few bubbles of fuming nitrous acid. The liquid immediately assumes a pale-rose colour, inclining to violet, when containing 1-200,000th of its weight of the iodide, and a bright-blue colour, if 1-100,000th is present. (See *page* 471.) "When tartaric acid is freely added to a strong solution of the iodide, it occasions a white crystalline precipitate; and the supernatant liquid, if mixed with starch, becomes first purple, and finally blue. Bichloride of platinum colours its solution reddish-brown, without causing a precipitate; chloride of barium but slightly affects it; and sulphate of iron occasions no change." (*U. S.*) The non-action of the last test shows the absence of carbonate of potassa. The aqueous solution is capable of taking up a large quantity of iodine, forming a liquid of a deep-brown colour.

Exposed to a dull red heat iodide of potassium fuses, and on cooling concretes into a crystalline pearly mass, without loss of weight; but at a full red heat it is slowly volatilized without decomposition. The most usual impurities contained in this salt are the chlorides of potassium and sodium, bromide of potassium, and carbonate and iodate of potassa. The presence of a chloride may be determined by nitrate of silver. This test will throw down nothing from the pure salt but iodide of silver, which is scarcely soluble in ammonia; while chloride of silver is readily soluble in it. If then a solution of the iodide be precipitated by an excess of nitrate of silver, and agitated with ammonia, the latter will dissolve any chloride which may have been thrown down, and will yield it again as a white precipitate on being saturated with nitric acid. If, on the other hand, the iodide of potassium be pure, the ammonia will take up only a minute quantity of iodide of silver, and the addition of nitric acid will scarcely disturb the transparency of the solution. The iodide of silver precipitated from 10 grains of iodide of potassium weighs, when washed and dried, 14·1 grains.

is poured off, and milk of lime added in slight excess; the whole is placed upon a filter, and the precipitate, consisting of phosphate of lime, is pressed and washed; the filtrate, containing only iodide of calcium, is boiled down, with 12 parts of powdered sulphate of potassa, to about one-half; the whole, after standing six hours, is filtered, and the precipitate pressed as before; a little pure carbonate of potassa is added to the filtrate to remove every trace of lime; and the filtered solution, containing only iodide of potassium, yields that salt in crystals by concentration. By slight modifications of the process, the iodides of sodium, lithium, and various other metals may be obtained.—*Note to the twelfth edition.*

When acetate of lead is added to a solution of iodide of potassium, a yellow precipitate of iodide of lead is thrown down, soluble in boiling water. The low price of bromide of potassium, compared with that of the iodide, has caused the former to be used to adulterate the latter. When bromide of potassium is sold for the iodide, the fraud may be detected by the fact that the addition of sulphuric acid produces copious reddish fumes, instead of the purple ones, arising from the iodide. In order to detect bromine, M. Personne first precipitates from an aqueous solution of the suspected iodide, the whole of the iodine as protiodide of copper, by successively adding, in excess, a solution of sulphate of copper, and aqueous sulphurous acid; and then treats the filtered liquid with ether and chlorine water, the whole being shaken together and left at rest. If bromine be present, the ether which rises to the surface will be tinged of a reddish-yellow colour. Carbonate of potassa may be discovered by lime-water, which causes a milkiness (carbonate of lime), and by tincture of iodine, the colour of which is destroyed. The Br. Pharmacopœia admits a slight degree of this impurity, directing that lime-water should only faintly precipitate the solution. The iodate may be detected by adding a solution of tartaric acid to a solution of the suspected iodide. Bitartrate of potassa will be precipitated, and, if the iodide be pure, a yellow colour is *soon* developed by the action of the air on the liberated hydriodic acid; but, if any iodate be present, the test will give rise to both iodic and hydriodic acids, which, by their mutual action, will *instantly* develope iodine.

Mr. William Copney has pointed out an excellent test for detecting carbonate and iodate of potassa, in the use of protiodide of iron, in the form of syrup of iodide of iron, recently prepared. (See *Syrupus Ferri Iodidi.*) A drop of the syrup is added to a solution of the suspected iodide of potassium. A bluish precipitate indicates the carbonate; a red one, the iodate; and a blue precipitate, followed by a red one, both impurities. Carbonate of potassa is generally present in the proportion of from 1 to 10 per cent. Dr. Christison has detected 74½ per cent., and Dr. Pereira as high as 77 per cent. An adulteration by the carbonate under 10 per cent. does not alter the crystalline appearance of the iodide, but gives it an increased tendency to deliquesce. When it is greater it renders the salt granular and highly deliquescent. As iodide of potassium is soluble in rectified spirit, anything left undissolved by that menstruum is impurity. The amount of impurity in this salt, without ascertaining its nature, may be determined by the method of Marozeau, which consists in adding a solution of corrosive sublimate to one of the iodide to be examined, the salts being taken in the proportion of four eqs. of the iodide to one of the bichloride. If the iodide be pure, its excess will be just competent to redissolve all the red iodide of mercury formed by the addition of the corrosive sublimate solution. If impure, a reddish colour from undissolved red iodide will appear before the whole of the latter solution is added. Accordingly, if a solution of one eq. of corrosive sublimate be gradually added to a solution of four eqs. of the iodide, until the reddish colour ceases to disappear upon stirring, the proportion expended will represent the pure iodide, and that unexpended, the impurity in the specimen examined. (See the paper of Mr. J. M. Maisch, in the *Am. Journ. of Pharm.*, xxvi. 293.) Iodide of potassium consists of one eq. of iodine 126·3, and one of potassium 39·2 = 165·5. It contains no water of crystallization.

Prof. Procter has given a paper on the incompatibles of iodide of potassium in relation to the mercurial preparations. He finds it incompatible with calomel, the black and red oxides of mercury, turpeth mineral, white precipitate, blue mass, and metallic mercury. These experiments serve to confirm the observation of M. Melsens, that iodide of potassium, given in connection with the insoluble preparations of mercury, renders them soluble and much more active. (See *Am. Journ. of Pharm.*, xxvi. 222.) With nitrous ether iodide of potassium reacts, yielding, among other products, hydriodic ether and a little ordinary

ether. (Juncadella, *Comptes Rendus*, Fev. 1859, p. 345.) At ordinary temperatures iodide of potassium is slowly decomposed, with evolution of iodine, by nitrate of ammonia and boracic acid; and, at high temperatures, in a glass test tube, with escape of violet vapours, not only by the two substances just named, but also by sulphate, oxalate, carbonate, and muriate of ammonia, sulphate, phosphate, nitrate, and borate of soda, sulphates of potassa and magnesia, nitrate of lime, chlorides of sodium, potassium, and calcium, and silicic acid. (Ubaldini, *Journ. de Pharm.*, Oct. 1859, p. 292.)

Medical Properties, &c. The general therapeutic properties of the preparations of iodine, of which iodide of potassium is the most important, have been given under the head of iodine. By most practitioners the preparation under notice is preferred for producing the constitutional effects of iodine. It certainly produces very marked effects on the secretions, which it uniformly increases, and into which it readily passes. It has a tendency to irritate the mucous membrane of the air-passages, as shown by its sometimes occasioning an affection like cold in the head. When long continued in large doses, it occasionally produces a tender, enlarged, lobulated, and fissured tongue, constituting a true chronic glossitis. Mr. Langston Parker, of England, has reported several cases of this kind, in which the iodide had been taken for years. Its obvious effects on the system are very variable, arising probably either from peculiarities of constitution, or from the unequal quality of the medicine itself. Thus it produces nausea, pain in the stomach, and diarrhœa, in moderate doses, in some cases; and is borne in large doses without inconvenience in others. It generally increases the appetite and flesh. The general character of its action is to remove abnormal tissue, eliminating the material for the most part by the channel of the kidneys. There are but few diseases in which it has not been tried. Its use in scrofulous affections, combined with iodine, has been explained under the head of iodine. It has been recommended by M. Oke in chorea, after the preparations of iron have failed; by M. Gendrin, Dr. Clendenning, and Mr. Spencer Wells in gout; by M. Arrigan in albuminuria; by Mr. Sankey in ague, given in large doses; and by MM. Demarquay and Gustin in stomatitis. The latter writers think it more efficacious in this disease than chlorate of potassa.

Dr. Williams, of London, considers it applicable to the treatment of various forms of secondary syphilis. He used it with success, in a majority of cases, in removing hard periosteal nodes, and found it beneficial in the treatment of tubercular forms of venereal eruptions. It is also considered as one of the best alterative remedies in mercurio-syphilitic sorethroat. Ricord bears testimony to its valuable powers in the treatment of secondary syphilis. Dr. Handfield Jones found it particularly efficacious in that form of rheumatism characterized by wandering pains in the bones. According to the clinical observations of Dr. W. R. Basham, iodide of potassium is well suited to the treatment of chronic periosteal rheumatism in subjects who have previously taken mercury to salivation; while it is not applicable to the disease when occurring in patients who have not undergone a mercurial course, but have suffered from syphilis, which has been neglected, or treated only locally. In the latter cases he conceives that corrosive sublimate and sarsaparilla are the proper remedies. It is probably useful in the former cases on the principle of eliminating mercury from the system, agreeably to the views of M. Melsens, given below. In 1843 MM. Guillot and Melsens gave iodide of potassium with advantage, in doses of from a drachm to a drachm and a half daily, in mercurial tremors and lead poisoning. In a memoir published in 1849, M. Melsens gives a full account of his experiments with it as a remedy for the affections caused by mercury and lead. He effected a number of cures of mercurial tremors and lead palsy; and, during the progress of the cure, these metals were found in the urine. The manner in which the remedy acts, according to M. Melsens, is by rendering the poisonous metal, which has become

fixed in the tissues, soluble, first converting it into an iodide, and then dissolving the iodide formed. This view is supported by the fact that all the compounds of mercury and lead are soluble in iodide of potassium.*

The views and results of M. Melsens have been confirmed by therapeutic trials in lead poisoning by M. Malherbe, of Nantes, and by Drs. Parke and Sieveking, of London. An important fact observed by M. Melsens was that iodide of potassium, given at the same time with certain compounds of mercury, rendered them more active; and, when given after them, developed an activity not previously manifested, and sometimes to such an extent as to occasion serious accidents. This fact he explained by referring it to the power of the iodide to render the mercurial compounds soluble, in which state only are they capable of being eliminated with the urine. During the use of iodide of potassium, ptyalism sometimes occurs. This has been usually considered a primary effect of the remedy; but the light shed on the subject by M. Melsens leads to the belief, that it may be a secondary effect, resulting from the liberation from the tissues of mercury previously taken, which is thereby enabled, by becoming soluble, to produce its constitutional effects. Dr. Budd relates several cases, in which mercurial ptyalism came on, during the use of iodide of potassium, in persons who had not taken mercury for weeks or months before. It is probable that, in these cases, the mercury had been long lying fixed in the system, and was rendered soluble and active by the iodide.

The late Dr. Isaac Parrish, of this city, employed iodide of potassium successfully in strumous inflammation of the eye, given in the compound syrup of sarsaparilla. It appeared promptly to relieve the severe neuralgic, circumorbital pain. Dr. Griscom, also of this city, cured a case of supposed membranous croup in a child by the use of this remedy, after leeches, sinapisms, warm baths, and emetics had failed. (*Trans. of the Coll. of Phys. of Philad.*, N. S., ii. 164.) Dr. De Renzy, of Carnew, Ireland, found it efficacious in hæmoptysis. Dr. G. L. Upshur, of Virginia, recommends its use in the suppurative stage of pneumonia.

The dose of iodide of potassium is from two to ten grains or more, three times a day, given in dilute solution. Ricord rarely exceeded three scruples a day. Some practitioners have employed enormous doses, such as two, four, and even six drachms daily without inconvenience. Dr. Buchanan, of Glasgow, assures us that he has given the pure salt in doses of half an ounce, without any precaution being observed by the patient, except to drink freely of diluents. Notwithstanding this testimony, Dr. Lawrie, of the same city, reports several cases of dryness and irritation of the throat, ending in severe spasmodic croup, and one case of death following the sudden occurrence of dyspnœa, caused by the use of this iodide, even when given in small doses. According to Dr. Gull, of London, the efficiency of the remedy is much increased by uniting it with carbonate of ammonia, in the proportion of two or three grains of the iodide to four or five of the carbonate.

Iodide of potassium passes quickly into the urine, in which it may be detected by first adding to the cold secretion a portion of starch, and then a few drops of nitric acid, when a blue colour will be produced. It has been detected in six minutes after having been swallowed. According to Schottin it passes slowly into the sweat. Taken in half-drachm doses daily, it did not appear in that secretion until five days had elapsed.

According to Ricord, this salt produces in some constitutions peculiar effects; such as eruptions of the skin, excessive diuresis, vascular injection of the conjunctiva and tumefaction of the eyelids, cerebral excitement like that produced by alcoholic drinks, and discharges from the urethra and vagina, resembling

* See the Memoir of M. Melsens, translated by Dr. Budd, of Bristol, England, in the *Brit. and For. Medico-Chir. Review*, Am. ed., for Jan. 1853, p. 157; also a paper by Dr. J. W Corson, in the *N. Y. Journ. of Med.* for Sept. 1853.

blennorrhœa. Eruptions of the skin were also observed by Dr. A. Van Buren, as a very common effect of large and long-continued doses of iodide of potassium, given to patients in the Bellevue Hospital, N. Y. Dr. John O'Rielly, of New York, reports several cases, in which, after the use of this iodide, spots like purpura were produced, invading first the face, and then the trunk and extremities. These became bullæ, sometimes an inch in diameter, filled with a purple liquid, and finally sphacelated spots ending in ulcers. Great constitutional disturbance coexisted, with swollen tongue, fetor, and salivation. The remedies found successful were nutritious diet, tonics, and stimulants. From the facts above mentioned, showing the power of iodide of potassium to render active mercury that is latent in the system, it is not improbable that the cases of Dr. O'Rielly were mercurial salivation, modified by a cachectic condition of the system, which caused the coincident eruption.

Iodide of potassium is employed as an external application in the form of ointment, either alone or mixed with iodine. (See *Unguentum Potassii Iodidi* and *Unguentum Iodinii Compositum.*)

Off. Prep. Hydrargyri Iodidum Rubrum; Linimentum Iodi, *Br.;* Liquor Iodinii Compositus, *U. S.;* Plumbi Iodidum, *U. S.;* Tinctura Iodi, *Br.;* Tinctura Iodinii Composita, *U. POTASSII SULPHURETUM. *U. S.* POTASSA SULPHURATA. *Br. Sulphuret of Potassium. Sulphurated Potassa. Liver of Sulphur.*

"Take of Sublimed Sulphur *a troyounce;* Carbonate of Potassa *two troyounces.* With the Sulphur rub the Carbonate, previously dried, and heat the mixture gradually in a covered crucible until it ceases to swell, and is completely melted. Then pour out the liquid on a marble slab, and, when the mass is cold, break it into pieces, and keep these in a well-stopped bottle of green glass." *U. S.*

"Take of Carbonate of Potash, in powder, *ten ounces;* Sublimed Sulphur *four ounces and a half.* Mix the Carbonate of Potash and the Sulphur in a warm mortar, and, having introduced them into a Cornish or Hessian crucible, let this be heated, first gradually, until effervescence has ceased, and finally to deep redness, so as to produce perfect fusion. Let the liquid contents of the crucible be then poured out on a clean flagstone, and covered quickly with an inverted porcelain basin, so as to exclude the air as completely as possible, while solidification is taking place. The solid product thus obtained should, when cold, be broken into fragments, and immediately enclosed in a green-glass bottle, furnished with an air-tight stopper." *Br.*

These processes are essentially the same, except that a greater heat is used in the Br. process, which somewhat modifies the result. When carbonate of potassa is melted with half its weight of sulphur, as in the U. S. process, the carbonic acid is expelled. The explanation heretofore given is as follows. Four eqs. of potassa and ten of sulphur may be supposed to react on each other. Three eqs. of potassa are decomposed into three eqs. of potassium and three of oxygen. The three eqs. of potassium unite with nine eqs. of sulphur to form three eqs. of tersulphuret of potassium. The three eqs. of oxygen, by uniting with the remaining eq. of sulphur, form one eq. of sulphuric acid, which combines with the undecomposed eq. of potassa to form sulphate of potassa. Thus, the preparation may be considered to be a mixture of tersulphuret of potassium with sulphate of potassa; and the French Codex sulphuret, made from the same proportion of carbonate and sulphur, is stated in that work to have the same composition. The fact is, however, that the composition varies with the heat employed. If the heat do not exceed 365° F., the resulting preparation will contain hyposulphite of potassa; if above 572° F., sulphate of potassa. (*Fordos and Gélis.*) The U. S. preparation, therefore, which is made at the temperature of fusion, probably contains hyposulphite of potassa, and may be represented

by the formula $2KS_3+KO,S_2O_2$; three eqs. of CO_2 escaping: while the British, being prepared at a red heat, contains sulphate of potassa, with the formula $3KS_3+KO,SO_3$; four eqs. of CO_2 escaping.

The Pharmacopœias use the carbonate of potassa from pearlash; but in the process of M. Henry, which is stated to be the best yet devised, the pure carbonate of potassa is employed. His formula is as follows. Mix two parts of real salt of tartar with one of roll sulphur reduced to powder, and put the mixture into flat-bottomed matrasses, which should be only two-thirds filled. These are placed on a sand-bath, and the fire is applied so as, at first, to produce only a gentle heat, which is afterwards increased. Care must be taken that the necks of the matrasses do not become obstructed. The heat is continued, until the matter is brought to the state of tranquil fusion, when it is allowed to cool. The mass obtained, which is compact, smooth, and of a fine yellow colour, is broken into pieces, and preserved in well-stopped bottles.

Properties, &c. Sulphuret of potassium, when properly prepared, is a hard, brittle substance, having a nauseous, alkaline, and bitter taste. Its colour is liver-brown, and hence its name of *hepar sulphuris* or *liver of sulphur*. The colour of the surface of a fresh fracture is brownish-yellow. It is inodorous when dry, but emits a slightly fetid smell when moist, owing to the extrication of a little sulphuretted hydrogen gas. It is soluble in water, forming an orange-yellow liquid, and exhaling the smell of sulphuretted hydrogen. By exposure to the air it attracts oxygen, and the sulphuret of potassium is gradually changed into sulphate of potassa, when the preparation becomes inodorous, and white on the surface. The solution is decomposed by the mineral acids, which extricate sulphuretted hydrogen, and precipitate the excess of sulphur. It is also incompatible with solutions of most of the metals, which are precipitated as sulphurets. When boiled with an excess of muriatic acid and filtered, it gives a yellow precipitate with bichloride of platinum, and a white one with chloride of barium. The preparation of the Br. Pharmacopœia yields about three-fourths of its weight to alcohol; the portion dissolved being sulphuret of potassium, and the undissolved portion sulphate of potassa. B.

Medical Properties and Uses. Sulphuret of potassium is a local irritant, and, in small and repeated doses, is said to increase the frequency of the pulse, heat of the skin, and different secretions, especially the mucous. Occasionally it vomits and purges. It acts, moreover, as an antacid, and produces the alterative effects of sulphur. By some it is maintained to be sedative, and directly to reduce the action of the heart. It probably does so, when taken in considerable quantities, by the development of sulphuretted hydrogen. In overdoses it acts, according to Orfila, as a violent poison, corroding the stomach, and depressing the powers of the nervous system. Acetate of lead or acetate of zinc may be used as an antidote; but the latter is preferable, as less likely to act injuriously in an overdose, and having besides emetic properties. The complaints in which it has been most advantageously employed are chronic rheumatism and gout, and various cutaneous affections. It has been given also in painters' colic, asthma, and chronic catarrh, and acquired a short-lived reputation as a remedy in croup, after the publication of the essay in which the prize offered by Napoleon for the best dissertation on that disease was awarded. It is said, in some cases of cancer, to have assisted the palliative operation of hemlock. In consequence of forming insoluble sulphurets with the metallic salts, it has been proposed as an antidote for some mineral poisons; but Orfila has shown that it does not prevent their effects. Dissolved in water it has proved efficacious as an external application in cutaneous diseases, and in scabies is an almost certain remedy. It may be used for this purpose in the form of lotion, bath, or ointment. For a lotion it may be dissolved in water in the proportion of from fifteen to thirty grains to the fluidounce, and for a bath the same quantity or rather more may be added

to a gallon of water. A very small proportion of muriatic or sulphuric acid may in either case be added to the solution. The ointment is made by mixing half a drachm of the sulphuret with an ounce of lard. The dose of sulphuret of potassium is from two to ten grains, repeated several times a day, and given in pill with liquorice, or in solution with syrup. In infantile cases of croup, from one to four grains were given every three or four hours. W

PULVERES.

Powders.

The form of powder is convenient for the exhibition of substances which are not given in very large doses, are not very disagreeable to the taste, have no corrosive property, and do not deliquesce rapidly on exposure. As the effect of pulverization is to expose a more extended surface to the action of the air, care should be taken to keep substances which are liable to be injured by such exposure in closely-stopped bottles. In many instances it is also important to exclude the light, which exercises a deleterious influence over numerous medicines when minutely divided. This may be done by coating the bottles with black varnish. In relation to substances most liable to injury from these causes, the best plan is to powder them in small quantities as wanted for use.*

Powders may be divided into the *simple*, consisting of a single substance, and the *compound*, of two or more mixed together. The latter only are embraced under the present head. In the preparation of the compound powders, the ingredients, if of different degrees of cohesion or solidity, should be pulverized separately and then mixed. An exception, however, is when one substance is employed to facilitate by its hardness the minute division of another, as in the *powder of ipecacuanha and opium*. Deliquescent substances, and those containing fixed oil in large proportion, should not enter into the composition of powders intended to be kept; the former because they render the preparation damp and liable to spoil; the latter, because they are apt to become rancid, and impart an unpleasant odour and taste. When deliquescent substances are extemporaneously prescribed, the apothecary should enclose them before delivery in tin foil or other impervious covering; and the same remark is applicable to volatile powders, as carbonate of ammonia and camphor.

The lighter powders may in general be administered in water or other thin liquid; the heavier, such as those of metallic substances, require a more consistent vehicle, as syrup, molasses, honey, or one of the confections. Resinous powders, if given in water, require the intervention of mucilage or sugar.

The whole substance in the mortar should not be beaten till completely pul-

* In contradiction to what has been stated in the text in relation to keeping powders in well-stopped bottles, it is asserted by M. Hérouard, a French pharmaceutist, that this plan, instead of preserving powders, tends in fact to their more speedy and certain change. Whatever pains may be taken in drying medicines previously to powdering them, most of them during the process attract moisture, so as to put themselves in this respect in equilibrium with the surrounding air; and, if enclosed in this state in air-tight vessels, they are exposed to injurious influence from their own absorbed water, which, vaporized in hot weather, is in the colder seasons condensed on the inner surface of the vessel, and determines a movement of fermentation; and even cryptogamic growths appear. The best method of preservation, the author thinks, is to enclose the powders in strong paper bags of a blue or gray colour, so as to exclude the light, while the air has exit or entrance through the porous walls. But whatever may be our theoretical opinions on the point, M. Hérouard asserts the fact, as the result of observation, that powders keep best in this way. They may be more likely to cake or harden into aggregate masses; but this disadvantage is easily counteracted by a new pulverization when required. There is probably much truth in these statements; and the inference may at least be drawn, that, where powders are kept in air-tight bottles, they should be thoroughly dried, after pulverization, before being enclosed. (*Journ. de Pharm.*, Août, 1862, p. 98.)—*Note to the twelfth edition.*

verized; as the portion already powdered interferes with the action of the pestle upon the remainder, while the finer matter is apt to be dissipated; so that there is a loss both of time and material. The proper plan is to sift off the fine powder after a short trituration, then to return the coarser parts to the mortar, and to repeat several times this alternate pulverization and sifting, until the process is completed. Care should be taken to mix thoroughly the several portions of fine powder thus obtained.*

The preparations of this class, which have been dismissed at the recent revision of the Pharmacopœias, are the *Compound Powder of Aloes*, Lond., the *Compound Powder of Alum*, Ed.; and the *Citrated Effervescing Powders*, Ed. W.

PULVERES EFFERVESCENTES. *U. S.* *Effervescing Powders. Soda Powders.*

"Take of Bicarbonate of Soda, in fine powder, *three hundred and sixty grains;* Tartaric Acid, in fine powder, *three hundred grains.* Divide each of the powders into twelve equal parts, and keep the parts, severally, of the Bicarbonate and of the Acid in separate papers of different colours." *U. S.*

This is a formula, introduced into the present edition of our national Pharmacopœia, for a preparation which has been long in use under the name of *soda powders*. The powders consist, severally, of twenty-five grains of the acid in one paper, and thirty of the bicarbonate in the other. They are administered in solution. An acid and an alkaline powder may be dissolved in separate portions of water and then mixed; or they may be thrown together, or successively into the same portion of water. The whole draught should be half a pint or somewhat less. It may be rendered more agreeable by adding two or three fluidrachms of syrup of ginger or orange peel to the water, before dissolving the

* *Granulated Powders.* A new method of preparing powders for use has lately been introduced, consisting in converting them into minute granules, such as those of which salt of tartar consists, and of which there have long been a few examples, in which the object was to obviate change from atmospheric influence by diminishing the surface of exposure. In the new *granulated powders*, not only is the advantage arising from mere aggregation of particles gained, but the granules are further protected against change by receiving a distinct coating, which, being generally saccharine, has the additional advantage that it covers the taste of the powders, and much facilitates their administration. Placed on the tongue in quantities, less or more, they may be swallowed without difficulty, by simply washing them down with a little water; or they may be stirred up with water in a wineglass, and then swallowed.

Dr. Thos. Skinner, in a paper contained in the *Pharmaceutical Journal* (May, 1862, p. 572), gives the following plan of preparing these granulated powders, suggested by Mr. S. Banner, of Liverpool. The powder to be granulated should be freshly prepared. In general it is not at all necessary that it should be so fine as to be impalpable. The powder is first mixed in a mortar with enough mucilage of gum arabic to make a mass that will easily crumble; or it may be made into a plastic mass, which is to be rolled into thin cakes, and dried. The material is then to be broken up in a mortar, and sifted. For this purpose three sieves are required, with 12, 16, and 20 meshes, respectively, to the inch: which are to be fitted together, one over the other, the coarsest at top and the finest at bottom. The broken up mass is put in the upper sieve, and rubbed through by the open hand; the conjoined sieves are then shaken as in sifting; and, this part of the process being completed, they are separated. The larger granules are found in the middle sieve, the smaller in the lowermost, and the waste powder on a leather or parchment drum beneath. This waste is to be worked over again. The two sizes of granules are kept apart. If not already dry, as they always are when the material is first made into cakes, they are to be carefully dried; and are next put into a mortar, and, a strong tincture of tolu (ʒiij to fʒi), aromatized if desired, having been added, are stirred constantly till their surface appears glossy; after which they are again dried, and thus prepared for use. The proportion of gum used is about one-sixteenth of the weight of the granules, that of Tolu balsam too small to be worth estimating.

In France the granular powders are usually made with the addition of sugar, which, if in fixed proportion, as one to one, or one to two, can be of no inconvenience in relation to the estimation of the dose.—*Note to the twelfth edition.*

powders. The rationale is simple. The tartaric acid seizes the alkali of the bicarbonate, forming a tartrate of soda, while the carbonic acid escapes with effervescence. The effervescing powders are refrigerant and slightly laxative; and afford an agreeable and refreshing drink, suitable to febrile complaints, and generally very acceptable to the stomach. W.

PULVERES EFFERVESCENTES APERIENTES. *U. S. Aperient Effervescing Powders. Seidlitz Powders.*

"Take of Bicarbonate of Soda, in fine powder, *a troyounce;* Tartrate of Potassa and Soda, in fine powder, *three troyounces;* Tartaric Acid, in fine powder, *four hundred and twenty grains.* Mix intimately the Bicarbonate of Soda with the Tartrate of Potassa and Soda, and divide this mixture into twelve equal parts. Then divide the Tartaric Acid into the same number of equal parts. Lastly, keep the parts, severally, of the mixture and of the Acid in separate papers of different colours." *U. S.*

These powders, so long and so usefully employed under the name of *Seidlitz powders*, have for the first time found a place among officinal preparations in the present edition of the U. S. Pharmacopœia. Though named from the saline springs of Seidlitz, in Bohemia, they do not correspond in composition with those famous waters. Of each pair of powders, one, much the smaller of the two, contains thirty-five grains of tartaric acid, the other forty grains of bicarbonate of soda mixed with two drachms of Rochelle salt. The acid powder is usually put into a white, the alkaline into a blue paper; and a number of them are enclosed in a paper or tin box. They should not be kept in a damp place, as the tartaric acid is liable to be dissolved by the moisture, and absorbed into the substance of the paper; thus altering the due proportion of the ingredients. We have known the whole of the contents of the white paper thus to disappear in the course of two or three years. In such a case, however, the paper itself may be torn up and put into the water, to which it soon imparts the acid. The Rochelle salt is the ingredient upon which the aperient property mainly depends. In their administration, each powder is dissolved separately, the smaller in a fluidounce or more of water, the larger in twice or three times the quantity; and the two solutions are mixed gradually. A reaction takes place between the tartaric acid and the bicarbonate of soda, by which tartrate of soda is produced, adding somewhat to the laxative property of the draught, and carbonic acid escapes, causing a brisk effervescence. The acid is in slight excess, and thus causes an agreeable acidity in the solution. These powders are refrigerant and aperient, and generally very acceptable to the stomach in consequence of the carbonic acid eliminated. They are especially adapted to febrile cases with a somewhat irritable stomach. One pair of them will generally operate slightly; but, if required, two may be given at once; or the dose may be repeated every three or four hours till the desired effect is produced. The flavour may sometimes be advantageously improved by adding syrup of ginger, orange peel, or lemon to one of the solutions before admixture. W.

PULVIS ALOËS ET CANELLÆ. *U. S. Powder of Aloes and Canella. Hiera Picra.*

"Take of Socotrine Aloes, in fine powder, *twelve troyounces;* Canella, in fine powder, *three troyounces.* Rub them together until they are thoroughly mixed." *U. S.*

This preparation has long been known under the name of *hiera picra.* The canella serves to correct the griping property, and imperfectly to cover the taste of the aloes; but the bitterness of the latter is still very obvious in the mixture, which would be better given in the form of pill. It is a popular remedy in amenorrhœa, and may be used for all the purposes to which aloes is applied. It is

sometimes administered in domestic practice, infused in wine or spirit. The dose is from ten to twenty grains. W.

PULVIS AMYGDALÆ COMPOSITUS. *Br.* CONFECTIO AMYGDALÆ. *Lond.* CONSERVA AMYGDALARUM. *Ed.* *Compound Powder of Almonds.*

"Take of Jordan Almonds *eight ounces;* Refined Sugar, in powder, *four ounces;* Gum Arabic, in powder, *one ounce.* Steep the Almonds in cold water until their skins can be easily removed; and, when blanched, dry them thoroughly with a soft cloth, and rub them lightly in a mortar to a smooth consistence. Mix the Gum and the Sugar; and, adding them to the pulp gradually, rub the whole to a coarse powder. Keep it in a lightly-covered jar." *Br.*

This is nothing more than the old *Almond Confection* under a new name. It is intended to afford a speedy method of preparing the almond mixture, which, when made immediately from the almonds, requires much time, and which cannot be kept ready made in the shops. But, from its liability to be injured by keeping, it was omitted from our Pharmacopœia, which directs the almond mixture to be made immediately from the ingredients.

Off. Prep. Mistura Amygdalæ, *Br.* W.

PULVIS ANTIMONIALIS. *Br.* *Antimonial Powder.*

"Take of Oxide of Antimony *one ounce;* Precipitated Phosphate of Lime *two ounces.* Mix them thoroughly." *Br.*

This preparation has been introduced into the British Pharmacopœia as a substitute for the different forms of antimonial powder formerly officinal with the British Colleges. In order that the subject may be properly understood, it will be necessary to introduce a notice of the powder as formerly directed to be prepared by the London and Dublin Colleges; the process of the Edinburgh College having been so similar to the London, that it does not require special consideration.

Antimonial Powder of the London College. The following was the London process. "Take of Tersulphuret of Antimony, powdered, *a pound;* Horn Shavings *two pounds.* Mix, and throw them into a red-hot crucible, and stir constantly until vapour ceases to arise. Rub the residue to powder, and put it into a crucible. Then apply heat, and raise it gradually to redness, and keep it so for two hours. Rub the remaining powder until it is as fine as possible." *Lond.*

This preparation consists mainly of bone-phosphate of lime, or calcined bone, mixed with antimonious acid, and is intended to furnish a substitute for the celebrated nostrum of Dr. James, an English physician who died in 1776, and after whom the original preparation was called *James's powder.* Dr. Pearson, of London, found the genuine powder, on analysis, to consist of phosphate of lime and oxidized antimony, and, guided by his results, devised the formula adopted by the London College. By burning the materials directed by the College, the sulphur is expelled in the form of sulphurous acid, and the antimony oxidized; while the horn, which is of the nature of bone, has its animal matter converted into charcoal. By the subsequent calcination the charcoal is dissipated, leaving only the phosphate of lime of the horn mixed with the oxidized antimony.

The antimonial powder made by this formula is a tasteless, inodorous, gritty powder, of a dull-white colour. As often prepared it is insoluble in water; but usually a small portion, consisting of antimonite and superphosphate of lime, dissolves in boiling distilled water. Its composition varies exceedingly, a circumstance which forms a strong objection to it as a medicine. When entirely insoluble in boiling water, it probably contains nothing but antimonious acid and phosphate of lime; for, when its soluble constituents are absent, the teroxide is absent also. The best samples consist of "a mixture chiefly of antimonious acid and phosphate of lime, with some sesquioxide [teroxide] of antimony, and a little antimonite of lime." (*Ed.*) To these ingredients may be added superphosphate

of lime, which was found in small quantity by Dr. D. Maclagan, of Edinburgh. This writer obtained in his experiments about 50 per cent. of antimonious acid, 45 of phosphate of lime, nearly 4 of teroxide, and not quite one of antimonite and superphosphate of lime. The antimonial powder, sold by the representatives of Dr. James, is more active, and more uniform in its effects, than the imitation powder of the Pharmacopœias; its greater activity being explained by the presence of a greater proportion of teroxide, which Dr. Maclagan found to vary from 4 to 10 per cent. In analyzing the London antimonial powder, the first step is to act on it with boiling distilled water. If any antimonite should be dissolved, the solution will form with sulphuretted hydrogen an orange-coloured precipitate of quadrisulphuret of antimony; if superphosphate be present, nitrate of silver will throw down phosphate of silver. What remains of the powder, unacted on by the distilled water, is next digested with muriatic acid, which will dissolve the phosphate of lime, and also teroxide of antimony if present, and leave a residue which is the antimonious acid. If teroxide be present in the muriatic solution, it will be precipitated by sulphuretted hydrogen, as an orange-coloured tersulphuret, and from the filtered solution, water of ammonia will throw down the phosphate of lime. In this way all the ingredients of antimonial powder may be detected and separated. It might be supposed that the muriatic solution would be more readily tested for teroxide by means of water, which causes a white precipitate of oxychloride in this solution; but there seems to be some ambiguity in relation to the action of water. The Edinburgh College, in its formula of tests, stated that the muriatic solution of the residue, left after the exhaustion by water, does not become turbid by dilution; but, according to Dr. Barker and Dr. Pereira, this effect sometimes takes place. These different results may be explained by the different qualities of the preparation. A small quantity of teroxide may be in the muriatic solution, and yet not be precipitated by water as oxychloride; while a larger quantity will be so precipitated. On the other hand a precipitate may be produced with water, without proving the presence of teroxide; for, unless the antimonial powder be most carefully exhausted by the distilled water before being subjected to the acid, the muriatic solution may contain antimonite of lime, which, like the teroxide, gives it the property of becoming turbid with water.

The Dublin Antimonial Powder. Influenced, apparently, by considerations such as above presented, the Dublin College contrived the following process, with the object of having a preparation of definite constitution, and of an activity to be depended on. "Take of Tartarized Antimony, Phosphate of Soda, each, *four ounces* [avoirdupois]; Chloride of Calcium *two ounces* [avoird.]; Solution of Ammonia *four fluidounces* [Imperial measure]; Distilled Water *one gallon and a half* [Imp. meas.], or *a sufficient quantity*. Dissolve the Tartarized Antimony in half a gallon, and the Phosphate of Soda and Chloride of Calcium, each, in a quart of the Water. Mix the solutions of the Tartarized Antimony and Phosphate of Soda when cold, and then pour in the solution of Chloride of Calcium, having first added to the latter the Water of Ammonia. Boil now for twenty minutes, and, having collected the precipitate, which will have then formed, on a calico filter, wash it with hot distilled water until the liquid which passes through ceases to give a precipitate with a dilute solution of nitrate of silver. Finally, dry the product by a steam or water heat, and reduce it to a fine powder." *Dub.*

This formula was a new one of the Dublin Pharmacopœia of 1850, and was an improvement on the process of Mr. Chenevix, proposed in 1801, for obtaining antimonial powder in the humid way. By this formula the liquid, resulting from mixing aqueous solutions of tartar emetic and phosphate of soda, is precipitated by a solution of chloride of calcium, previously mixed with water of ammonia. The water of ammonia throws down teroxide of antimony from the tartar emetic; and the chloride of calcium, phosphate of lime from the phosphate of soda; and

the mixed precipitate, washed, dried, and reduced to fine powder, constitutes what was the Dublin antimonial powder. It is quite a different preparation from that previously described; inasmuch as all the antimony present is in a state of teroxide. It should not have been called antimonial powder, but designated by a distinct name. The process by which it is obtained is certainly a great improvement on that usually followed. It is doubtful whether the phosphate of lime adds anything to its efficacy; and, if not, the preparation is equivalent to teroxide of antimony, used in a smaller dose.

British Antimonial Powder. The formula for this is the one given at the head of the present article. It is the preparation now officinal in Great Britain to the exclusion of the others. The only essential difference between it and the Dublin powder is that its ingredients are taken already prepared and mixed in fixed proportion, while those of the latter result simultaneously from one operation. It is of course much more easily prepared, and less liable to uncertainty from any error in the process.

Medical Properties and Uses. This preparation is stated to be alterative, diaphoretic, purgative, or emetic, according to the dose in which it is given. Until within a few years it was often prescribed in febrile diseases, with a view to its diaphoretic effect. According to Dr. A. T. Thomson, it is advantageously given in acute rheumatism, conjoined with camphor, calomel, and opium, and with calomel and guaiac in several cutaneous affections. The estimation in which this preparation is held is very various. The late Dr. Duncan, referring to the preparation of the Lond. and Ed. Colleges, characterized it as one of the best antimonials we possess; yet he acknowledged that its effects are very unequal, either from idiosyncrasy in the patient, or variations in its composition. Dr. Thomson found it sometimes to answer his expectations, but as often to disappoint them. Mr. Brande admits its activity sometimes, and entire inertness at others, which he attributes to the presence or absence of *teroxide* of antimony. Of course these observations had reference to the former antimonial powder of the British Colleges; and it was this uncertainty of its action that led to its omission from the U. S. Pharmacopœia, upon the revision of 1830.

The antimonial powder at present officinal in Great Britain is exempt from the objection of irregularity of composition. Nevertheless, as it depends for its greater or less energy on the presence or absence in the alimentary canal of an acid which may form a salt with the antimonial oxide, it cannot always be relied on for a definite effect, being sometimes mild, and sometimes more active than might be desirable. The dose, as a diaphoretic, is from three to eight grains every third or fourth hour, given in the form of pill. In larger doses it is purgative and emetic. It is impossible to give precise directions as to the dose of the former London powder; as it sometimes proved violently emetic in moderate doses, and at other times produced no obvious effect even in doses of one hundred grains.

The late *Dublin* antimonial powder, which may be considered as essentially identical with the British, was tried therapeutically in twenty cases of disease, chiefly rheumatism, pneumonia, and bronchitis, by Dr. Jonathan Osborne, of Dublin. In five-grain doses, given evening and night, it produced, variously, nausea, vomiting, and perspiration. In half the cases it acted gently on the bowels. The teroxide, given separately in three-grain doses, evening and night, produced similar effects. (*Pharm. Journ.*, Jan. 1855, p. 331.) Practitioners who may wish to prescribe the antimonial powder, in its present more certain form, should add (*Br.* or *Dub.*) to its name; so as to be secured against the old *Lond.* and *Ed.* preparation. B.

PULVIS AROMATICUS. *U. S.*, *Br.* *Aromatic Powder.*

"Take of Cinnamon, in fine powder, Ginger, in fine powder, each, *two troy-ounces;* Cardamom, deprived of the capsules and in fine powder, Nutmeg, in

fine powder, each, *a troyounce.* Rub them together until they are thoroughly mixed." *U. S.*

"Take of Cinnamon *four ounces;* Nutmeg, Saffron, each, *three ounces;* Cloves *one ounce and a half;* Cardamoms, freed from their capsules, *one ounce;* Refined Sugar *twenty-five ounces.* Reduce the ingredients separately to fine powder; mix them thoroughly, and pass the powder through a fine sieve. Keep it in a stoppered bottle" *Br.*

These powders, though each composed of the finer spices, differ not only in the choice of the spices, ginger being used in the U. S. and cloves in the Br. formula, but essentially in the circumstance that, in the latter, sugar constitutes two-thirds of the mixture, while in the former there is no sugar; so that the two powders cannot be substituted one for the other in equal quantities. In the British Pharmacopœia, the *aromatic confection* having been omitted, it is probable that the sugar was added in order that, by the addition of a little water to the powder, the confection might be readily prepared, without the necessity of keeping it.

The cardamom seeds should always be separated from their capsules before being weighed; and the powder, when prepared, should be kept in well-stopped bottles. The aromatic powder is stimulant and carminative, and the U. S. preparation may be given in the dose of from ten to thirty grains, in cases of enfeebled digestion with flatulence; but it is chiefly used as a corrigent and adjuvant of other medicines. A mixture of aromatic powders in the form of a cataplasm is much used as a mild rubefacient, especially in nausea and vomiting, being applied over the epigastrium. Such mixtures are commonly called *spiced plasters.* The following is a good formula. Take of ginger, cloves, cinnamon, and black pepper, each, in powder, an ounce; tincture of ginger half a fluidounce; honey a sufficient quantity. Mix the powders, and then add the tincture and honey, so as to form a stiff cataplasm.

Off. Prep. Confectio Aromatica, *U. S.;* Confectio Opii, *U. S.;* Pilula Cambogiæ Composita, *Br.;* Pulvis Cretæ Aromaticus, *Br.* W.

PULVIS CATECHU COMPOSITUS. *Br. Compound Powder of Catechu.*

"Take of Catechu *four ounces;* Kino, Rhatany, each, *two ounces;* Cinnamon, Nutmeg, each, *one ounce.* Reduce them separately to a fine powder; mix them thoroughly, and pass the powder through a fine sieve. Keep it in a stoppered bottle." *Br.*

This is an agreeable form for the administration of kino or catechu; but we do not see the propriety of mixing two substances so similar in their properties, at least in relation to taste and medicinal effect, that they may be considered identical. The dose is from fifteen to thirty grains. W.

PULVIS CRETÆ AROMATICUS. *Br. Aromatic Powder of Chalk.*

"Take of Prepared Chalk *one pound;* Aromatic Powder *three pounds.* Mix them thoroughly, and pass the powder through a fine sieve. Keep it in a stoppered bottle." *Br.*

This powder is a warm stimulant and astringent, as well as antacid; and is well calculated for diarrhœa connected with acidity, and without inflammation. In such a combination, however, the due proportion, and even the choice of the ingredients, vary so much with the symptoms, that they might with propriety be left to extemporaneous prescription. The dose is from thirty to sixty grains, given in mucilage or sweetened water, and frequently repeated.

Off. Prep. Pulvis Cretæ Aromaticus cum Opio. W.

PULVIS CRETÆ AROMATICUS CUM OPIO. *Br. Aromatic Powder of Chalk and Opium.*

"Take of Aromatic Powder of Chalk *nine ounces and three-quarters;*

Opium, in powder, *a quarter of an ounce.* Mix them thoroughly, and pass the powder through a fine sieve. Keep it in a stoppered bottle." *Br.*

The addition of the opium greatly increases the efficacy of the compound powder of chalk in diarrhœa; and its equal diffusion through the powder presents this advantage, that it may be conveniently given in minute doses applicable to infantile cases. Two scruples of the powder contain a grain of opium. In the diarrhœa of adults from ten to twenty grains may be given for a dose, and repeated several times a day, or after each evacuation. W.

PULVIS IPECACUANHÆ COMPOSITUS. *U. S.* Pulvis Ipecacuanhæ cum Opio. *Br.* Pulvis Ipecacuanhæ et Opii. *U. S.* 1850. *Compound Powder of Ipecacuanha. Powder of Ipecacuanha and Opium. Dover's Powder.*

"Take of Ipecacuanha, in fine powder, Opium, dried and in fine powder, each, *sixty grains;* Sulphate of Potassa *a troyounce.* Rub them together into a very fine powder." *U. S.*

The British Pharmacopœia directs the same ingredients in the same proportions, and orders them to be well rubbed together, the powder to be passed through a fine sieve, and to be kept in a stoppered bottle.

It is unfortunate that, in the recent revisions of our own and the British Pharmacopœias, the name of this preparation should have been changed in each so as to conform with the old name of the other.

The sulphate of potassa in this preparation serves, by the hardness of its particles, to promote that minute division and consequent thorough intermixture of the opium and ipecacuanha upon which the peculiar virtues of the compound depend. It also serves to dilute the active ingredients, and thus allow of their division into minute doses adapted to the complaints of children. This composition, though called Dover's powder, does not precisely correspond with that originally recommended by Dr. Dover, which was prepared as follows. Four ounces of nitrate of potassa and the same quantity of sulphate of potassa were mixed in a red-hot crucible, and afterwards very finely powdered; one ounce of opium, sliced, was then added, and ground to powder with the saline mixture; lastly, an ounce of ipecacuanha and an ounce of liquorice root, in powder, were mixed with the other ingredients. This process was adopted in the former French Codex, and has been retained with little change in the present.

This powder is an admirable anodyne diaphoretic, not surpassed, perhaps, by any other combination in the power of promoting perspiration. Opium itself has a strong tendency to the skin, evinced both by the occasional diaphoresis, and by the itching and tingling sensation which it excites. While the vessels of the skin are stimulated by this ingredient, the secreting pores are relaxed by the ipecacuanha, and the combined effect is much greater than that which results from either separately. At the same time, the general stimulating influence of the opium, and its tendency to operate injuriously on the brain, are counteracted, so that the mixture may be given with safety in cases which might not admit of the use of opium alone. The preparation is applicable to all cases, not attended with much fever, cerebral disease, or sick stomach, in which there is an indication for profuse diaphoresis, especially in painful affections, or those connected with unhealthy discharges. It is admirably adapted to the phlegmasiæ, particularly rheumatism and pneumonia, when complicated with a typhoid tendency, or after sufficient depletion. Under similar circumstances, it is useful in dysentery, diarrhœa, and the various hemorrhages, especially that from the uterus. It is sometimes also given in dropsy. In bowel affections, and whenever the hepatic secretion is deranged, it is frequently combined with small doses of calomel.

Ten grains of the powder contain one grain of opium. The dose is from five

to fifteen grains, given diffused in water, or mixed with syrup, or in the form of bolus, and repeated at intervals of four, six, or eight hours, when it is desirable to maintain a continued diaphoresis. Its action may be promoted by warm drinks, such as lemonade or balm tea, which, however, should not be given immediately after the powder, as they might provoke vomiting. W.

PULVIS JALAPÆ COMPOSITUS. *U. S.*, *Br.* *Compound Powder of Jalap.*

"Take of Jalap, in fine powder, *a troyounce;* Bitartrate of Potassa, in fine powder, *two troyounces.* Rub them together until they are thoroughly mixed." *U. S.*

"Take of Jalap, in powder, *five ounces:* Acid Tartrate of Potash *nine ounces;* Ginger, in powder, *one ounce.* Rub them well together, and pass the powder through a fine sieve." *Br.*

The bitartrate, by being rubbed with the jalap, is thought to favour its more minute division, while it increases its hydragogue effect. A combination of these two ingredients, though with a larger proportion of cream of tartar (see *Jalapa*), forms a good cathartic in dropsy, and scrofulous diseases of the joints and glands. The dose of the powder is from thirty grains to a drachm. W.

PULVIS KINO CUM OPIO. *Br.* PULVIS KINO COMPOSITUS. *Lond.* *Powder of Kino and Opium.*

"Take of Kino, in powder, *three ounces and three-quarters;* Opium, in powder, *a quarter of an ounce;* Cinnamon, in powder, *one ounce.* Mix them thoroughly, and pass the powder through a fine sieve. Keep it in a stoppered bottle." *Br.*

This is an anodyne astringent powder, useful in some forms of diarrhœa, but of which the composition would be better left to extemporaneous prescription; as the proportion of the ingredients should vary with the circumstances of the case. Twenty grains contain one grain of opium. The dose is from five grains to a scruple. W.

PULVIS RHEI COMPOSITUS. *U. S.*, *Br.* *Compound Powder of Rhubarb.*

"Take of Rhubarb, in fine powder, *four troyounces;* Magnesia *twelve troyounces;* Ginger, in fine powder, *two troyounces.* Rub them together until they are thoroughly mixed." *U. S.*

"Take of Rhubarb, in powder, *two ounces:* Light Magnesia *six ounces:* Ginger, in powder, *one ounce.* Mix them thoroughly, and pass the powder through a fine sieve." *Br.*

This is a good laxative antacid, well adapted to bowel complaints, especially in children. The dose for an adult is from half a drachm to a drachm; for a child two or three years old, from five to ten grains. W.

PULVIS SCAMMONII COMPOSITUS. *Br.* *Compound Powder of Scammony.*

"Take of Scammony *four ounces;* Jalap *three ounces;* Ginger *one ounce* Reduce them separately to fine powder; mix them thoroughly, and pass the powder through a fine sieve." *Br.*

This does not appear to us a very eligible preparation. Though the ginger may tend to correct the griping property of the purgative ingredients, the jalap too closely resembles the scammony in its operation to exert any important modifying influence upon it. The dose is from ten to twenty grains. W.

PULVIS TRAGACANTHÆ COMPOSITUS. *Br.* *Compound Powder of Tragacanth.*

"Take of Tragacanth, in powder, Gum Arabic, in powder, Starch, each, *one*

ounce; Refined Sugar, in powder, *three ounces.* Rub them well together." *Br.*

This is applicable to the general purposes of the demulcents; but is chiefly employed in Great Britain as a vehicle for heavy insoluble powders. The dose is from thirty grains to a drachm. W.

QUINIA.

Preparations of Quinia.

QUINIÆ SULPHAS. *U. S., Br. Sulphate of Quinia.*

"Take of Yellow Cinchona, in coarse powder, *forty-eight troyounces;* Muriatic Acid *three troyounces and a half;* Lime, in fine powder, *five troyounces;* Animal Charcoal, in fine powder, Sulphuric Acid, Alcohol, Water, Distilled Water, each, *a sufficient quantity.* Boil the Cinchona in thirteen pints of Water mixed with one-third of the Muriatic Acid, and strain through muslin. Boil the residue twice successively with the same quantity of Water and Acid as before, and strain. Mix the decoctions, and, while the liquid is hot, gradually add the Lime, previously mixed with two pints of Water, stirring constantly, until the quinia is completely precipitated. Wash the precipitate with Distilled Water, and, having pressed, dried, and powdered it, digest it in boiling Alcohol. Pour off the liquid, and repeat the digestion several times, until the Alcohol is no longer rendered bitter. Mix the liquids, and distil off the Alcohol until a brown viscid mass remains. Upon this, transferred to a suitable vessel, pour four pints of Distilled Water, and, having heated the mixture to the boiling point, add as much Sulphuric Acid as may be necessary to dissolve the quinia. Then add a troyounce and a half of Animal Charcoal, boil the liquid for two minutes, filter while hot, and set it aside to crystallize. Should the liquid, before filtration, be entirely neutral, acidulate it very slightly with Sulphuric Acid; should it, on the contrary, change the colour of litmus paper to a bright red, add more Animal Charcoal. Separate the crystals from the liquid, dissolve them in boiling Distilled Water slightly acidulated with Sulphuric Acid, add a little Animal Charcoal, filter the solution, and set it aside to crystallize. Lastly, dry the crystals on bibulous paper with a gentle heat, and keep them in a well-stopped bottle. The mother-water may be made to yield an additional quantity of Sulphate of Quinia by precipitating the quinia with Water of Ammonia, and treating the precipitated alkaloid with Distilled Water, Sulphuric Acid, and Animal Charcoal, as before." *U. S.*

"Take of Yellow Cinchona Bark, in coarse powder, *one pound* [avoirdupois]; Hydrochloric Acid *three fluidounces* [Imperial measure]; Distilled Water *a sufficiency;* Solution of Soda *four pints* [Imp. meas.]; Dilute Sulphuric Acid *a sufficiency.* Dilute the Hydrochloric Acid with ten pints [Imp. meas.] of the Water. Place the Cinchona Bark in a porcelain basin, and add to it as much of the Dilute Sulphuric Acid as will render it thoroughly moist. After maceration, with occasional stirring for twenty-four hours, place the bark in a displacement apparatus, and percolate with the Dilute Hydrochloric Acid, until the solution which drops through is nearly destitute of bitter taste. Into this liquid pour the Solution of Soda, agitate well, let the precipitate completely subside, decant the supernatant fluid, collect the precipitate on a filter, and wash it with cold Distilled Water, until the washings cease to have colour. Transfer the precipitate to a porcelain dish containing a pint [Imp. meas.] of Distilled Water, and, applying to this a steam heat, gradually add Dilute Sulphuric Acid until very nearly the whole of the precipitate has been dissolved, and a neutral liquid has been obtained. Filter the solution while hot through paper, wash the filter with boiling Distilled Water, concentrate till a film forms on the surface of

the solution, and set it aside to crystallize. The crystals should be dried on filtering paper without the application of heat." *Br.*

The present U. S. process, which is essentially that of the French Codex, is the same as that of the Pharmacopœia of 1850, but differs from the one originally adopted in the edition of 1830, in the use of muriatic instead of sulphuric acid for acidulating the water first employed, and in the greater minuteness of the details. Both this and the French Codex process are modifications of the plan originally proposed by M. Henry, jun., of Paris, which has been almost universally employed where alcohol is not too expensive. Henry's process, with all its details, may be found in former editions of this work. An explanation of the several directions given in the U. S. Pharmacopœia will be useful to the student, by enabling him to comprehend each step of the process.

The yellow bark (Calisaya, or royal yellow) is the variety selected, because this contains quinia in the largest proportion, and most free from admixture with cinchonia. The alkaloid exists in the bark combined with kinic acid, and probably also with one or more of the colouring principles, as suggested by M. Henry. As in this latter state it is of difficult solubility, if it be not insoluble in water, the whole of the quinia cannot be extracted from the bark by means of that liquid alone. Berzelius, however, attributes the difficulty of exhausting the bark to the circumstance that water converts the native neutral kinates into soluble superkinates which are dissolved, and insoluble subkinates which remain. By adding muriatic or sulphuric acid to the water in such quantities as to be in excess in relation to the quinia, the whole of the alkaloid combines with the acid to form a very soluble muriate or sulphate, in which state it exists, together with various impurities, in the decoctions procured by the first steps of the process. By the addition of lime to the filtered and mixed decoctions, the salt of quinia is decomposed, giving up its acid to the lime, while the quinia is liberated, and, being insoluble in water, is precipitated; the water retaining most of the impurities. If sulphuric acid was employed in the commencement of the process, sulphate of lime is deposited along with the quinia; but if muriatic acid was employed, the resulting chloride of calcium is retained in solution; and a reason is thus afforded for the preference of the latter acid. But, in either case, the excess of lime, and a compound formed of the lime and colouring matter, which is insoluble both in water and alcohol, are thrown down with the alkaloid. The precipitate having been washed in order to remove from it everything soluble in water, then pressed, dried, and powdered; the next step is to separate the quinia from the insoluble impurities. This is accomplished by the repeated action of alcohol, which dissolves the former, and leaves most of the latter behind. The whole of the alkaloid having been abstracted, the alcoholic solution of quinia is then concentrated so as to afford a brown viscid mass, which is impure quinia. Portions of this may be reserved, if thought advisable, for the preparation of other salts of quinia. The mass is treated with boiling distilled water acidulated with sulphuric acid, which forms the officinal sulphate (disulphate of many chemists) with the quinia, and, being somewhat in excess, enables the salt to be readily dissolved. The animal charcoal now added should be the *unpurified* bone-black, the carbonate of lime contained in which neutralizes a portion of the sulphuric acid, and thus facilitates the crystallization of the sulphate of quinia when the solution cools. Should the quantity of the bone-black added be sufficient to render the solution quite neutral, so as in no degree to affect litmus paper, as much sulphuric acid should be added as will give the paper a slightly vinous tint; for otherwise the crystallization may commence before the liquor is completely filtered. If, on the contrary, the bone-black has been deficient, and the solution colours litmus paper cherry-red, more of that substance is to be added. This, however, is merely an incidental advantage of the animal charcoal; its chief use being to decolorize the liquid. The second crystallization is necessary to obtain the salt

of quinia free from colour; and sometimes it cannot be rendered perfectly white without a third. It is essential that the heat employed in drying the crystals should be gentle, in order to prevent their efflorescence. The small quantity of cinchonia contained in Calisaya bark is extracted along with the quinia; but, as the sulphate of the former is more soluble than that of the latter, it remains in the mother-liquors.*

According to M. Calvert, the proportion of sulphate of quinia obtained from bark is never certain when muriatic acid is employed as the solvent, and lime as the precipitant; for quinia is dissolved by a solution of chloride of calcium, and by lime-water; and a portion, therefore, remains in the liquid unprecipitated, which is greater when the lime employed is in excess. Having ascertained by trial that quinia is not dissolved by a solution of soda, and in scarcely appreciable proportion by chloride of sodium, he proposes to substitute this alkali for lime; first neutralizing the excess of acid by the carbonate, and then precipitating the quinia by caustic soda. (*Journ. de Pharm.*, 3e *sér.*, ii. 388.)

The British process seems to be based on that of M. Rabourdin, of Orleans, published in the *Journal de Pharmacie* (Juin, 1861, p. 408), for which the advantages are claimed, that it does not require the use of alcohol, escapes the loss incurred in the ordinary process by the solvent property of lime, and is enabled, by the use of soda as the precipitant, to dispense with animal charcoal, and thereby avoid the waste incurred through its absorbent property. The soda in this process is employed not only as a precipitant, for which purpose a much smaller quantity would suffice, but in order to hold in solution the tannin, cinchonic red, and colouring and resinous matters, which it does without in the least dissolving the quinia. The precipitated quinia is thus obtained so far exempt from foreign matters, that it may be immediately converted into the sulphate without the necessity of using animal charcoal. From the precipitate by soda, M. Rabourdin obtains the quinia white and pure by treating it with a quantity of dilute muriatic acid insufficient to dissolve the whole of the alkaloid, whereby impurities are left behind, then filtering, and precipitating by ammonia. The same end is accomplished in the Br. process by the use of sulphuric acid. The residue of the precipitate may be reserved for future operations.

Pelletier proposed to substitute oil of turpentine for alcohol in the ordinary process for procuring sulphate of quinia. The impure quinia, precipitated by lime from the acidulous decoctions, after being washed, pressed, and dried, is digested with the oil, which dissolves the quinia. The solution thus obtained is agitated with water acidulated with sulphuric acid, by which the sulphate of quinia is formed. The oil separating, rises to the top, and is removed for future use; and the watery solution of the salt is evaporated, and treated as in the original process. A disadvantage, however, of this method is said to be, that the oil does not completely exhaust the precipitate of its quinia.

A similar process has been employed in England, *fusel oil* or *benzole* being substituted for oil of turpentine. In this instance, however, the new solvent is added to the impure quinia, without separation from the acidulated decoction from which it was precipitated by lime. The mixture being well agitated, the fusel oil or benzole dissolves the alkaloids, and, rising to the surface of the

* Mr. Weightman, of the firm of Powers & Weightman, manufacturing chemists of this city, informs us that the following modification of the above process has been found practically advantageous in their laboratory. The tincture, obtained by acting with alcohol on the impure precipitated quinia, is neutralized with sulphuric acid in the distilling vessel; and the alcohol is then distilled off, leaving a viscid mass of impure sulphate, which is drawn off, and crystallizes on cooling. The mass thus obtained, having been expressed, is dissolved in boiling water, to which purified animal charcoal has been added. The solution is filtered while hot, and then allowed to cool and crystallize. Another solution and crystallization are required to get the sulphate of quinia quite pure and white.—*Note to the tenth edition.*

liquid, is drawn off by a syphon. The solution thus drawn off is treated as above with water acidulated with sulphuric acid, and the process is completed in the same manner. (See *Pharm. Journ.*, xiv. 29, 92, and 139.)

According to the French Codex, 1000 parts of yellow bark ought to yield from 29 to 30 parts of sulphate of quinia, when treated by the process first described. Messrs. Powers & Weightman, who are probably among the largest manufacturers of sulphate of quinia in the world, inform us that they have usually obtained from 2·5 to 3 per cent. as an average product.

Sulphate of quinia may be obtained from other varieties of Peruvian bark by the above processes; and from some in considerable quantity; but most of them yield a much larger proportion of sulphate of cinchonia than the Calisaya; and this, being much more soluble than the sulphate of quinia, will remain dissolved in the residuary liquor after the crystallization of the latter. To obtain the *cinchonia* separate, the following method, originally suggested by Pelletier and Caventou, may be employed. Magnesia, lime, or a solution of potassa is added to the mother-waters in excess.* The cinchonia is precipitated, together with a portion of quinia which has remained in the solution, and with the excess of magnesia or lime, if one of these earths has been employed. The precipitate is collected on a filter, washed with hot water, then dried, and treated with boiling alcohol, which dissolves the organic alkalies. The alcoholic solution is filtered while hot, and the residue afterwards treated in the same manner with successive portions of alcohol, till quite exhausted. The solutions, having been mixed, are concentrated by the distillation of the alcohol, and allowed to cool, when they deposit cinchonia in the crystalline state. Successive evaporations and refrigerations afford new crops of crystals, and the process should be continued till no more can be obtained. The cinchonia thus procured, if impure, should be reconverted into a sulphate and treated as before, animal charcoal being employed to free it from colour. The quinia remaining in the mother-liquors, as it will not crystallize from alcohol, may be obtained by evaporation to dryness. To obtain the *sulphate of cinchonia*, mix the alkaloid with a small quantity of water, heat the mixture, and add gradually dilute sulphuric acid sufficient to saturate it; then boil with animal charcoal previously washed with muriatic acid, and filter the liquid while hot. Upon cooling it will deposit crystals of the sulphate, and, by repeated evaporation and crystallization, will yield all the salt which it holds in solution.†

* Soda is a better precipitant, as it is probably incapable of dissolving any of the alkaloid when employed in excess. In the U. S. formula for procuring sulphate of cinchonia from the mother-waters advantage has been taken of this fact. Hence the process differs from the one given in the text, both in using soda as the precipitant, and in forming the sulphate immediately from the precipitate, which is sufficiently pure for this treatment in consequence of the use of soda, instead of first separating the alkaloid by means of alcohol, and afterwards combining it with sulphuric acid. (See *Cinchoniæ Sulphas*, page 1046.) We retain the account of Pelletier and Caventou's process in the text, in order that the reader may have an opportunity of comparing them.

† A new mode of extracting quinia and other active vegetable principles has been proposed, which, if found as successful on trial as it is said to have been in the hands of its proposer, promises to supersede many of the processes now in use. From the experiments of M. Lebourdais, it would appear that purified animal charcoal has the property of abstracting from many vegetable products not only their colouring, but their sapid principles also, and afterwards of yielding the active matter uncombined to boiling alcohol, from which it is obtained by evaporation. M. Lebourdais deprived Peruvian bark of all its soluble principles by repeated maceration in alcohol of 0·923, filtered the resulting liquors, removed the alcohol by distillation, and mixed the liquid residue with a decoction made by boiling the same bark twice in distilled water. Acetate of lead was added to precipitate the resinous matter; and the liquor, having been filtered, was made to pass slowly through purified animal charcoal, by which it was deprived of colour and taste. The charcoal was then washed, dried, and treated with alcohol of 0·848. The alcoholic solution thus obtained, upon being evaporated, yielded the quinia perfectly pure. (*Am. Journ. of*

When barks containing the newly discovered alkaloids *cinchonidia* and *quinidia* (see *page* 290) are used, as their sulphates are much more soluble than that of quinia, it follows that, in the mother-waters left after the crystallization of sulphate of quinia, there will be found a portion of sulphate of cinchonidia or

Pharm., xxi. 92, from *Ann. de Chim. et de Phys.*) A chemist, however, who has tried this process, informs us that he has not found it to answer well in practice.

Mr. Clark proposes to prepare quinia by means of the fatty acids as follows. Having exhausted the bark as usual by acidulated water, he treats the solution with an alkaline carbonate so long as a precipitate is produced, then adds a little stearic acid, and boils the whole. The fatty acid melts, floats on the surface, and there attracts the quinia and cinchonia, forming a kind of insoluble soap, while the precipitate and liquid become black. On cooling, the fatty matter coagulates, and, on being withdrawn and boiled in water so long as this remains limpid, and then treated with boiling acidulated water, yields the quinia and cinchonia to the acid. The hot solution, being neutralized by an alkali, deposits a brown matter, which is to be separated by filtration, and on cooling yields the sulphate of the two alkaloids in a crystalline state. The quinia and cinchonia can then be separated in the ordinary mode. (See *Journ. de Pharm*, Dec. 1861, p. 463.)

We have been told that considerable quantities of a preparation have been imported from South America, consisting of a mixture of the alkaloids of bark in an impure state, obtained by forming acidulated decoctions of bark, precipitating with lime, treating the precipitate with alcohol, and evaporating the alcoholic solution. From this material the sulphates of quinia and cinchonia have been prepared on a large scale. It has sometimes yielded 25 per cent. of quinia converted into sulphate, and more than an equal quantity of cinchonia. — *Note to the eighth and tenth editions.*

Quinoidine. Precipitated Extract of Bark. Amorphous Quinia. Cinchonicia and Quinicia of Pasteur. Upon the evaporation of the mother-liquor left after the crystallization of sulphate of quinia in the preparation of that salt, a dark-coloured substance is obtained, having the appearance of an extract. This was habitually employed by the late Dr. Emlen and one of the authors of this work, so early as about the year 1824, in the cure of intermittent fever, in which it proved equally effectual with the pure sulphate, though only about half as strong. It was adopted in the edition of the U. S. Pharmacopœia for 1833, under the name of "*impure sulphate of quinia*," but was abandoned in the edition of 1840, on account of the difficulty of ascertaining its purity. Sertürner supposed that he had discovered a new alkaline principle in this product: but his conclusions were invalidated by the experiments of MM. Henry and Delondre, which went to prove that the alkaline matter contained in it consisted of quinia and cinchonia, obscured by admixture with a yellowish substance that interfered with their crystallization. Nevertheless, under the name of *quinoidine* or *chinoidine*, given to the supposed new alkaloid by Sertürner, there has been long employed in Europe a substance precipitated from the mother-liquor of sulphate of quinia by means of an alkaline carbonate, having a yellowish-white or brownish colour, and, when moderately heated, agglutinating into a mass of a resinous appearance. This substance was found by Dr. F. L. Winckler to contain an uncrystallizable alkaline principle, having the same combining weight as quinia, and differing from that alkaloid only in the want of the property of crystallization, and in forming uncrystallizable salts with the acids. (*Pharm. Cent. Blatt.* May, 1847, p. 310.) Liebig afterwards proved it to be identical in composition with ordinary quinia, to which he considered it as bearing the same relation that uncrystallizable sugar bears to the crystallizable. Pasteur has found that ordinary quinoidine, or amorphous quinia, consists of two alkaloids, derivatives from quinia and cinchonia, with which they are respectively isomeric, though differing in being uncrystallizable, and named, in view of their origin, *quinicia* and *cinchonicia*. The pure amorphous quinia of Liebig is the former of these alkaloids. (See *page* 291.) This substance has been found equally effectual with quinia in the cure of intermittents. In an economical point of view, it is highly important that it should be employed. It is sometimes sold under the name of *precipitated extract of bark*, and there can be little doubt that it enters into other preparations, which, under the name of extract of bark, have been put forth as peculiarly valuable for the cure of intermittents. It must not be confounded with the substance obtained by evaporating the mother-liquors, which is of uncertain composition and strength. The chief objection to it is its liability to adulteration. The *amorphous quinia*, as Liebig calls it, is entirely soluble in dilute sulphuric acid and in alcohol; and, if its solution in a dilute acid yield upon the addition of ammonia exactly as much precipitate as there was of the original substance dissolved, it may be considered pure. (See *Am. Journ. of Pharm.*, xviii. 181.) We have been informed that, in an extensive chemical manufacturing establishment in Philadelphia, since the introduction of steam heat, the loss by quinoidine in the preparation of sulphate of quinia has much diminished, showing the agency of heat in converting the crystallizable into the uncrystallizable salt.

quinidia, or of both. In fact, there is generally, under these circumstances, more or less of the sulphates of the four alkaloids, quinia, cinchonia, quinidia, and cinchonidia, all of which are contained in many barks; and, besides these, a portion of amorphous alkaloid, incapable of crystallization, probably resulting, in part at least, from the heat employed in the process. These may in a great degree be separated through their different solubilities in water. Sulphate of quinia being least soluble will first crystallize, afterwards the salt of cinchonidia or quinidia, and finally that of cinchonia, which is the most soluble of the four; while the uncrystallizable salt will remain in solution, and may be obtained in the amorphous state by evaporation to dryness.

Properties. Sulphate of quinia is in fine silky, slightly flexible, needle-shaped crystals, interlaced among one another, or grouped in small star-like tufts. Its taste is intensely bitter, resembling that of the yellow bark. It effloresces slightly on exposure to the air, and, at a moderate heat, loses its crystalline form in consequence of the escape of its water of crystallization. At the temperature of 212° it becomes luminous, especially when rubbed. At about 240° it melts, assuming the appearance of wax. It is very slightly soluble in cold water, requiring, according to M. Baup, 740 parts at 54° F. for solution; while at the boiling point it is dissolved in 30 parts of water, which deposits it upon cooling.* Its cold solution is opalescent. It is soluble in about 60 parts of cold alcohol of 0·835, but only to a very small extent in ether. The diluted acids, even tartaric and oxalic acids in excess, dissolve it with great facility. With an additional equivalent of sulphuric acid it forms another sulphate, which is more soluble in water than the officinal salt, and crystallizes from its solution with much greater difficulty. This is now considered by many as strictly neutral, and therefore entitled to the name of sulphate of quinia; while the officinal salt is thought to contain two equivalents of base to one of acid, and is therefore a *subsulphate* or *disulphate of quinia*. The latter name was adopted by the London College, and is much used by chemical writers. In the U. S., Dublin, and Edinburgh Pharmacopœias, as well as in the French Codex, the name of sulphate of quinia, originally given to the officinal salt, under the impression that it was neutral, was retained; and it has been assumed in the new British Pharmacopœia. Hence has arisen a confusion of nomenclature, which must be embarrassing to the student. Our own impressions are in favour of the higher number of the equivalent of quinia, and consequently of the view which considers the officinal name of sulphate of quinia as properly representing the composition of the salt. According to M. Baup, the higher sulphate, formerly called *supersulphate*, and still considered by some chemists as the *bisulphate*, is soluble in 11 parts of water at 54° F., and in its own water of crystallization at a boiling point. It is very soluble in diluted, and somewhat less so in absolute alcohol. It may be obtained by adding to a boiling concentrated solution of the ordinary sulphate, as much sulphuric acid as already exists in the salt, and then evaporating the solution.

Composition. The officinal sulphate of quinia, the disulphate of most chemists, is the only one used in medicine, and to this we have allusion in the present work, whenever sulphate of quinia is mentioned without any distinguishing epithet. In the crystalline form it consists, if regarded as neutral, of one eq. of quinia 324, one of sulphuric acid 40, and eight eqs. of water 72 = 436; but if considered, in accordance with Liebig's views, as a subsulphate or disulphate, of two eqs. of quinia (each 162), one of sulphuric acid, and eight of water; the whole eq. of the salt being, of course, the same in either case. On exposure to the air, or to a heat of 212°, it effloresces, losing one-half of its water of crystal

* M. Calloud has ascertained that the solubility of sulphate of quinia is much affected by certain salts. While it is increased by muriate of ammonia, nitrate of potassa, and chloride of sodium, it is diminished by the sulphates of soda and magnesia. Sulphate of quinia is decomposed wholly or in part by bicarbonate and phosphate of soda. (*Pharm. Journ.*, June, 1860, p. 609.)

lization; and at 240° it loses one-half of the remainder, retaining two eqs. or about 4 per cent. of water, of which it cannot be deprived without decomposition. (*Phillips.*)*

* *Iodide of Sulphate of Quinia, &c.* This remarkable compound of officinal sulphate of quinia was discovered by Dr. Wm. Bird Herapath, of Bristol, England, who also investigated its singular optical properties. If to a solution of sulphate of quinia in a mixture of acetic acid and diluted alcohol, tincture of iodine be added by drops, and the mixture kept at 130° F. until perfect solution takes place, upon the cooling of the liquid, crystals will gradually form, which Dr. Herapath has found to consist of iodine, quinia, and sulphuric acid, probably combined in the state of *sulphate of iodo-quinia*. To obtain fine crystals various precautions are necessary, for which the reader is referred to the paper of Dr. Herapath. The crystals are of a brilliant emerald-green when viewed by reflected light, but almost colourless by transmitted light, and present a curious play of colours under varying circumstances of position. Their shape is very diversified, but traceable to the rhombic prism. They are dissolved by heated acetic acid and heated alcohol, and deposited on cooling. Their most remarkable property is that of polarizing light, in which they are equal if not superior to the tourmaline, for which they may be substituted with advantage in experiments in this branch of optics. (*Pharm. Journ.*, xi. 448 and 449, and xiii. 378. See also *Am. Journ. of Pharm.*, xxvi. 18.) From subsequent experiments of Dr. Herapath, it appears that the other cinchona alkaloids form similar salts with iodine; so that crystals may be obtained of the *sulphates of iodo-quinidia, iodo-cinchonia*, and *iodo-cinchonidia*, as well as of iodo-quinia. But the reader will note that the nomenclature of the alkaloids adopted by Dr. Herapath differs from that of Pasteur, and unfortunately we think, as that of Pasteur is based on the analogies of the alkaloids. The quinia and cinchonia are the same with both, but the quinidia of Pasteur is the cinchonidia of Herapath, and vice versa. In the following observations the nomenclature of Dr. Herapath is used, in justice to that writer. It appears that, of these different compounds, there is a close analogy in crystalline forms between the iodo-quinia and iodo-cinchonidia salts on the one hand, and the iodo-cinchonia and iodo-quinidia salts on the other, while between the two twin sets there is a decided difference; so that there is no difficulty in deciding whether a quinia salt contains quinidia or cinchonia, or a cinchonia salt cinchonidia or quinia, yet it may not be so easy to discriminate between the salts of analogous forms. Nevertheless there are sufficient points of dissimilarity to enable a correct diagnosis to be made. It is not by their chemical characters that these iodo-salts can be discriminated; though the cinchonia and quinidia salts dissolve with greater difficulty than the others in consequence of their greater thickness, and less extent of surface. The crystals of the *cinchonidia* salt (*quinidia*, Pasteur), like those of the sulphate of iodo-quinia, are derived from the rhombic prism, but differ in certain points which we have not space to detail, and in reference to which we must be content to refer to Dr. Herapath's paper. They are distinguishable to the practised eye by their different tint with reflected and transmitted light. But these salts differ greatly from the *iodo-cinchonia* and *iodo-quinidia* (*iodo-cinchonidia*, Pasteur) *sulphates*. The crystals of the latter of these salts are long quadrilateral acicular prisms, of a deep-ruby or garnet-red colour, with bluish-violet or light-purplish reflection tints, or they have the form of thin plates, or long, flat, acicular prisms, which, when thin, transmit a pure yellow, but if thicker, a reddish colour tinged with brown. The analogous *iodo-cinchonia sulphate* is in long, acicular, quadrilateral prisms, of a deep purplish-black colour; and in relation to transmitted light also closely resembles the preceding. All these iodo-salts have double refractive properties. Dr. Herapath gives the following as their composition; 1. *sulphate of iodo-quinia*, $C_{37}H_{33}N_2O_5.I_2+2SO_3HO+5HO=840$; 2. *sulphate of iodo-cinchonidia* (*iodo-quinidia*, Pasteur), $C_{37}H_{33}N_2O_5.I_3+2SO_3HO+5HO=967$; 3. *sulphate of iodo-cinchonia*, $C_{35}H_{19}N_2O_2.I_3+SO_3HO+6HO=757$; 4. *sulphate of iodo-quinidia* (*iodo-cinchonida*, Pasteur), $C_{35}H_{19}N_2O_4.I_2+SO_3HO+5HO=637$. When the acid sulphates of the mixed alkaloids, quinia, quinidia, cinchonia, and cinchonidia, are dissolved in dilute alcohol, and the solution heated to from 80° to 120°, tincture of iodine readily separates the quinia salt; further treatment in the same manner separates the cinchonidia (quinidia, *Pasteur*) salt, more or less mixed with the preceding; still further treatment, the quinidia (*cinchonidia*, Pasteur) salt with its well-marked characters; and the cinchonia salt, being by far the most soluble, is the last to appear, but if in large proportion will be mixed with the quinidia (cinchonidia) salt. Cinchonidia (quinidia) may thus be readily detected in cinchonia, which might otherwise be considered pure. In like manner a mixture of quinidia (cinchonidia) with quinia is easily made evident. (See *Am. Journ. of Pharm.*, May, 1858, p. 246, from *Pharm. Journ.*, March, 1858.)

The rotating powers of the cinchona salts in reference to polarized light also afford means of distinguishing them, to those who may possess the requisite apparatus. Allusion has been made to these properties under the several alkaloids in the first part of the work. It may be proper to say here that quinia and cinchonidia (*Pasteur*) are strongly lævogy-

Incompatibles and Tests. Sulphate of quinia is decomposed by the alkalies, their carbonates, and the alkaline earths. In solution, it affords white precipitates with potassa, soda, and ammonia, which are partly soluble in an excess of alkali. It is also precipitated by astringent infusions, the tannic acid of which forms a white insoluble compound with quinia. The soluble salts of lead and of baryta occasion precipitates; and that produced by the salts of baryta is insoluble in the acids. The soluble salts of oxalic, tartaric, and gallic acids occasion more or less precipitation with solution of sulphate of quinia without excess of acid; and Mr. J. M. Maisch has ascertained the same to be true of the acetates. (*Am. Journ. of Pharm.*, xxvii. 97.) A freshly prepared solution of chlorine, added to a solution of sulphate of quinia, and followed by the addition of water of ammonia, occasions an emerald-green colour, and, in certain proportions, the deposition of a green precipitate. If, previously to the use of ammonia, a concentrated solution of ferrocyanide of potassium be added, a dark-red colour is produced, which persists for several hours, but ultimately passes into green. This does not take place with cinchonia. Sulphate of quinia gives a reddish-brown precipitate with iodine dissolved in a solution of iodide of potassium.

Adulterations. Sulphate of quinia has often been adulterated. The effects of adulteration may be produced by the variable quantity of water which sulphate of quinia may contain, without any observable alteration in its sensible properties. MM. Millon and Commaille, having exposed sulphate of quinia to a very moist atmosphere, at the temperature of about 62° F., found it always to increase in weight; so that a specimen of the salt, previously deprived of all its water capable of being separated by heat, had in five days absorbed 28·77 per cent. of water, and another specimen dried after its precipitation simply by draining, and supposed to contain 18 per cent. of water, had in ten days absorbed 14 per cent. more, making its whole percentage of water 32, or about one-third of its weight. (*Journ. de Pharm.*, Nov. 1862, p. 379.) This is an important fact, and will explain, to some extent, the frequently variable effects from apparently the same quantity of the salt. It is easy to detect and to obviate this natural sophistication by exposing a suspected specimen to a heat of 212°. The loss of weight will indicate the quantity of water, not essential to the salt. Sulphate of lime, and other alkaline or earthy salts, gum, sugar, mannite, starch, stearin or margarin, caffein, salicin, phloridzin, and the sulphates of cinchonia and other cinchona alkaloids, are among the substances which are said to have been fraudulently added. By attending to the degree of solubility of the sulphate in different menstrua, and to its chemical relations with other substances already described, there can be little difficulty in detecting these adulterations. The presence of any mineral substance, not readily volatilizable, may be at once ascertained by exposing the salt to a red heat, which will completely dissipate the sulphate of quinia, leaving the mineral behind. A volatile ammoniacal salt may

rate, while cinchonia and quinidia (*Pasteur*) are strongly dextrogyrate, and quinicia and cinchonicia slightly dextrogyrate.

We may here, however, refer to another test, requiring instrumental aid, offered by Mr. W. Walter Stoddart. If a drop of a solution of sulphocyanide of potassium be added to a saturated and neutral solution of a suspected specimen of sulphate of quinia, and the mixture be observed, by means of the microscope, if cinchonia or quinidia (cinchonidia, *Pasteur*) be present, characteristic crystals of sulphocyanide of these alkaloids will be noticed, wholly distinct in shape from those of sulphocyanide of quinia formed at the same time. (*Pharm. Journ.*, Oct. 1864, p. 155, and *Am. Journ. of Pharm.*, Jan. 1865, p. 41.)

Still another newly discovered mode of distinguishing between quinia and cinchonia, suggested by M. Palm is one based on the influence of polysulphuret of potassium on those alkaloids. If a solution of this reagent be added to a boiling solution of a salt of quinia, this, however small may be its proportion, will be thrown down as a red, viscid mass, which hardens upon cooling, and assumes a resinous appearance; whereas cinchonia is separated as a white powder containing sulphur. The polysulphuret is prepared by boiling a solution of potassa with an excess of sulphur. (*Journ. de Pharm.*, Mai, 1864, p. 459.) —*Notes to the eleventh and twelfth editions.*

be detected by the smell of ammonia emitted upon the addition of potassa. The absence of organic substances may be inferred, if pure cold concentrated sulphuric acid forms a colourless solution. Gum and starch are left behind by alcohol, and fatty matters by water acidulated with sulphuric acid. Sugar and mannite cause a solution of the salt in acidulated water to have a sweet taste, after the precipitation of the quinia by an alkaline carbonate. Salicin imparts the property of becoming red upon the contact of sulphuric acid; but, according to Pelletier, this change of colour does not take place, unless the proportion of salicin exceeds one-tenth. If only in this proportion, the salicin must be isolated. To 1 part of the suspected salt, 6 parts of concentrated sulphuric acid may be added, and to the brown liquid which results, 125 parts of water. The salicin is thus separated, and may be obtained by filtration, in the form of a bitter, white powder, becoming bright red with sulphuric acid. (See *Am. Journ. of Pharm.*, xvii. 156.)* Caffein alters the solubility of the medicine in different menstrua. According to M. Calvert, a saturated solution of sulphate of quinia in cold water gives, with a solution of chloride of lime, a precipitate soluble in an excess of the latter; while a solution of sulphate of cinchonia of the same strength, treated in the same manner, gives a precipitate which is insoluble in a great excess of the reagent. The same effect is produced with lime water, and solution of ammonia; and solution of chloride of calcium, while it furnishes a precipitate with a solution of sulphate of cinchonia, yields none with a solution of sulphate of quinia. (*Journ. de Pharm.*, 3e *sér.*, ii. 394.)† The Edinburgh

* For a method of detecting the presence of salicin by the saliretin produced, and of determining the proportion of salicin, by means of the glucose resulting, when the salicin is decomposed by muriatic acid, see a communication by M. Bourlier in the *Journal de Pharmacie* (Juillet, 1859, p. 34).

† Liebig's test of the presence of cinchonia is perhaps the simplest. Rub together fifteen grains of the suspected salt and two ounces of solution of ammonia, put the mixture into a flask, add two ounces of ether, and shake frequently. The quinia liberated by the ammonia is dissolved by the ether, while any cinchona that may be present remains undissolved, floating between the ethereal solution above and the ammoniacal beneath. But M. O. Henry has shown that cinchonia is slightly soluble in ammonia, so that a small portion might escape detection. It has, therefore, been proposed to modify the test by heating the mixture of the suspected salt and ammonia, so as almost entirely to drive off the excess of this alkali, and then to add the ether. If the liquid now remain quite transparent, without any turbid layer between the upper and lower stratum, it may be inferred that no cinchonia is present. For papers on this subject, see *Journ. de Pharm.* (3e *sér.*, xiii. 102, xvi. 327, and xxi. 284), and *Am. Journ. of Pharm.* (xx. 231, and xxiv. 166).

The precise quantities originally proposed in Liebig's test were one gramme of sulphate of quinia, ten grammes of ether, and two grammes of caustic ammonia. But M. Roger has proved that, with these proportions, in order that the test may succeed, it is necessary to use ether containing alcohol, which is the case with commercial ether. Of pure ether 25 grammes would be requisite for the perfect solution of the quinia from a gramme of the sulphate, while 10 grammes of ether containing but two per cent. of alcohol will produce the same effect. In these proportions the presence of quinidia as well as of cinchonia would be detected. (Roger, *Journ. de Pharm.*, Mars, 1862, p. 204.) For a method of detecting the presence of *quinidia* in sulphate of quinia, the reader is referred to a note in the first part of this work, *page* 296.

For an elaborate account by Dr. G. Kerner of the cinchona alkaloids, of which he believes that there are several not yet fully determined, and of the method of testing commercial sulphate of quinia for the other alkaloids with which it is apt to be contaminated, we must be content with referring to the paper itself, which appeared in the *Zeitschrift für Analytische Chemie*, but a translation of which will be found in the *Pharm. Journ.* for July, 1862, and in the *Am. Journ. of Pharm.* (Sept. 1862, p. 417). Perhaps the most important practical result of these investigations is the suggestion of a new test by which the alkaloids may be distinguished; their solubilities, namely, in water of ammonia of given strength, which, according to Dr. Kerner, are more fixed and reliable than their solubilities respectively in water, or other ordinary solvent. The mode of application is by taking a certain quantity of the sulphate of the alkaloid dissolved in a certain quantity of water, and then adding the water of ammonia gradually until the alkaloid precipitated is redissolved; and the quantity of the ammoniacal liquid necessary to produce this effect indicates inversely

College gave the following mode of testing the purity of sulphate of quinia. "A solution of ten grains in a fluidounce of distilled water and two or three drops of sulphuric acid, if decomposed by a solution of half an ounce of carbonate of soda in two waters [twice its weight of water], and heated till the precipitate shrinks and fuses, yields on cooling a solid mass, which when dry weighs 7·4 grains, and in powder dissolves entirely in solution of oxalic acid." According to the London College, "100 grains dissolved in diluted hydrochloric acid, yield, on the addition of chloride of barium, 26·6 grains of sulphate of baryta, dried at a red heat." Though sulphate of quinia, as prepared for use, frequently contains a portion of one or more of the recently discovered cinchona alkaloids, the salt is probably not less efficacious on that account; as these alkaloids have been shown to possess identical therapeutical properties with those of quinia, and to be little inferior in strength, if at all, in relation to most of them.

Medical Properties and Uses. Sulphate of quinia produces upon the system, so far as we are enabled to judge by observation, the same effects as Peruvian bark, without being so apt to nauseate and oppress the stomach. (See *Cinchona.*) Its effects upon the brain are even more striking than those of cinchona, probably because it is given in larger proportional doses. Even in ordinary doses, it often produces considerable cerebral disturbance, evinced by a feeling of tightness or distension in the head, ringing, buzzing, or roaring in the ears, hardness of hearing, &c. Some individuals are more liable to these effects than others, and in some even small doses produce them. A certain degree of this observable action on the brain is rather desirable than otherwise, as an evidence that the medicine is affecting the system. In very large quantities, as from a scruple to a drachm or more, besides the phenomena mentioned, it has been observed to occasion severe headache, vertigo, deafness, diminution or loss of sight, dilated and immovable pupil, loss of speech, general tremblings, intoxication or delirium, coma, and great prostration. In some instances the pulse has been remarkably diminished in frequency, down to fifty or even less in the minute. In an instance recorded by Giacomini, in which a man took by mistake about three drachms, the patient became insensible, and some hours afterwards was found by the physician in a state of general prostration, from which he recovered under the use of laudanum and aromatic waters. (*Ann. de Thérap.*, A. D. 1843, p. 176.) Besides its effects on the brain, sulphate of quinia sometimes occasions great gastric and intestinal irritation, marked by oppression of stomach, nausea, abdominal pains, vomiting, and purging. In general these effects of excessive doses gradually pass off, although partial deafness often continues for several days, and sometimes much longer. It is even said that permanent deafness has resulted. Though sulphate of quinia has been proved by the experiments of Dr. Baldwin, of Montgomery, Alabama, to be fatal to dogs, if prevented from vomiting by a ligature round the œsophagus, in quantities varying from fifteen or twenty grains to two drachms, with the symptoms of narcotic poisoning; yet we have seen no well authenticated case of death from its direct action on the perfectly healthy human subject. Given largely in disease, it has repeatedly caused fatal results, not so much however by its peculiar action, as by co-operating with the disease in establishing intense local irritation or inflammation, especially in the brain. Though capable, therefore, of doing mischief if improperly used, sulphate of quinia can scarcely be ranked among the poisons.

From its occasional effect in diminishing the frequency of the pulse and the general strength, it has been supposed to be essentially sedative in large doses. Such an opinion, unless well founded, might lead to hazardous practice. The

the solubility of the alkaloid. Quinidia requires from 10 to 11 times more of the menstruum liquid than quinia, cinchonidia from 12 to 13 times more; while cinchonia is not dissolved by a much larger proportion than is required by either of the others, and though, when mixed in very small proportion with quinia it is dissolved at first, yet it afterwards separates on standing.—*Note to the twelfth edition.*

probability is that the apparently sedative effect upon the circulation arises from an overwhelming stimulant influence upon the cerebral centres, whereby the system is deprived of the support of these centres, and the heart's action is depressed with other organic functions. Similar effects may be obtained from excessive doses of most of the cerebral stimulants. Examination of the brain in the lower animals, after death from quinia, has shown great congestion of that organ and its membranes, and even meningitis. (See *Am. Journ. of Med. Sci.*, xix. 197.) In the present state of our knowledge, therefore, it is safest to consider sulphate of quinia as a direct and powerful stimulant to the brain. It probably operates through the circulation, as there is no doubt that it is absorbed, the alkaloid having been found unchanged in the urine.

Sulphate of quinia may be substituted for cinchona in all diseases to which the latter is applicable; and, in the treatment of intermittents, has almost entirely superseded the bark. It has the advantage over that remedy, not only that it is more easily administered in large doses, and more readily retained by the stomach, but that, in cases which require an impression to be made through the rectum or the skin, it is much more effectual; because, from the smallness of its bulk, it is more readily retained in the former case, and more speedily absorbed in the latter. Still we cannot be certain that there are not other active principles in bark besides the alkaloids, which are closely analogous in their effects, nor that the mode of combination in which these principles exist may not in some measure modify their therapeutic action. Until this question is solved, we may resort to the bark if the sulphate of quinia should not answer the ends in view; and instances have occurred, under our own notice, in which it has proved successful in intermittents after the salt had failed.

Sulphate of quinia may be given in pill or solution, or suspended in water by the intervention of syrup and mucilage. The form of pill is usually preferred. (See *Pilulæ Quiniæ Sulphatis.*) The solution may be readily effected by the addition of a little acid of almost any kind to the water. Eight grains of the sulphate will dissolve in a fluidounce of water, acidulated with about twelve minims of the diluted sulphuric acid, or aromatic sulphuric acid of the Pharmacopœias; and this is the most eligible mode of exhibiting the medicine in the liquid form. The addition of a small proportion of sulphate of morphia or of laudanum will often be found advantageous, when the stomach is disposed to be sickened, or the bowels to be disturbed by the quinia. Mr. J. S. Blockey ascertained that glycerin will, if gently heated, dissolve eight grains of the sulphate in each fluidrachm, and may therefore be conveniently used as a vehicle. (*Lond. Chemist*, Sept. 1857.) Dr. R. H. Thomas, of Baltimore, found that one part of tannic acid will deprive five parts of sulphate of quinia of bitterness, without impairing its medicinal efficacy. (*Am. Journ. of Med. Sci.*, N. S., xix. 541.) It is obvious that tannate of quinia is thus formed; and as this, though insoluble in water, is readily dissolved in dilute acids, and consequently in the gastric liquor when acid, there can be no doubt that it will generally prove efficacious. It may, however, happen that the stomach may be quite free from acid, and that the operation of this salt may prove less certain than that of the sulphate; and such is asserted to have been the case in some instances; but a little lemonade taken after the medicine would probably obviate the difficulty.

Twelve grains of sulphate of quinia are equivalent to about an ounce of good bark. The dose varies exceedingly, according to the circumstances of the patient, and the object to be accomplished. As a tonic simply, a grain may be given three or four times a day, or more frequently in acute cases. In intermittents, from twelve to twenty-four grains should be given between the paroxysms, divided into smaller or larger doses according to the condition of the stomach, or the length of the intermission. From one to four grains may be given at once, and some even advise the whole amount. In malignant intermittents and remit-

tents, the quantity may be increased to thirty grains or even a drachm between the paroxysms. M. Maillot gave one hundred and twenty-eight grains, in the course of a few hours, in a case of malignant fever occurring in Northern Africa, with the happiest results. The caution, however, is necessary, not to employ this heroic practice against easily conquerable diseases. Very large doses of the sulphate have recently been given in acute rheumatism, and with great asserted success; but the occurrence of at least one fatal case from inflammation of the brain should lead to some hesitation in this employment of the remedy. When the stomach will not retain the medicine, it may be administered with nearly as much efficacy by enema; from six to twelve grains, with two fluidounces of liquid starch, and from twenty to forty drops of laudanum, being injected into the rectum, in ordinary cases, every six hours. Should circumstances render this mode of application impracticable, an equal quantity, diluted with arrow-root or other mild powder, may be sprinkled, at the same intervals, upon a blistered surface denuded of the cuticle. The epigastrium, or the inside of the thighs and arms, would be the proper place for the blister. The sulphate has also been employed by friction in the form of ointment, in cases of malignant intermittent. The ointment should be made by incorporating a saturated alcoholic solution of the salt with lard, and should be applied to the inside of the thighs and arms. It is said that quinia is more readily absorbed when united with a fatty acid. This union may be effected by mixing solutions of soap and of a salt of quinia. The quinia soap is precipitated. Purified oleic acid will dissolve one-tenth of its weight of sulphate of quinia, if aided by a gentle heat; and this solution may be used as a liniment. (See *Am. Journ. of Pharm.*, xxvii. 73.)

Solutions of sulphate of quinia have been advantageously employed as local applications to indolent ulcers, and chronic mucous inflammations. (Wedderburn and Fearn, *New Orleans Med. and Surg. Journ.*, iii. 161 and 341.)

QUINIÆ VALERIANAS. *U. S. Valerianate of Quinia.*

"Take of Valerianic Acid *half a troyounce;* Sulphate of Quinia *two troyounces;* Diluted Sulphuric Acid, Water of Ammonia, Water, each, *a sufficient quantity*. Dissolve the Sulphate of Quinia in a pint of Water, with the aid of Diluted Sulphuric Acid; then add Water of Ammonia in slight excess, and wash the precipitated quinia with water until freed from sulphate of ammonia. Dissolve the Valerianic Acid in five pints of Water, heated to 180°, add the quinia to the solution, and, when it is dissolved, set the whole aside for several days to crystallize. Decant the mother-water from the crystals, dry them on bibulous paper, and keep them in a well-stopped bottle. By evaporating the mother-water at a temperature not exceeding 120°, more crystals may be obtained." *U. S.*

In this process quinia is first obtained by decomposing sulphate of quinia, by means of ammonia, and then combined directly with valerianic acid, to form valerianate of quinia, which crystallizes from the solution when it cools, because much less soluble in cold than in hot water. By the late Dublin formula, which, with the salt itself, has been omitted in the British Pharmacopœia, the valerianate was obtained by double decomposition between muriate of quinia and valerianate of soda, resulting in the production of chloride of sodium, which remained in solution, and valerianate of soda, which crystallized.

Valerianate of quinia is a colourless salt, crystallizing in rhomboidal plates. It has a bitter taste, and the strong, adhesive odour of valerianic acid, which is very repulsive, and quite distinct from that of oil of valerian. It is soluble in 110 parts of cold and 40 parts of boiling water, and is deposited from its warm solution in fine crystals on cooling. It is dissolved by 6 parts of cold, and by an equal weight of boiling alcohol, and is soluble also in ether. In boiling water it melts into oily globules, and undergoes decomposition, with the escape of vale-

rianic acid; and hence the direction in the formula not to exceed 120° in evaporating the mother-water. Even at common temperatures it is probably undergoing a constant, though slow loss of the acid, of which it smells so strongly. Exposed to a dry heat, it melts and gives off white vapours. It may be given in the dose of a grain or two repeated several times a day, in cases of debility attended with nervous disorder. A combination of Peruvian bark and valerian has long been known as peculiarly efficacious in hemicrania. Perhaps the valerianate of quinia may be used advantageously in the same affection. W.

RESINÆ.

Resins.

The *Resinæ* or *Resins* of the U. S. Pharmacopœia constitute a peculiar class of preparations, made by exhausting the substances from which they are obtained by alcohol, and then precipitating the resinous matter from the tincture, by the addition of water, which abstracts the alcohol by its stronger affinity. It is obvious that the resins thus prepared are different substances from the alcoholic extracts, which contain all the ingredients of the medicine which alcohol is able to take from it.

RESINA JALAPÆ. *U. S.* JALAPÆ RESINA. *Br.* *Resin of Jalap.*

"Take of Jalap, in fine powder, *sixteen troyounces;* Alcohol, Water, each, *a sufficient quantity.* Moisten the Jalap with four fluidounces of Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it until four pints have passed, or until the filtered liquid ceases to occasion turbidness when dropped into water. Reduce the tincture to half a pint by distilling off the alcohol, mix the residue with four pints of Water, separate the precipitate formed, wash it thoroughly with Water, and dry it with a gentle heat." *U. S.*

"Take of Jalap, in coarse powder, *eight ounces* [avoirdupois]; Rectified Spirit, Distilled Water, each, *a sufficiency.* Macerate the Jalap with sixteen fluidounces of the Spirit in a covered vessel, at a gentle heat, for twenty-four hours; then transfer to a percolator, and, when the tincture ceases to pass, pour into the percolator successive portions of Spirit until the Jalap is exhausted. Add to the tincture four fluidounces of the Water, and distil off the Spirit by a water bath. Remove the residue while hot to an open dish, and allow it to become cold. Pour off the supernatant fluid from the resin, wash this two or three times with hot water, and dry it on a porcelain plate by a stove or water bath." *Br.*

The two processes probably do not differ very materially in the result; though, if jalap yield anything to alcohol that is insoluble in water besides resin, it will be necessarily found in the British preparation, while that of the U. S. Pharmacopœia consists of resin almost exclusively. The difference arises from the circumstance that, in the Br. process, probably to enable the whole of the alcohol to be saved by distillation, the water for precipitation is added before the spirit is distilled off, while, in the U. S. process, it is not added until so much of the alcohol has been distilled as to leave only enough to hold the extracted matters in solution. It is obvious, therefore, that the resin of the former contains everything insoluble in water that the alcohol had extracted; while that of the latter contains nothing which water was unable to precipitate from the half pint of concentrated tincture. The U. S. resin is probably, therefore, a purer product than the British.

The U. S. resin, though tolerably pure, and quite sufficiently so for practical purposes, is still coloured. To obtain it colourless, if this be desired, the powdered jalap should be mixed, before percolation, with an equal quantity of finely powdered animal charcoal, and, previously to the introduction of this mixture into the percolator, half the quantity of animal charcoal, similarly powdered,

should be packed in the bottom of the instrument. The colouring matter is thus left behind; and the resulting tincture, treated as directed in the process, yields the resin as white as starch.

Resin of jalap consists of two portions, one of which is hard and insoluble in ether, the other is soft and soluble in that menstruum; the former constituting about 70 per cent. It is insoluble in oil of turpentine. (*Squire.*) For an account of its chemical properties the reader is referred to the article on jalap, in *Part I.* It was at one time supposed that the purgative properties of the resin resided chiefly if not exclusively in the hard resin; but experiments by Mr. John C. Long appear to prove that the soft is equally energetic. (*Am. Journ. of Pharm.*, Nov. 1861, p. 489.)

Guaiac, rosin, and other resinous substances are said to be sometimes fraudulently added to the resin of jalap. Guaiac may be detected by the green colour it produces, when a few drops of solution of chloride of soda or of lime are added to an alcoholic solution of the suspected resin. (*Journ. de Pharm., 3e sér.*, x. 357.) According to G. A. Kaiser, jalap resin may be distinguished from all other resins by being gradually dissolved by concentrated sulphuric acid, and depositing, after some hours, a brown soft viscid matter. (*Chem. Gaz.*, Jan. 1845, from *Liebig's Annalen.*) A better test is probably that proposed by A. Buchner. When pure jalap resin is dissolved in an alkaline solution, it is not precipitated by the addition of sulphuric or muriatic acid, having been converted, through the agency of the alkali, into an acid soluble in water. All the adulterating resins yield precipitates under the same circumstances. The resins of scammony and of fusiform jalap act in this respect like the true jalap resin, but are distinguishable by being wholly soluble in ether, which jalap resin is not. (*Neues Repert. für Pharm.*, No. 1, 1854.)

It is now generally believed that the resin of jalap is its sole purgative principle, the gummy extractive being either simply diuretic or wholly inert. Nevertheless, the extract of jalap probably better represents the whole virtues of the root, its specially hydragogue as well as simply purgative property; or at least contains the resin so involved with other ingredients, as in some measure to qualify its irritant and griping properties, and thus favourably modify its cathartic action. To obviate the occasional harshness of the resin, it has been advised to triturate it with loaf-sugar, sulphate of potassa, almond emulsion, or other substance calculated to separate its particles. The dose is from two to five grains. W.

RESINA PODOPHYLLI. *U. S.* PODOPHYLLI RESINA. *Br. Resin of May-apple. Resin of Podophyllum.*

"Take of May-apple, in fine powder, *sixteen troyounces;* Alcohol, Water, each, *a sufficient quantity.* Moisten the May-apple with four fluidounces of Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it until four pints have passed, or until the filtered liquid ceases to occasion turbidness when dropped into water. Reduce the tincture to half a pint by distilling off the alcohol, mix the residue with four pints of Water, separate the precipitate formed, wash it thoroughly with Water, and dry it with a gentle heat." *U. S.*

"Take of Podophyllum, in coarse powder, *one pound* [avoirdupois]; Rectified Spirit, *three pints*, or *a sufficiency;* Distilled Water, Hydrochloric Acid, each, *a sufficiency.* Exhaust the Podophyllum with the Spirit by percolation; place the tincture in a still, and draw off the spirit. Acidulate the Water with one twenty-fourth of its bulk of Hydrochloric Acid, and slowly pour the liquid which remains after the distillation of the tincture into three times its volume of the acidulated water, constantly stirring. Allow the mixture to stand for twenty-four hours to deposit the resin. Wash the resin on a filter with Distilled Water, and dry it on a stove." *Br.*

There is a considerable difference between the preparations resulting from

these two processes The U. S. preparation is obtained simply by precipitating a concentrated tincture of the root by water, and consists mainly of the peculiar resin of podophyllum; the British, by precipitating with water acidulated by muriatic acid, whereby berberina, an alkaloid recently found to exist in podophyllum, is thrown down in the state of an insoluble muriate. As berberina exists in the may-apple, it is so combined as to be soluble both in alcohol and water, and is therefore contained in the concentrated tincture. But, having the remarkable property of forming an insoluble salt with muriatic acid, it is thrown down along with the resin; so that the resulting preparation is a mixture of the proper resin of podophyllum with this salt. Hence the British resin is of a yellow colour, given to it by the muriate of berberina, while the U. S. resin is drab-coloured. It follows that the British resin is a more exact representation of the virtues of the root than ours, while the latter is perhaps preferable simply as a purgative. Mr. Maisch has found some berberina in the resin precipitated by water from the concentrated tincture, which is removed by washing with hot water, and probably also by the thorough washing with cold water directed by the Pharmacopœia. (*Am. Journ. of Pharm.*, July, 1863, p. 303.) The percentage of resin obtained from the root, as given by different operators, varies from 3·12 to 5·25 per cent.

Resin of podophyllum has a light-brown colour, an acrid bitter taste, and a slight odour of the root. It consists of two resins, one soluble both in ether and alcohol, the other in alcohol only. The resin extracted by ether constitutes, according to Mr. John W. Cadbury, 75 per cent. of the whole (*Am. Journ. of Pharm.*, July, 1858, p. 301), according to Mr. Harvey Allen, 80 per cent. (*Ibid.*, May, 1859, p. 206). The officinal resin is soluble in alkaline solutions, from which it is precipitated by acids, in this respect differing strikingly from the resins of jalap and scammony. It is insoluble in oil of turpentine. The name of *podophyllin*, given to it by the practitioners calling themselves eclectics, who have long been in the habit of using this resin, is inappropriate, and should be abandoned.

Resin of podophyllum is a powerful cathartic, occasionally producing some griping and nausea, but capable of being favourably modified by combination, and of being very usefully employed in connection with other cathartics, to give them increased energy. It is supposed by some to be specially cholagogue; but though, like all other active cathartics, it may occasionally produce bilious stools by emptying the gall-bladder, there is no sufficient proof that it increases especially the secretory function of the liver. There has been much difference of opinion as to the relative activity of the two resins composing it, some maintaining that both are active, others that the activity resides mainly, if not exclusively, in the resin soluble in ether. It is difficult to resist the evidence of the experiments of Mr. Cadbury, who states in the paper above referred to that, while half a grain of the ethereal resin acted energetically, and a cathartic effect was produced by even one-fourth of a grain, the portion insoluble in that menstruum was given in the dose of one grain without any effect whatever. The dose of the officinal resin is from one-fourth of a grain to a grain. It should generally be given in combination. A small proportion of extract of belladonna or hyoscyamus is said much to mitigate its irritant action. W.

RESINA SCAMMONII. *U. S.* Scammoniæ Resina. *Br. Resin of Scammony.*

"Take of Scammony, in fine powder, *six troyounces;* Alcohol, Water, each, *a sufficient quantity.* Digest the Scammony with successive portions of boiling Alcohol until exhausted. Mix the tinctures, and reduce the mixture to a syrupy consistence by distilling off the alcohol. Then add the residue to a pint of Water, separate the precipitate formed, wash it thoroughly with Water, and dry it with a gentle heat." *U. S.*

"Take of Scammony Root, in coarse powder, *eight ounces* [avoirdupois]; Rectified Spirit, Distilled Water, each, *a sufficiency*. Macerate the Scammony Root with sixteen fluidounces of the Spirit in a covered vessel, at a gentle heat, for twenty-four hours; then transfer to a percolator, and, when the tincture ceases to pass, pour into the percolator successive portions of Spirit until the root is exhausted. Add to the tincture four fluidounces of the Water, and distil off the Spirit by a water bath. Remove the residue while hot to an open dish, and allow it to become cold. Pour off the supernatant fluid from the resin, wash this two or three times with hot water, and dry it on a porcelain plate by a stove or water bath." *Br.*

The U. S. and British resins, though procured, the former from the gum-resin, the latter from the root of the plant, are nearly identical in their effects. The advantage of the preparation is that the resin is obtained free from the inert matters with which it is so often associated in the scammony of commerce. When pure virgin scammony can be procured any preparation is unnecessary. Obtained according to the U. S. process, the resin is of a dirty greenish-brown colour, with a feeble odour and taste of scammony, and is very soluble in ether, alcohol, and boiling proof spirit. When purified with animal charcoal it has a pale brownish-yellow colour, and is without odour or taste; but retains its purgative property. The Br. resin is in brownish translucent pieces, with a resinous fracture, and of a sweetish, fragrant odour derived from the root, and wholly different from that of scammony.

The resin of scammony is liable to adulteration. Jalap resin may be detected by its partial insolubility in rectified ether, which dissolves that of scammony in all proportions. Sulphuric acid is the best test of common rosin or colophony, producing instantaneously with this substance an intense red colour; while in the resin of scammony it causes no immediate change. For the tests of guaiac, the reader is referred to that article in the Materia Medica. (See also *Am. Journ. of Pharm.*, xxiv. 158.) In regard to this sophistication, the Br. Pharmacopœia directs that the tincture shall not render the fresh-cut surface of a potato blue. The presence of other resins, besides those of the Convolvulaceæ, may be known by yielding precipitates when sulphuric acid is added to their alkaline solution; the resin of scammony agreeing with that of jalap in not affording a precipitate under such circumstances. Mr. Ch. Bullock has found this resin, as well as that of jalap and of podophyllum, to be insoluble in benzole, thus enabling any resin soluble in this liquid, which may be employed in their sophistication, to be readily detected. (*Am. Journ. of Pharm.*, March, 1862, p. 114.) When rubbed with unskimmed milk, the resin of scammony forms a uniform emulsion, undistinguishable from rich milk itself. This is an excellent mode of administration. The resin should always be given either rubbed up with some mild powder, or in emulsion. The dose is from four to eight grains.

Off. Prep. Confectio Scammonii, *Br.;* Extractum Colocynthidis Compositum; Mistura Scammonii, *Br.* W.

SANTONINUM.

Santonin.

SANTONINUM. *U. S., Br. Santonin.*

"Take of Santonica, in moderately coarse powder, *forty-eight troyounces;* Lime, recently slaked and in fine powder, *eighteen troyounces;* Animal Charcoal, in fine powder, Diluted Alcohol, Acetic Acid, Alcohol, each, *a sufficient quantity*. Digest the Santonica and Lime with twelve pints of Diluted Alcohol for twenty-four hours, and express. Repeat the digestion and expression twice with the residue, using the same quantity of Diluted Alcohol. Mix the tinctures, and reduce the mixture to eight pints by distilling off the alcohol. Then, having

filtered, and evaporated to one-half, gradually add Acetic Acid until in slight excess, stirring during the addition, and set the whole aside for forty-eight hours. Place the resulting crystalline mass upon a funnel loosely stopped, wash it with water, and dry it. Next, boil the dry residue with ten times its weight of Alcohol, and, having digested the tincture for several hours with Animal Charcoal, filter it while hot, and add sufficient hot Alcohol, through the filter, to wash the Charcoal thoroughly; then set it aside in a dark place to crystallize. Lastly, dry the crystals on bibulous paper in the dark, and keep them in a well-stopped bottle, protected from the light. By evaporating the mother-water, more crystals may be obtained." *U. S.*

"Take of Santonica, bruised, *one pound* [avoirdupois]; Slaked Lime *seven ounces* [avoird.]; Hydrochloric Acid *a sufficiency;* Solution of Ammonia *half a fluidounce;* Rectified Spirit *fourteen fluidounces;* Purified Animal Charcoal *sixty grains;* Distilled Water *a sufficiency.* Boil the Santonica with a gallon [Imperial measure] of the Water and five ounces [avoird.] of the Lime, in a copper or tinned iron vessel, for an hour, strain through a stout cloth, and express strongly. Mix the residue with half a gallon [Imp. meas.] of the Water and the rest of the Lime, boil for half an hour, strain and express as before. Mix the strained liquors, let them settle, decant the fluid from the deposit, and evaporate to the bulk of two pints and a half [Imp. meas.]. To the liquor while hot, add, with diligent stirring, the Hydrochloric Acid until the fluid has become slightly and permanently acid, and set it aside for five days that the precipitate may subside. Remove by skimming any oily matter which floats on the surface, and carefully decant the greater part of the fluid from the precipitate. Collect this on a paper filter, wash it first with cold Distilled Water till the washings pass colourless and nearly free from acid reaction, then with the Solution of Ammonia previously diluted with five fluidounces of the Water, and lastly with cold Distilled Water till the washings pass colourless. Press the filter containing the precipitate between folds of filtering paper, and dry it with a gentle heat. Scrape the dry precipitate from the filter, and mix it with the Animal Charcoal. Pour on them nine ounces of the Rectified Spirit, digest for half an hour, and boil for ten minutes. Filter while hot, wash the charcoal with an ounce of boiling Spirit, and set the filtrate aside for two days in a cool dark place to crystallize. Separate the mother-liquor from the crystals, and concentrate to obtain a further product. Collect the crystals, let them drain, redissolve them in four ounces of boiling Spirit, and let the solution crystallize as before. Lastly, dry the crystals on filtering paper in the dark, and preserve them in a bottle protected from the light." *Br.*

By the U. S. process, which was taken from Wittstein's *Pharmaceutical Chemistry* (page 563), the santonica is first exhausted by digestion with diluted alcohol, in connection with slaked lime; the latter substance being employed to saturate the santonin, and remove colouring matter which might subsequently embarrass the proceedings. The tincture thus obtained, having been reduced by the distillation of the alcohol to little more than an aqueous solution, is filtered and treated with acetic acid, in slight excess, by which the santonin is separated from the lime which holds it in solution, and, being itself insoluble, is gradually deposited in a crystalline state. The remainder of the process is intended simply to obtain the crystals free from colouring matter, and otherwise pure.

The British process, which is that of M. Mialhe somewhat modified (*Pharm. Journ.*, June, 1864, p. 635), spares the expenditure of alcohol in the exhaustion of the santonica, by boiling it originally with water in connection with lime; and differs also from the preceding in precipitating the santonin by muriatic instead of acetic acid. The purification is effected in the same manner, except that solution of ammonia is employed in the washing, probably to remove the last trace of acid. Wormseed of Aleppo yields from 1·2 to 1·4 per cent. of santonin. (*Journ.*

de Pharm., Mars, 1864, p. 241.) It has been intimated to us that the large manufacturers of santonin, abroad, first distil off from the santonica its volatile oil, which has some commercial value in Europe; and that, so far from being injured by the operation, the process for preparing santonin is probably facilitated, in consequence of an affinity of the oil for the santonin, which may render it more difficult to obtain that principle pure.

Properties. Santonin is in colourless crystals, which have the form of flat rhombic prisms. It is inodorous, and at first nearly tasteless, but after a time produces a sense of bitterness. It is fusible by a moderate heat, and assumes the form of a crystalline mass on cooling. At a somewhat higher heat, it rises in dense, white, irritating vapours, and condenses unchanged. The air has no effect upon it, but it becomes yellow on exposure to sunlight. According to M. Sestini, the santonin is changed, through the influence of light, into formic acid, an uncrystallizable substance much more soluble in alcohol and ether than santonin itself, which he calls *photo-santonic acid*, and a red resinous substance. (See *Am. Journ. of Pharm.*, Nov. 1864, p. 527.) It is nearly insoluble in cold water, or in weak acid solutions, but is dissolved by 250 parts of boiling water, by 43 parts of cold and 3 parts of boiling alcohol, and by 75 parts of ether; and its alcoholic and ethereal solutions are extremely bitter. (*U. S.*) It is also freely soluble in chloroform. Though neuter to test paper, it unites with alkaline bases to form crystallizable and soluble salts. In its relations to polarized light, it is very strongly lævogyrate, more so than any other body previously noticed, and retains this property with acids, though losing it entirely when combined with salifiable bases. (Buignet, *Journ. de Pharm.*, Janv. 1862, p. 26.) When exposed to red heat, with access of air, it is entirely dissipated. It consists of carbon, hydrogen, and oxygen; its formula being $C_{30}H_{18}O_6$. In chemical character it appears to be analogous to the stearoptenes, or concrete principles of the volatile oils. Under the influence of sulphuric acid and heat, it is resolved into glucose and a new body, for which the name of *santoniretin* has been proposed, and must therefore rank with the glucosides. (Kosmann, *Journ. de Pharm.*, Août, 1860, p. 81.)

Medical Properties and Uses. The effects of santonin on the system do not appear to have been very precisely determined. Without any very obvious effects on the circulation or digestive organs, it seems to produce some impression of a slightly narcotic character on the brain, and occasionally operates feebly as a diuretic. A singular effect on vision which has often been observed from santonica, is probably owing to the santonin, as similar effects have been produced by that principle. To persons under the influence of santonin, it often happens that all objects appear discoloured, generally yellow, but frequently also green, and sometimes blue. At the same time the urine is tinged of a yellow or green colour; and so rapidly does the santonin pass, that the change of colour in the urine has been observed at the end of 16 minutes. (*Journ. de Pharm.*, Août, 1863, p. 161.) These effects are ascribed to a change in the santonin in the system analogous to that which takes place by its exposure to light; the yellow substance circulating with the blood, and passing out of the circulation with the urine. Santonin has been found to possess the vermifuge properties of santonica, and is probably its exclusive anthelmintic principle; as the volatile oil, to which this property was at one time ascribed, has little or no effect, being probably absorbed from the stomach before it reaches the worms in the bowels, while the santonin, being insoluble, or only becoming so by partial conversion into the santonate of soda when it reaches the bile in the duodenum, passes into the small intestines and poisons the worms. Besides, the volatile oil is poisonous to the system in large doses, while santonin is innocent in any quantity in which it is likely to be administered. (*Edm. Rose, of Berlin.*) A case of poisoning ascribed to santonin was found to be owing to strychnia mixed with it. (*Chem. News*, No. 230, p. 212.) Santonin has also been found advantageous in amaurosis by M. Martin and M.

Guépin, the latter of whom recommends it especially in cases which have succeeded acute choroiditis and iritis, with plastic exudation, after all symptoms of inflammation have ceased. (*Ann. de Thérap.*, 1862, pp. 179, 183.) Santonin may be given in doses of two or three grains twice or three times a day. Some have recommended its salts, but Rose objects to these as being soluble, and therefore not so likely to reach the worm, in consequence of absorption; and, besides, in large doses they are injurious. In amaurosis, M. Guépin uses it in the form of syrup; its solubility being, in this case, a recommendation. The syrup may be made by mixing a drachm of santonin, dissolved in a little alcohol, with eight fluidounces of syrup, of which two teaspoonfuls may be given for a dose. Santonin may also be given in the form of lozenge with sugar and tragacanth. A formula will be found in the *Am. Journ. of Pharm.* (vi. N. S., p. 124). W.

SODA.

Preparations of Soda.

SODA CAUSTICA. *Br. Caustic Soda.*

"Take of Solution of Soda *two pints*. Boil down the Solution rapidly, in a silver or clean iron vessel, until there remains a fluid of oily consistence, a drop of which when removed on a warmed glass rod solidifies on cooling. Pour the fluid on a clean silver or iron plate, and, as soon as it has solidified, break it in pieces, and preserve it in stoppered green-glass bottles." *Br.*

The solution of soda, being a solution of the caustic alkali, yields it on evaporation in the solid state. Metallic vessels are used in consequence of the chemical action of soda on earthenware or porcelain, and the product is directed to be kept in green glass bottles, because these resist its action better than those of white glass. Instead of being poured into cylindrical moulds to harden, as caustic potassa, this is allowed to solidify in mass, and is broken into irregular fragments.

As prepared by the above process, caustic soda is in grayish-white fragments, opaque, brittle, and extremely corrosive. It is deliquescent, very soluble in water, soluble in alcohol, and possessed of all the alkaline properties of potassa, from which it differs in imparting a yellow colour to flame, and in not giving in solution a yellow precipitate with bichloride of platinum, or a crystalline precipitate with tartaric acid in excess. When heated it melts, and at an intense heat evaporates. In composition, it is the hydrated oxide of sodium (NaO,HO), and cannot be deprived of its water by heat. Though deliquescent like potassa, it does not like that alkali become permanently liquid, but forms a paste, which after a time effloresces. The difference in this respect between the two alkalies is owing to the circumstance that, while both are converted into carbonates by uniting with the carbonic acid of the air, potassa forms a deliquescent, and soda an efflorescent salt. It is apt to contain impurities originating from the carbonate of soda used in preparing the solution from which it is made; and the presence of these is recognised by the Br. Pharmacopœia, when it states that the aqueous solution, acidulated with nitric acid, gives a scanty white precipitate with nitrate of silver and chloride of barium, indicating the existence of a chloride and sulphate or carbonate. According to the same authority, it leaves scarcely any sediment when dissolved in water, and 40 grains require for neutralization 90 measures of the *volumetric solution of oxalic acid*, corresponding to 27·9 grains of soda. If the solution be coloured brown by sulphuretted hydrogen or hydrosulphate of ammonia, the presence of lead may be suspected, derived probably from the glass vessels in which it has been kept. It may be used externally as a caustic in the same manner as potassa, for which purpose it may be melted and cast into sticks. It has the advantage of being less deliquescent, and probably milder.

It may be used also for making the solution of soda extemporaneously, for which purpose a drachm may be dissolved in three and a half fluidounces of distilled water. W.

SODÆ ARSENIAS. *Br.* *Arseniate of Soda.*

"Take of Arsenious Acid *ten ounces* [avoirdupois]; Nitrate of Soda *eight ounces and a half* [avoird.]; Dried Carbonate of Soda *five ounces and a half* [avoird.]; Boiling Distilled Water *thirty-five fluidounces.* Reduce the dry ingredients separately to fine powder, and mix them thoroughly in a porcelain mortar. Put the mixture into a large clay crucible, and cover it with the lid. Expose to a full red heat, till all effervescence has ceased, and complete fusion has taken place. Pour out the fused salt on a clean flagstone, and as soon as it has solidified, and while it is still warm, put it into the boiling Water, stirring diligently. When the salt has dissolved, filter the solution through paper, and set it aside to crystallize. Drain the crystals, and, having dried them rapidly on filtering paper, enclose them in stoppered bottles." *Br.*

This is a new officinal of the Br. Pharmacopœia. In the process, the arsenious acid is converted into arsenic acid at the expense of the nitric acid of the nitrate of soda, and then combines with the soda of both salts, carbonic acid and nitrous fumes being given off. As the salt consists of two eqs. of base to one of acid, each eq. of arsenious acid, having been converted into arsenic acid by two eqs. of oxygen from one eq. of the nitric acid of the nitrate, combines with the separated eq. of soda of that salt, and with another eq. of soda of the carbonate; and the three substances employed are therefore required in the proportion of their equivalents. This is almost exactly the case in the formula, the nitrate being very slightly in excess, and the carbonate about in the same proportion deficient.

Arseniate of soda is in colourless, transparent crystals, soluble in two parts of water (*Squire*), of a somewhat saline taste leaving a slight sense of acrimony, and with an alkaline reaction. Heated to 300° it melts, and loses its water of crystallization and 40·38 per cent. of its weight. "A solution of 10 grains of the residue, treated with 5·3 measures of the *volumetric solution of soda*, continues to give a precipitate with the *volumetric solution of nitrate of silver* until 161·3 measures of the latter have been added." (*Br.*) In this test the soda is added in order that, by the decomposition of the nitrate of silver, one additional eq. of oxide of silver may be furnished, so as, with the two eqs. given up in exchange for the two eqs. of soda of the arseniate of soda, to make up the three eqs. necessary for the formation of the arseniate of silver ($3AgO,AsO_5$). The precipitate is arseniate of silver, and the quantity precipitated should be equivalent to 6·16 grains of arsenic acid. Its aqueous solution gives white precipitates with chloride of barium, chloride of calcium, and sulphate of zinc (arseniates of baryta, lime, and zinc), and a brick-red precipitate with nitrate of silver (arseniate of silver).

Arseniate of soda is composed of two eqs. of soda 62, one eq. of basic water 9, one eq. of arsenic acid 115, and fourteen eqs. of water of crystallization 126 = 312; arsenic acid being tribasic. Its formula, therefore, is $2NaO,HO,AsO_5 + 14KO$.

In medical properties this salt agrees with the other preparations of arsenic (see *Acidum Arseniosum*), and may be employed for the same purposes. It is preferred by some, under the impression that it is milder than the arsenious acid or the arsenites; and, in the same dose, it certainly contains somewhat less metallic arsenic. The dose of the crystallized salt is stated at from one-twelfth to one-third of a grain; but it is generally prescribed in the form of solution. (See *Liquor Sodæ Arseniatis.*) This may be made extemporaneously by dissolving 4 grains of the anhydrous or 6·5 grains of the crystallized salt in a fluidounce of distilled water. *Pearson's arsenical solution* is an aqueous solution

of arseniate of soda, containing one grain of the salt in a fluidounce, and therefore much weaker than the officinal solution.

Off. Prep. Liquor Sodæ Arseniatis, *Br.* W.

SODÆ BICARBONAS. *U.S., Br. Bicarbonate of Soda.*

"Take of Carbonate of Soda *a convenient quantity*. Put the Carbonate, previously broken in pieces, into a wooden box, having a horizontal partition near the bottom pierced with numerous small holes, and a cover which can be tightly fitted on. To a bottle having two tubulures, and half filled with water, adapt two tubes, the first passing from an apparatus for generating carbonic acid, through one tubulure, to a point below the surface of the water in the bottle; the second reaching from the other tubulure to an opening near the bottom of the box, beneath the partition. Then lute all the joints, and cause a stream of carbonic acid to pass through the water into the box until the Carbonate is fully saturated. Lastly, remove the product from the box, and, having dried it, rub it into powder. Carbonic acid may be obtained from Marble by the addition of dilute Sulphuric Acid." *U. S.*

"Take of Carbonate of Soda *two pounds* [avoirdupois]; Dried Carbonate of Soda *three pounds* [avoird.]; White Marble, in fragments, *four pounds* [avoird.]; Hydrochloric Acid of Commerce *one gallon* [Imperial measure]; Water *two gallons* [Imp. meas.]; Distilled Water *a sufficiency*. Fill with the Marble a tubulated glass bottle having a few small holes drilled in the bottom, connect the tubulure tightly by a bent tube and corks with an empty two-necked bottle, and connect this with another bottle filled with the Carbonates of Soda well triturated together, and let the tube be long enough to reach the bottom of the bottle. Before fixing the cork in the bottle containing the Carbonate of Soda, partially immerse the bottle containing the Marble in the Hydrochloric Acid previously diluted with the Water and placed in any convenient vessel. When the whole apparatus is filled with carbonic acid gas, fix in tightly the cork of the bottle containing the carbonate of soda, and let the action go on until the gas ceases to be absorbed. Agitate occasionally for half an hour the damp salt which is formed, with half its weight of cold Distilled Water, drain the undissolved portion, and dry it by exposure to the air on filtering paper placed on porous bricks." *Br.*

The object of these processes is to unite the soda with an additional equivalent of carbonic acid, whereby it becomes converted into the bicarbonate.

The process adopted in the U. S. Pharmacopœia, since 1840, is that which has been practised for many years in the United States, and was described in 1830, by Dr. Franklin R. Smith, in the first volume of the Journal of the Philadelphia College of Pharmacy. This process is attributed to Dr. Smith by Soubeiran, who characterizes it as the best that can be employed. It was adopted in the French Codex on its revision of 1837. A stream of carbonic acid, freed from any accompanying impurity by passing through water in the intervening bottle, is conducted into a suitable vessel, containing the crystallized carbonate placed on a diaphragm, pierced with numerous holes. As the bicarbonate combines with much less water of crystallization than is contained in the carbonate, it follows that, during the progress of the saturation of the carbonate, a considerable quantity of water is liberated. This water would finally dissolve a portion of the bicarbonate formed, were it not for the pierced diaphragm, through which it is allowed to drain off holding in solution a part of the carbonate. When the saturation is completed, the pieces of crystals, still supported on the diaphragm, are found to have retained their original form, but to have become opaque and of a porous texture. The necessary carbonic acid for forming the bicarbonate may be economically obtained from other processes in which this acid is evolved; as, for example, from the process for making tartaric acid, in which tartrate of lime is formed from cream of tartar by the addition of carbonate of lime.

The British process is that of Berzelius. In the U. S. process, the excess of water over the quantity necessary for the bicarbonate is allowed to drain off; but it holds a certain portion of carbonate in solution, which thus escapes the action of the carbonic acid. To avoid this result it is only necessary to prepare a carbonate containing just sufficient water of crystallization to accommodate the bicarbonate; and the process recommended by Berzelius accomplishes that purpose. Thus, the salt which he prepares to be submitted to the carbonic acid, is an intimate mixture, in fine powder, of four parts of effloresced carbonate, with one of the crystallized salt. The proportion adopted by the Br. Pharmacopœia is different, namely, three parts of the dried carbonate to two of the crystallized carbonate; and is such as to afford an excess of water over that required to constitute the bicarbonate. Hence this process furnishes a damp salt, which is first washed with a small portion of water to free it from any remaining carbonate, and then dried in the air without heat. The apparatus employed for obtaining the carbonic acid is precisely the self-regulating generator, devised by Dr. Hare on the principle of Gay-Lussac's. The empty bottle, placed between the generating apparatus and that containing the salt, is intended, as in the U. S. process, to detain any impurity which may be carried over with the stream of carbonic acid.

Artus has given a process for obtaining bicarbonate of soda, similar to that of Wöhler for forming the corresponding salt of potassa. (See *Potassæ Bicarbonas.*) In this process, the effloresced carbonate, mixed with half its weight of freshly ignited and finely powdered charcoal, is saturated by a stream of carbonic acid, derived from the fermentation of sugar. The presence of the charcoal greatly promotes the absorption. (*Pharm. Cent. Blatt*, 1843, p. 254.)

We are informed that much bicarbonate of soda is now prepared in breweries, in the same manner as bicarbonate of potassa or sal aëratus, by placing the carbonate in suitable vessels over the fermenting beer in the vats, so as to be constantly immersed in an atmosphere of carbonic acid. It is sold under the same name as the analogous salt of potassa; but is sometimes distinguished as the *soda sal aëratus.*

Properties, &c. As obtained by the U. S. formula, bicarbonate of soda is in opaque, porous masses, made up of numerous, aggregated crystalline grains, having a snow-white colour. For the convenience of the apothecary these masses are reduced to powder. As procured by the Br. process, it is in small, white, opaque, irregular scales. Bicarbonate of soda is permanent in the air, and slightly alkaline to the taste and to turmeric paper. It is soluble in thirteen parts of cold water. When the solution is exposed to heat, the salt gradually parts with carbonic acid, and, at the temperature of 212°, is converted into sesquicarbonate. At a red heat, the water of crystallization and the second equivalent of carbonic acid, amounting together to 37 per cent., are expelled, and the anhydrous carbonate is left. One eq., or 84·3 parts of the crystallized bicarbonate, should lose, on complete decomposition by dilute sulphuric acid, two eqs. or 44 parts of carbonic acid, equal to 52·1 per cent. The salt is seldom so perfect as to satisfy this test; as good commercial samples generally contain from 2 to 3 per cent. of carbonate. "Eighty-four grains, exposed to a red heat, leave 53 of an alkaline residue, which require for neutralization 100 measures of the *volumetric solution of oxalic acid.*" *Br.* This is almost the precise proportion of carbonate of soda, which the bicarbonate should yield when deprived of its water and one eq. of carbonic acid. The presence of carbonate may be known by a decided alkaline taste and reaction, by a cold solution of the salt yielding a precipitate with sulphate of magnesia, and by a solution in 40 parts of water, affording, without agitation, an orange-coloured or reddish-brown precipitate with corrosive sublimate. The pure bicarbonate is not precipitated by bichloride of platinum, nor, when treated with nitric acid in excess, by chloride of barium or nitrate of silver.

The non-action of these tests shows the absence of salts of potassa, and of sulphates and chlorides. The incompatibles of this salt are the same as those elsewhere mentioned of the carbonate, except sulphate of magnesia in the cold, which decomposes the carbonate, but not the bicarbonate.

Composition. Bicarbonate of soda, when perfect, consists of two eqs. of carbonic acid 44, one of soda 31·3, and one of water 9 = 84·3. The London College formerly prepared this salt by a faulty process, and gave it the name of sesquicarbonate. In its Pharmacopœia of 1851, it placed the salt, under the correct name of bicarbonate, in the catalogue of Materia Medica; where, perhaps, it would properly stand, as it is now prepared in great perfection on a large scale.

Medical Properties. This salt has the general medical properties of the carbonate; but, from its mild taste and less irritating qualities, proves more acceptable to the palate and stomach. It is often resorted to in calculous cases, characterized by excess of uric acid. The continued use of the carbonate, in these cases, is liable to induce phosphatic deposits, after the removal of the uric acid. According to D'Arcet, who made the observation at the springs of Vichy, this objection does not apply to the bicarbonate, especially when taken in carbonic acid water; for this salt, by its superabundant acid, has the power of maintaining the phosphates in solution, even after the alkali has caused the uric acid to disappear. The same remark is applicable to the bicarbonate of potassa. Bicarbonate of soda has been given in infantile croup, with apparent advantage in promoting the expulsion of the false membrane, in the dose of a grain every five minutes, dissolved in milk and water. Dr. Lemaire has proposed it as an antiphlogistic remedy in the treatment of pneumonia, membranous angina, and croup, supposing it to act on the principle of removing from the blood the excess of fibrin, which exists in that liquid in inflammation. Its utility in membranous angina has been confirmed by M. Marchal (de Calvi). According to M. Jeannel, the use of bicarbonate of soda lessens the sugar in the urine of diabetic patients. The dose for an adult is from ten grains to a drachm, and is taken most conveniently in a glass of carbonic acid water. When given in angina, fifteen grains may be administered every half hour in a tablespoonful of water. This salt is principally consumed in making soda and Seidlitz powders. (See *pages* 1305, 1306.) It is sometimes made into lozenges. (See *Trochisci Sodæ Bicarbonatis.*)

Pharm. Uses. In the preparation of Aqua Acidi Carbonici, *U. S.*

SODÆ CARBONAS EXSICCATA, *U. S.*, *Br. Dried Carbonate of Soda.*

"Take of Carbonate of Soda *a convenient quantity.* Expose it to heat in an iron vessel, until it is thoroughly dried, stirring constantly with an iron spatula; then rub it into powder." *U. S.*

"Take of Carbonate of Soda *eight ounces.* Expose the Carbonate of Soda in a porcelain capsule to a rather strong sand heat, until the liquid which first forms is converted into a dry cake, and, having rubbed this to powder, enclose it in a stoppered bottle." *Br.*

Carbonate of soda contains ten equivalents of water of crystallization, and, when heated, readily undergoes the watery fusion. Upon continuing the heat, the water is dried off, and a white porous mass remains, which is easily reduced to powder. Dried carbonate of soda is in the form of a white powder, and differs in nothing from the crystallized, except in being devoid of water of crystallization. (See *Sodæ Carbonas.*) When decomposed by dilute sulphuric acid, it evolves 40·7 per cent. of carbonic acid. (*Lond. Pharm.*)

Medical Properties and Uses. This preparation was introduced into practice by Dr. Beddoes, who extolled its virtues in calculous complaints. It is applica-

be to the cure of such affections, only when dependent on a morbid secretion of uric acid. Its advantage over the common carbonate is that it admits of being made into pills, in consequence of being in the dried state. As the water of crystallization forms more than half of the carbonate, the dose of the dried salt must be reduced in proportion. From five to fifteen grains may be given three times a day, in the form of pill prepared with soap and aromatics. For the medical properties of this salt see *Sodæ Carbonas.*

Off. Prep. Sodæ Arsenias, *Br.;* Sodæ Bicarbonas, *Br.* B.

SODÆ PHOSPHAS. *U. S., Br. Phosphate of Soda. Medicinal Tribasic Phosphate of Soda.*

"Take of Bone, calcined to whiteness and in fine powder, *one hundred and twenty troyounces;* Sulphuric Acid *seventy-two troyounces;* Carbonate of Soda, Water, each, *a sufficient quantity.* Mix the powder with the Sulphuric Acid in an earthen vessel; then add eight pints of Water, and, having stirred the mixture thoroughly, digest for three days, occasionally adding a little Water to replace that which is lost by evaporation, and frequently stirring the mixture. At the expiration of that time, pour in eight pints of boiling Water, and strain through muslin, gradually adding more boiling Water until the liquid passes nearly tasteless. Set by the strained liquor that the dregs may subside, and, having poured off the clear solution, boil it down to eight pints. To the concentrated liquid, poured off from the newly formed dregs and heated in an iron vessel, add by degrees Carbonate of Soda, previously dissolved in hot Water, until effervescence ceases, and the phosphoric acid is completely saturated; then filter the liquid, and set it aside to crystallize. Having removed the crystals, add, if necessary, a small quantity of Carbonate of Soda to the liquid, so as to render it slightly alkaline; then alternately evaporate and crystallize, so long as crystals are produced. Lastly, keep the crystals in a well-stopped bottle." *U. S.*

"Take of Bone Ash, in powder, *ten pounds* [avoirdupois]; Sulphuric Acid of Commerce *fifty-six fluidounces;* Distilled Water *four gallons and a half* [Imperial measure], or *a sufficiency;* Carbonate of Soda *sixteen pounds* [avoird.], or *a sufficiency.* Place the Bone Ash in a capacious earthenware or leaden vessel, pour on the Sulphuric Acid, and stir with a glass rod until the whole powder is thoroughly moistened. After twenty-four hours, add gradually and with constant stirring a gallon [Imp. meas.] of the Water; digest for forty-eight hours, adding Distilled Water from time to time to replace what has evaporated. Add another gallon [Imp. meas.] of the Water, stirring diligently, digest for an hour, filter through calico, and wash what remains on the filter with successive portions of Distilled Water, till it has almost ceased to have an acid reaction. Concentrate the filtrate to a gallon, let it rest for twenty-four hours, and filter again. Heat the filtrate to near the boiling point, add the Carbonate of Soda previously dissolved in two gallons [Imp. meas.] of the Water, till it ceases to form a precipitate, and the fluid has acquired a feeble alkaline reaction. Filter through calico, evaporate the clear liquor till a film forms on the surface, and set it aside to crystallize. More crystals will be obtained by evaporating the mother-liquor, a little Carbonate of Soda being added if necessary to maintain its alkalinity. Dry the crystals rapidly, and without heat, on filtering paper placed on porous bricks, and preserve them in stoppered bottles." *Br.*

The incombustible part of bones is obtained by burning them to whiteness, and consists of a peculiar phosphate of lime, called bone-phosphate, associated with some carbonate of lime, &c. (See *Os.*) When this is mixed with sulphuric acid, the carbonate of lime is entirely decomposed, giving rise to effervescence. The phosphate of lime undergoes partial decomposition; the greater part of the lime, being detached, precipitates as sulphate of lime, while the phosphoric acid, set free, combines with the undecomposed portion of the phosphate, and remains in solution as a superphosphate of lime, holding dissolved a small portion of the

sulphate of lime. In order to separate the superphosphate from the precipitated mass of sulphate of lime, boiling water is added to the mixture, the whole is strained, and the sulphate washed as long as superphosphate is removed, which is known by the water passing through in an acid state. The different liquids which have passed the strainer, consisting of the solution of superphosphate of lime, are mixed and allowed to stand; and by cooling a portion of sulphate of lime is deposited, which is got rid of by decantation. The bulk of the liquid is now reduced by evaporation, and, in consequence of the diminution of the water, a fresh portion of sulphate of lime is deposited, which is separated by subsidence and decantation as before. The superphosphate of lime solution, being heated, is now saturated by means of a hot solution of carbonate of soda. The carbonic acid is extricated with effervescence, and the alkali, combining with the *excess* of acid of the superphosphate, generates one variety of the tribasic phosphate of soda; while the superphosphate of lime, by the loss of its excess of acid, becomes the neutral phosphate and precipitates. The phosphate of lime is separated by a new filtration; and the filtered liquor, which is a solution of phosphate of soda, is evaporated so as to crystallize.

In the U. S. process, the calcined bone is to the acid as 10 to 6; in the Br. process as 10 to 6½ nearly. The proportion recommended by Berzelius is as 10 to 6·66. The acid, in the officinal processes, is added to the calcined bone in the concentrated state, and afterwards diluted with more or less water. In the process given by Berzelius it is first diluted with twelve times its weight of water. All the writers state that phosphate of soda crystallizes more readily by allowing its solution to be slightly alkaline; and a remarkable fact is that a neutral solution, when it crystallizes, leaves a supernatant liquid which is slightly acid and uncrystallizable. Hence it is necessary, after getting each successive crop of crystals, to render the mother-water neutral or slightly alkaline, before it will furnish an additional quantity.

M. Funcke, a German chemist, has given the following cheap and expeditious method for obtaining phosphate of soda. To the powdered calcined bone, diffused in water, sufficient dilute sulphuric acid is added to decompose all the carbonate of lime which it contains. When the effervescence ceases, the matter is treated with nitric acid, which dissolves the phosphate of lime, and leaves the sulphate. The nitric solution of the phosphate is then treated with sulphate of soda, equal in quantity to the bone employed; and, after the reaction is completed, the nitric acid is recovered by distillation. In consequence of a double decomposition, sulphate of lime and phosphate of soda are formed, the latter of which is separated by water, and crystallized in the usual manner.

Properties, &c. The medicinal phosphate of soda is in large colourless crystals, which have the shape of oblique rhombic prisms. They are transparent at first, but speedily effloresce and become opaque when exposed to the air. It possesses a pure saline taste, resembling that of common salt. With tests it displays an alkaline reaction. It dissolves in four parts of cold, and in two of boiling water, but is insoluble in alcohol. Before the blowpipe it first undergoes the aqueous fusion, and afterwards, at a red heat, melts into a globule of limpid glass, which becomes opaque on cooling. It is not liable to adulteration, but sometimes contains carbonate of soda, from this salt having been added in excess in its preparation; in which case it will effervesce with acids. If it contain sulphate of soda, or any other soluble sulphate, the precipitate caused by chloride of barium will be a mixture of sulphate and phosphate of baryta, and will not be totally soluble in nitric acid. Chloride of barium will detect carbonate of soda also, by producing a precipitate (carbonate of baryta), soluble with effervescence in nitric acid. If a chloride be present, the *yellow* precipitate caused by nitrate of silver will be a mixed one of chloride and phosphate of silver, not entirely soluble in the same acid. The salt is incompatible with soluble salts of

lime, with which it gives a precipitate of phosphate of lime, and with neutral metallic solutions. It is found in several of the animal secretions, particularly the urine.

The medicinal phosphate of soda is one of the three tribasic phosphates of soda, characterized by having its three bases, made up of two eqs. of soda and one of water. When crystallized, it consists of two eqs. of soda 62·6, one of basic water 9, one of phosphoric acid 72, and twenty-four of water of crystallization 216 = 359·6. Its formula is, therefore, $2NaO,HO,PO_5+24HO$. When gently heated it loses its water of crystallization; and at a red heat its basic water is driven off, and the salt is converted into *pyrophosphate of soda*, or that variety of *bibasic phosphate* which has the formula $2NaO,PO_5$. This bibasic phosphate is characterized by giving a *white* precipitate with nitrate of silver. When the medicinal salt is thus dried and ignited, it loses 63 per cent. of its weight; and the residue, dissolved in water, gives with chloride of barium a precipitate entirely soluble in dilute nitric acid. (*Br.*)

Medical Properties and Uses. Phosphate of soda was introduced into practice, about the year 1800, by the late Dr. Pearson, of London. It is a mild purgative, and, from its pure saline taste, is well adapted to the cases of children, and of persons of delicate stomach. The dose is from one to two ounces, and is best given in gruel or weak broth, to which it gives a taste, as if seasoned with common salt.

SODÆ VALERIANAS. *U. S. Valerianate of Soda. Br. Appendix.*

"Take of Bichromate of Potassa, in fine powder, *ten troyounces;* Sulphuric Acid *fourteen troyounces;* Amylic Alcohol *four fluidounces;* Water *four pints;* Solution of Soda *a sufficient quantity.* Dissolve the Bichromate, with the aid of heat, in three pints of the Water, and add to the solution seven troyounces of the Sulphuric Acid, previously diluted with the remainder of the Water. Pour the liquid into a tubulated retort, to which a receiver is attached without luting. Mix the Amylic Alcohol with the remainder of the Sulphuric Acid, gradually added, and, by means of a funnel-shaped tube, passing through a cork in the tubulure of the retort and dipping into the liquid, introduce the mixture, when cool, into the retort, in small portions at a time, until it is all added. Return to the retort any liquid which may have spontaneously distilled over, and agitate the whole until the reaction has subsided, and the temperature has fallen to about 100°. Then, by means of a sand-bath, distil the liquid nearly to dryness. Introduce the distilled liquid into a capacious glass matrass, and add to it Solution of Soda, with frequent agitation, until it is accurately saturated. Separate the oil that floats on the liquid, and evaporate the latter until aqueous vapour ceases to escape, and nothing remains but the salt in a state of fusion. Lastly, pour the fused salt on a porcelain slab, and, after it has concreted, break the mass while yet warm in pieces, and keep these in a well-stopped bottle." *U. S.*

"Take of Solution of Soda *a sufficiency;* Fousel Oil *four fluidounces* [Imperial measure]; Bichromate of Potash *nine ounces* [avoirdupois]; Sulphuric Acid *six fluidounces and a half* [Imp. meas.]; Distilled Water *half a gallon.* Dilute the Sulphuric Acid with ten fluidounces of the Water, and dissolve the Bichromate of Potash in the remainder with the aid of heat. When both liquids are cold, mix them with the Fousel Oil in a matrass with occasional brisk agitation until the temperature of the mixture has fallen to about 90°. Connect the matrass with a condenser, and distil until about half a gallon of liquid has passed over. Saturate the distilled liquid accurately with the Solution of Soda, remove any oil which floats on the surface, evaporate till watery vapour ceases to escape, and then raise the heat cautiously so as to liquefy the salt. When the product

has cooled and solidified, break it into pieces, and immediately put it into a stoppered bottle." *Br.*

These processes are essentially the same as that of the late Dublin Pharmacopœia, into which the preparation was introduced in 1850. They consist of two steps; first, the artificial formation of valerianic acid, and secondly, the saturation of this acid with caustic soda. By distilling fusel oil with a mixture of sulphuric acid and bichromate of potassa, valerianic acid is formed, and passes over with water. The change is effected by the oxidizing agency of the chromic acid of the bichromate; for when fusel oil loses two eqs. of hydrogen by oxidation, and gains two of oxygen, it is converted into valerianic acid. Thus, $C_{10}H_{11}O+HO$ and $4O=C_{10}H_9O_3+HO$ and $2HO$. (See *Potassæ Bichromas* and *Alcohol Amylicum.*) The distillate, by exact saturation with the solution of caustic soda, is converted into a solution of valerianate of soda, which, by the application of heat until the water is driven off, and the residual matter is partially liquefied, furnishes, on cooling, the concrete salt. The small portion of oil that floats on the surface of the solution is valerianate of amylic ether ($C_{10}H_{11}O,C_{10}H_9O_3$).

Properties, &c. Valerianate of soda is a deliquescent, very soluble salt, in snow-white masses, having the disagreeable odour of valerianic acid, and a taste at first styptic, but afterwards sweetish. When heated to 285°, it fuses without loss of acid, and, upon cooling, concretes into a white solid. The salt, as officinally ordered, is in the form produced by fusion. It consists of one eq. of valerianic acid and one of soda ($NaO,C_{10}H_9O_3$). It has no medical applications, having been introduced into the Dublin officinal catalogue for the sole purpose of forming, by double decomposition, the valerianates of iron, quinia, and zinc, and retained in the U. S. and Br. Pharmacopœias for the preparation of the last-mentioned salt.

SPIRITUS.

Spirits.

Spirits, as the term is here used, are alcoholic solutions of volatile principles, formerly in general procured by distillation, but now frequently prepared by simply dissolving the volatile principle in alcohol or diluted alcohol. The distilled spirits are prepared chiefly from aromatic vegetable substances, the essential oils of which rise with the vapour of alcohol, and condense with it in the receiver. Some of the oils, however, will not rise at the temperature of boiling alcohol, but may be distilled with water. In this case, it is necessary to employ proof spirit or diluted alcohol, with the water of which the oil comes over in the latter part of the process. As the proof spirit of the shops is often impregnated with foreign matters, which give it an unpleasant flavour, it is better to use alcohol which has been carefully rectified, and to dilute it with the due proportion of water, as directed by the U. S. Pharmacopœia. In preparing the spirits, care should be taken to avoid the colour and empyreumatic flavour arising from the decomposition of the vegetable matter by heat. Sufficient water must, therefore, be added to cover the vegetable matter after the alcohol shall have been distilled; and, as a general rule, the heat should be applied by means of a water-bath, or of steam. The aromatic should be macerated for some days with the alcohol, before being submitted to distillation; as the oil, being thus dissolved, rises more readily with the spirituous vapour than when confined in the vegetable tissue. It is necessary, during the process, frequently to renew the water in the refrigeratory; as otherwise much of the vapour will escape condensation. A good apparatus for the purpose is described and figured in *page* 889.

The aromatic spirits are used chiefly to impart a pleasant odour and taste to mixtures, and to correct the nauseating and griping effects of other medicines. They serve also as carminatives in flatulent colic, and agreeable stimulants in debility of stomach; but their frequent use may lead to the formation of intemperate habits, and should, therefore, be avoided.

We follow the example of the Pharmacopœias, in considering in the present class several articles, which, though with the title of spirit, were formerly arranged with the substances which constitute their active ingredients, as the spirits of ammonia, ether, and nitrous ether. The Spirits, formerly official, which have been omitted in the present U. S. and Br. Pharmacopœias, are *Spiritus Carui*, Lond., Ed., *Spiritus Cassiæ*, Ed., and *Spiritus Pulegii*, Lond. W.

SPIRITUS ÆTHERIS. *Br. Spirit of Ether.*

"Take of Ether *ten fluidounces;* Rectified Spirit *one pint* [Imperial measure]. Mix. The specific gravity 0·809." *Br.*

This preparation is merely ether, diluted with twice its volume of alcohol. When prepared with materials of proper strength, its sp. gr. is 0·809. Its medical properties are similar to those of ether. The dose is from one to three fluidrachms, given with a sufficient quantity of sweetened water.

Off. Prep. Tinctura Lobeliæ Ætherea, *Br.* B.

SPIRITUS ÆTHERIS COMPOSITUS. *U.S. Compound Spirit of Ether. Hoffmann's Anodyne Liquor.*

"Take of Ether *half a pint;* Alcohol *a pint;* Ethereal Oil *six fluidrachms.* Mix them." *U. S.*

This preparation is an alcoholic solution of ether, impregnated with heavy oil of wine. In the formula, determinate measures of ether, alcohol, and oil are taken, the ether having half the volume of the alcohol. The proportion of ethereal oil has been doubled in the present edition of the U. S. Pharmacopœia; but as the oil, as now prepared, is diluted with its bulk of ether, the oleaginous strength of the compound spirit is really the same. In the late revision of the British Pharmacopœias, and their consolidation into one, this preparation has been omitted; unfortunately, we think, as there is scarcely a doubt that the influence of the ether, as a composing medicine in nervous disorder, is much increased by the oil of wine.

Compound spirit of ether is a colourless, volatile liquid, having a burning, slightly sweetish taste, and the peculiar odour of ethereal oil. If it has an empyreumatic odour, it has been badly prepared. Its sp. gr. is 0·815, according to the U. S. Pharmacopœia. When pure it is wholly volatilized by heat, and devoid of acid reaction. It becomes milky on being mixed with water, owing to the precipitation of the ethereal oil; but this change does not prove its goodness, as the same property may be given to the spirit of sulphuric ether by the addition of various fixed oils. This sophistication may be detected, according to Prof. Procter, by mixing the suspected preparation with water, drawing a piece of paper over the surface of the liquid to absorb the oily globules, and exposing the paper to heat. If the globules are fixed oil, the greasy stain will remain; if ethereal oil, the stain will disappear. When fixed oils are used to adulterate this preparation, the milkiness is generally too great, and not like the transparent, leaden milkiness of the genuine article. (*Dr. Squibb.*) "It gives only a slight cloudiness with chloride of barium; but when a fluidounce of it is evaporated to dryness with an excess of this test, it yields a precipitate [residue] of sulphate of baryta, which, when washed and dried, weighs 6·25 grains. When a few drops are burned on glass or porcelain, there is no visible residue, but the surface will be left with an acid taste and reaction. A pint of water, by the admixture of forty drops, is rendered slightly opalescent." *U. S.*

It is much to be regretted that our manufacturing chemists do not follow the

Pharmacopœia in making Hoffmann's anodyne. In rectifying crude ether, the distillation is continued as long as the ether comes over of the proper specific gravity; after which, the manufacturer has been in the habit of changing the receiver, and obtaining an additional distillate, consisting of ether and alcohol, impregnated with a little ethereal oil. Now it is this second distillate, variously modified by the addition of alcohol, ether, or water, so as to make it conform in taste, smell, opalescence, &c. to a standard preparation, kept by the manufacturer, that is sold as Hoffmann's anodyne. (See Prof. Procter's paper on Hoffmann's anodyne in the *Am. Journ. of Pharm.* for July, 1852, p. 213.) Nothing could be more uncertain in its results than a proceeding like this; and we cannot be surprised that the medicine, as obtained from different apothecaries, varies very much in properties, and often disappoints the expectations of the physician. The chief excuse for the departure from the officinal directions is the costliness of the ethereal oil; but were this much greater than it really is, the excuse would not be valid; and it cannot be justified, on any principle of morality, to sell under the officinal title a preparation which has no claim to it whatever.

Medical Properties. This preparation is intended as a substitute for the anodyne liquor of Hoffmann, which it closely resembles when properly prepared. In addition to the stimulating and antispasmodic qualities of the ether which it contains, it possesses anodyne properties, highly useful in nervous irritation, and want of sleep from this cause. These additional virtues are probably derived from the officinal oil of wine, which is a more important substance than is generally supposed. Mr. Brande believes that the only effect of it, in the preparation under notice, is to alter the flavour of the ether. In this opinion he is certainly in error. The late Drs. Physick and Dewees of this city found the officinal oil of wine, dissolved in alcohol, very efficacious in certain disturbed states of the system, as a tranquillizing and anodyne remedy. Such indeed are the generally admitted effects of Hoffmann's anodyne, when made with a due admixture of the ethereal oil. This preparation is on many occasions a useful adjunct to laudanum, to prevent the nausea which is excited by the latter in certain habits. The dose is from thirty minims to one or two fluidrachms, given in water sweetened with sugar. B.

SPIRITUS ÆTHERIS NITROSI. *U.S.*, *Br.* Spiritus Ætheris Nitrici. *U.S.* 1850. Spiritus Nitri Dulcis. *Spirit of Nitrous Ether. Sweet Spirit of Nitre.*

"Take of Nitric Acid *nineteen troyounces and a half;* Stronger Alcohol *nine pints;* Carbonate of Potassa *a troyounce.* Introduce four pints of the Alcohol into a retort, having the capacity of eight pints, and containing some pieces of glass, and add the Nitric Acid. Adapt the retort to Liebig's condenser, and apply heat by means of a water-bath so arranged that the water may be drawn off during the process. When the mixture boils briskly, draw off almost all the water of the bath, and allow the distillation to proceed spontaneously until it begins to slacken. Then cautiously reapply heat by means of the water-bath, and continue the distillation until four pints of the distilled liquid have passed over. Having thrown away the residue, rinse the apparatus thoroughly, return the liquid to the retort, add the Carbonate of Potassa to it, agitate the mixture, and again distil by means of a water-bath, slowly at first, until three pints and a half of distilled liquid have been obtained. With this mix thoroughly the remainder of the Alcohol, and transfer the mixture to half-pint bottles, which must be well stopped, and protected from the light. Spirit of Nitrous Ether has the sp. gr. 0·837, and contains from 4·3 to 5 per cent. of its peculiar ether. It should not be kept long, as it becomes strongly acid by age." *U.S.*

"Take of Nitrite of Soda *five ounces* [avoirdupois]; Sulphuric Acid *four*

fluidounces; Rectified Spirit *two pints.* Introduce the Nitrite of Soda into a matrass connected with a condenser; pour upon it the Spirit and the Sulphuric Acid, previously mixed; and distil thirty-five fluidounces, the receiver being kept very cool." *Br.**

The officinal spirit of nitrous ether is a mixture, in variable proportions, of nitrous ether (C_4H_5O,NO_3) and alcohol (rectified spirit). Nitrous ether is always generated by the reaction of nitric acid with alcohol; and it matters not whether the alcohol be mixed with nitric acid directly, or with the materials for generating it, namely, nitre and sulphuric acid. In the former U. S. Pharmacopœia the requisite nitric acid was obtained by using the materials for generating it; nitrate of potassa, namely, and sulphuric acid. The formula was modelled after a recipe communicated by Mr. John Carter, manufacturing chemist, to the Philadelphia College of Pharmacy, and recommended for adoption by a committee of that body.† The nitre and alcohol being mixed in the retort, the sulphuric acid was gradually added, and a gentle heat applied. Nitric acid was set free, and by reacting with a part of the alcohol produced the nitrous ether. Upon the subsequent increase of the heat, the ether and the remainder of the alcohol distilled over as sweet spirit of nitre. The distilled product, however, contained some acid, and hence was rectified by a distillation from carbonate of potassa. Diluted alcohol was added before commencing this distillation, to enable the operator to obtain a quantity of distilled product equal to that procured at first, without distilling to dryness, which would endanger the production of empyreuma. The alcohol was first mixed with the nitre, in the retort, and the sulphuric acid afterwards gradually added. Had the alcohol and sulphuric acid been previously mixed, the risk would have been run of generating ether before their addition to the nitre. In repeating this process the retort employed should be capable of holding twice the amount of the materials. The sweet spirit of nitre, obtained by the old formula, was estimated to contain 4 per cent. in volume of nitrous ether.

The above process, as conducted by Mr. Carter on a large scale, was performed in a copper still of about twenty gallons capacity, and furnished with a pewter head and worm. The materials for the first distillation were 18 pounds of purified nitre, 12 gallons of alcohol of 34° Baumé (0·847), and 12 pounds of sulphuric acid; and 10 gallons were drawn off. The distilled product was then mixed with a gallon of diluted alcohol, and rectified by a new distillation from lime or a carbonated alkali; the same quantity being distilled as at first. When large

* *Nitrite of Soda.* (*Br.*) The nitrite of soda used in this formula is directed in the *Appendix of the Br. Pharmacopœia* among the substances used in the preparing of medicines, with the following formula for its preparation. "Take of Nitrate of Soda *one pound* [avoirdupois]; Charcoal, recently burned, and in fine powder, *one ounce and a quarter* [avoird.]. Mix the Nitrate and the Charcoal thoroughly in a mortar, and drop the mixture in successive portions into a clay crucible heated to dull redness. When the salt has become quite white, raise the heat so as to liquefy it, pour it out on a clean flagstone, and, when it has solidified, break it into fragments, and keep it in a stoppered bottle." By this process, in theory, the nitric acid of the nitrate of soda, through the influence of charcoal and heat, loses two out of its five eqs. of oxygen, and is thus converted into the nitrous acid, which remains in combination with the soda forming the nitrite of soda (NaO,NO_3) used in the process for spirit of nitrous ether. The Pharmacopœia gives various tests of this salt; but, as produced by the Br. process, it is of uncertain composition, containing a variable proportion of the proper nitrite, never more than 25 per cent., mixed with uncertain quantities of nitrate and carbonate of soda and caustic soda. (Squire, *Comp. to Br. Pharm.*, p. 16.)—*Note to the twelfth edition.*

† The following is the formula of the U. S. Pharmacopœia of 1850. "Take of Nitrate of Potassa, in coarse powder, *two pounds;* Sulphuric Acid *a pound and a half;* Alcohol *nine pints and a half;* Diluted Alcohol *a pint;* Carbonate of Potassa *an ounce.* Mix the Nitrate of Potassa and the Alcohol in a large glass retort, and having gradually poured in the Acid, digest with a gentle heat for two hours; then raise the heat and distil a gallon. To the distilled liquor add the Diluted Alcohol and Carbonate of Potassa, and again distil a gallon." *U. S.*

quantities of this preparation are made, the several portions require to be mixed in a large glass vessel, to render the whole of uniform strength; as the portion which first comes over in the rectification is strongest in hyponitrous ether. Previously to the redistillation, the head and worm must be washed thoroughly with water, to remove a little acid which comes over in the first distillation (*Journ. of the Phil. Col. of Pharm.*, i. 308.)

In the present U. S. process, which was modelled after the plan of Dr. Squibb, the nitric acid and alcohol are directly mixed in a retort containing pieces of glass to facilitate ebullition and prevent concussion, and arrangements are made for applying heat by means of a water-bath, so that it may be diminished when necessary to repress the violence of the reaction, and increased when this requires invigoration. The liquid condensed in the receiver is mixed with carbonate of potassa, and again distilled in order to free it from the acid which has come over with the nitrous ether; and, being too strong with ether to meet the purposes required, is diluted with alcohol, and thus brought to the state of *spirit* of nitrous ether. It is a great improvement over the old formula, and has the merit of ensuring a preparation of definite strength.

The *British* process is a new one. Instead of using nitric acid either directly or by the decomposition of nitre, it substitutes nitrous acid from the nitrite of soda, separating it by means of sulphuric acid in the presence of alcohol, and thus bringing together the materials for forming the ether more nearly in the condition in which they are to exist in the ether when formed. But the intended results are not obtained by the process; for the nitrite of soda, as prepared by the British formula, is a mixture containing only a small relative proportion of the proper nitrite, which, according to Mr. Squire, exists in it in variable quantities from 5 to 25 per cent., and never exceeding the latter *amount;* so that the resulting spirit of nitrous ether must necessarily be of uncertain strength. Mr. A. J. Roberts, however, prepared a specimen, in accordance with the Br. formula, using the impure nitrite made according to the directions of the Pharmacopœia, and found it to have the sp. gr. 0·840, which approaches closely to that of the official spirit. (*Pharm. Journ.*, Jan. 1865, p. 355.)

Theory of the Production of Nitrous Ether, &c. One eq. of nitric acid, by reacting with one eq. of alcohol, forms one eq. of nitrous acid (formerly hyponitrous), one eq. of *aldehyd* ($C_4H_4O_2$), and two eqs. of water. Thus, NO_5 and $C_4H_6O_2 = NO_3$ and $C_4H_4O_2$ and $2HO$. The nitrous acid, as soon as formed, reacts with a second eq. of alcohol, so as to form one eq. of nitrous ether, with separation of one eq. of water. It has, however, been shown by Dr. Golding Bird that, when an excess of alcohol is used, *oxalhydric* (*saccharic*) *acid* is first formed, and that, when the formation of the nitrous ether has nearly ceased, aldehyd appears in the distilled product, and simultaneously oxalic acid in the contents of the retort, before which time the latter cannot be discovered. All these products result from the oxidizing action of the nitric acid upon the alcohol, increasing the proportion of oxygen in the substances formed, either by removing the hydrogen, or by abstracting this element and adding oxygen at the same time.

Properties of Nitrous Ether. *Pure* nitrous (hyponitrous) ether is pale-yellow, has the smell of apples and Hungary wines, boils at 62° (below 65° Hare), and has the sp. gr. 0·947 at 60°. The density of its vapour is 2·627. Litmus is not affected by it. When it is mixed with an alcoholic solution of potassa, hyponitrite of potassa and alcohol are formed, without producing a brown colour, showing the absence of aldehyd. It is soluble in 48 parts of water, and in all proportions in alcohol or rectified spirit. It is highly inflammable, and burns with a white flame without residue. The *impure* ether, as formerly obtained by the Edinburgh and Dublin processes for subsequent dilution to form sweet spirit of nitre, boiled at 70°, and had the density of 0·886 at 40°. The specific gravity assigned to it by the Edinburgh College was 0·899. Mixed with an

alcoholic solution of potassa, it became dark-brown, with production of *aldehyd resin*. (See *page* 14.) This discoloration showed the presence of aldehyd. When kept it became acid in a short time, as shown by litmus; and nitric oxide was given off, which often caused the bursting of the bottle. Its tendency to become acid was rendered greater by the action of the air, and depended on the absorption of oxygen by the aldehyd, which thereby became acetic acid. These facts evince the propriety of preserving this ether in small, strong bottles, kept full and in a cool place. Nitrous ether consists of one eq. of nitrous acid and one of ether, and its formula is C_4H_5O,NO_3. It was, therefore, improperly called *nitric ether*. Considered as a salt, its proper name is *nitrite of ether*. In its pure and concentrated state it is never used in medicine.

Properties of Spirit of Nitrous Ether. This is a pale-yellow, volatile liquid, of a fragrant ethereal odour, and pungent, aromatic, sweetish, acidulous taste. As usually prepared it slightly reddens litmus, but does not cause effervescence with carbonate of soda. Its officinal sp. gr. is 0·837, *U. S.*; 0·843, *Br.* The U. S. preparation contains from 4·3 to 5 per cent. of the proper nitrous ether. It keeps well in half-pint bottles, securely stopped with waxed glass stoppers, and covered with dark paper; as Dr. Squibb proved by examining some bottles thus put up, after the lapse of two years. High density is not necessarily an index of deficient strength; since it may arise from the presence of a large proportion of nitrous ether. When heated by means of a water-bath, the U. S. sweet spirit of nitre begins to boil at about 145°. If a test tube, half filled with the U. S. spirit, be plunged into water heated to 145°, and held there until its contents acquire that temperature, the spirit will begin to boil distinctly on the addition of a few small pieces of glass. (*U. S.*) Sweet spirit of nitre mixes with water and alcohol in all proportions. It is very inflammable, and burns with a whitish flame. It should not be kept long, as it always becomes strongly acid with age.

Impurities and Tests. Sweet spirit of nitre is never quite free from aldehyd; and, if the distillation be too long continued, it is apt to contain a good deal of this substance, which afterwards becomes acetic acid by absorbing oxygen. The change goes on rapidly if the preparation be insecurely kept. Aldehyd, if in considerable proportion, may be detected by imparting a pungent odour and acrid flavour, and by the preparation assuming a brown tint on the addition of a weak solution of potassa, owing to the formation of aldehyd resin. The potassa test, with the best specimens, produces a straw-yellow tint within twelve hours. "When mixed with half its volume of officinal solution of potassa, previously diluted with an equal measure of distilled water, it assumes a yellow colour, which slightly deepens without becoming brown, in twelve hours." *U. S.* Another test for aldehyd, less reliable, is the addition of an equal volume of sulphuric acid to the sweet spirit of nitre. If the sample be good, the change of colour will be slight, and the mixture will be considerably viscid; but if it contain much aldehyd, it will become dark-coloured. If water or spirit be present in undue proportion, the viscidity will be less. (*Phillips.*) Acetic acid, as well as other acids (usually nitrogen acids) that may happen to be present, may be discovered by the taste, by their acting on litmus strongly, and by their decomposing the alkaline carbonates or bicarbonates with effervescence. Nitrogen acids are known by colouring blue a piece of paper previously dipped into tincture of guaiac. These acids operate injuriously by their chemical reactions with other substances, when sweet spirit of nitre is prescribed in mixtures. Thus, they liberate iodine from iodide of potassium, gradually decolorize compound infusion of roses, and, in the compound mixture of iron, hasten the conversion of protoxide of iron into sesquioxide. To obviate these effects, Mr. Harvey, of Leeds, keeps sweet spirit of nitre standing on crystals of bicarbonate of potassa, and states that, if the preparation be of full strength, no appreciable portion of the

alkali will be dissolved. (*Pharm. Journ.*, Jan. 1842.) When acid sweet spirit of nitre is rectified from calcined magnesia, it becomes acid again in a short time; but, according to M. Klauer, when rectified from neutral tartrate of potassa, it continues unchanged for months. A deep-olive colour with sulphate of protoxide of iron shows the presence of a nitrogen oxide or acid.

According to Mr. Bastick, sweet spirit of nitre contains about one-fifth of one per cent. of anhydrous hydrocyanic acid, when made from nitrous (hyponitrous) ether, formed by impregnating alcohol with nitrous acid, evolved by the action of starch on nitric acid, according to the process of Liebig. In making sweet spirit of nitre on a large scale, Dr. Squibb found that hydrocyanic acid vapours were produced if the heat happened to rise too high, and the ether ceased to be formed.

Alcohol and water are often fraudulently added to sweet spirit of nitre. When in undue proportion, they may be detected in the British preparation, as stated in the Pharmacopœia, by agitating it with twice its volume of a saturated solution of chloride of calcium. If the sweet spirit of nitre be of the full strength, one and a half per cent. of ether will slowly separate, and rise to the surface. If less ether or none separate, the presence of too much alcohol and water will be indicated. This test is hardly applicable to the U. S. preparation, which is weaker than the British. Specific gravity is no criterion of the goodness of the preparation as obtained by any formula. The addition of water will raise its density; and the same effect will be produced by adding nitrous ether. A high density, in connection with deficient ethereal qualities, would of course indicate free acids, or an excess of water, or both. A specific gravity lower than the U. S. and Br. standard would show the presence of alcohol, either stronger than it should be, or in too large a proportion.

The fraudulent dilution of sweet spirit of nitre with alcohol and water is a great evil, considering its extensive use, and valuable remedial properties. Water is injurious, not merely as a diluent, but as the most efficient promoter of chemical changes. We have been informed that the medicine is variously diluted with twice, thrice, and even four times its weight of alcohol and water. In this way its ether strength is often reduced to less than half what it should be. Dr. Squibb examined six samples of sweet spirit of nitre, five of which were obtained from respectable wholesale druggists; and of these one sample contained 3·16 per cent. of hyponitrous ether, four between one and two per cent., and one under one per cent.; while a standard preparation, made according to the U. S. Pharmacopœia, contained at least 4·3 per cent. In some shops a strong and a weak preparation are kept, to suit the views of customers as to price. Some druggists are said to dilute their sweet spirit of nitre, upon the plea that the physician's prescriptions are written in view of the use of a weak preparation! All these evils would be corrected, if the manufacturing chemists of the Union would prepare it by the formula of the U. S. Pharmacopœia, at the same time adopting measures necessary to preserve it from change. A uniform preparation being thus furnished to the druggists, all that would be necessary on their part, would be to refrain from weakening it by the admixture of alcohol and water.

Medical Properties and Uses. Sweet spirit of nitre is diaphoretic, diuretic, and antispasmodic. It is deservedly much esteemed as a medicine, and is extensively employed in febrile affections, either alone or in conjunction with tartar emetic, for the purpose of promoting the secretions, especially those of sweat and urine. It often proves a grateful stimulus to the stomach, relieving nausea and removing flatulence, and not unfrequently quiets restlessness and promotes sleep. On account of its tendency to the kidneys, it is often conjoined with other diuretics, such as squill, digitalis, acetate of potassa, nitre, &c., for the purpose of promoting their action in dropsical complaints. Dr. Duncan, of Edinburgh, praised a combination of it with a small proportion of aromatic spirit of ammonia, as eminently diaphoretic and diuretic, and well suited to certain states of

febrile disease The dose is from thirty minims to a fluidrachm, every two or three hours, mixed with a portion of water. When used as a diuretic, it should be given in larger doses.

When the vapour of sweet spirit of nitre is inhaled, it produces, according to Mr. D. R. Brown, of Edinburgh, among other symptoms, a leaden-purple colour of the lips, mouth, hands, &c., and extreme muscular debility, enduring for hours. In his own case, these symptoms were unaccompanied with the slightest effect on the brain; but in others the effects were different; headache being invariably produced. (*Pharm. Journ.*, March, 1857, p. 456.)*

Off. Prep. Mistura Glycyrrhizæ Composita, *U. S.* B.

SPIRITUS AMMONIÆ. *U. S. Spirit of Ammonia.*

"Take of Muriate of Ammonia, in small pieces, Lime, each, *twelve troyounces;* Water *six pints;* Alcohol *twenty fluidounces.* Upon the Lime, in a convenient vessel, pour a pint of the Water, and stir the mixture so as to bring it to the consistence of a smooth paste. Then add the remainder of the Water, and mix it well with the Lime. Decant the milky liquid from the gritty sediment into a glass retort, of the capacity of sixteen pints, and add the Muriate of Ammonia. Place the retort on a sand-bath, and adapt to it a receiver, previously connected with a two-pint bottle containing the Alcohol, by means of a glass tube reaching nearly to the bottom of the bottle. Surround the bottle with ice cold water; and apply a gradually increasing heat until ammonia ceases to be given off. Lastly, remove the liquid from the bottle, and introduce it into small bottles, which must be well stopped." *U. S.*

Spirit of ammonia is now officinal in the U. S. Pharmacopœia only; the British Pharmacopœia not having adopted it. It is a solution of caustic ammonia in rectified spirit. As prepared by the U. S. process of 1850, the ammoniacal gas was received in the alcohol and condensed by it; and the proportions of the ingredients were so adjusted as to give a preparation containing between 10 and 11 per cent. of ammonia, and capable of saturating about 30 per cent. of officinal sulphuric acid. Accordingly it agreed, as it was intended it should, in ammoniacal strength, with the U. S. *Liquor Ammoniæ.* Its sp. gr. was 0·831, or thereabouts. But, in the present officinal process, the materials for the generation of ammonia are mixed with a large proportion of water, the vapour of which comes over to some extent with the gas, and is condensed along with it. The resulting spirit is, therefore, somewhat diluted with water, and to an indefinite extent, so that the preparation can have no precise sp. gr.; and, though the whole amount obtained contains all the ammonia generated, we have no accurate criterion of its relative strength.

Properties. The *U. S.* spirit of ammonia, formerly called *ammoniated alcohol*, is a transparent colourless liquid, having a strong ammoniacal odour, and acrid taste. When good it does not effervesce with dilute muriatic acid; but, if old, or carelessly kept, it is apt to be partially carbonated, as shown by this test. It, however, absorbs carbonic acid more slowly than Liquor Ammoniæ.

Medical Properties and Uses. Spirit of Ammonia is stimulant and antispasmodic, and is given in hysteria, flatulent colic, and nervous debility. It is, however, little used internally; the aromatic spirit, which is pleasanter and has similar properties, being preferred. The dose of the U. S. preparation is from ten to thirty drops in a wineglassful of water. Spirit of ammonia dissolves resins, gum-resins, camphor, and the volatile oils; and is a very convenient addition to spirituous liniments, intended to produce a rubefacient effect. Not more than one

* In relation to sweet spirit of nitre, the reader is referred to the paper of D. R. Brown, of Edinburgh, contained in the *Pharm. Journ.* (March, 1856, p. 400); also to an instructive practical paper by Dr. E. R. Squibb, U. S. Navy, published in the *Am. Journ. of Pharm.* (July, 1856, p. 289), from which we have freely drawn in revising this article.

part of the Spirit should, as a general rule, be added to six or eight parts, by measure, of the liniment. It enters into no officinal preparation. B.

SPIRITUS AMMONIÆ AROMATICUS. *U. S.*, *Br.* *Aromatic Spirit of Ammonia.*

"Take of Carbonate of Ammonia *a troyounce;* Water of Ammonia *three fluidounces;* Oil of Lemons *two fluidrachms and a half;* Oil of Nutmeg *forty minims;* Oil of Lavender *fifteen minims;* Alcohol *a pint and a half;* Water *a sufficient quantity.* Dissolve the Carbonate in the Water of Ammonia, previously mixed with four fluidounces of Water. Dissolve the Oils in the Alcohol, mix the two solutions, and add sufficient Water to make the whole measure two pints." *U. S.*

"Take of Carbonate of Ammonia *eight ounces* [avoirdupois]; Strong Solution of Ammonia *four fluidounces;* Volatile Oil of Nutmeg *four fluidrachms;* Oil of Lemon *six fluidrachms;* Rectified Spirit *six pints* [Imperial measure]; Water *three pints* [Imp. meas.]. Mix, and distil seven pints [Imp. meas.]. Sp. gr. 0·870." *Br.*

In both of these formulas carbonate of ammonia and uncombined ammonia are used; but they differ in the relative proportion of the materials and the mode of conducting the process. The U. S. spirit is a mere solution of the ingredients in alcohol diluted with a small proportion of water; while the British contains such and so much of the ingredients as may rise in distillation, and be condensed with the seven pints of spirit that result. The former is of definite strength, the latter more or less indefinite, as a portion of the materials must be left behind. The proportion of ammonia to the carbonate (sesquicarbonate) is such as to produce a neutral carbonate. The sp. gr. of the Br. preparation is 0·870.

Medical Properties and Uses. Aromatic spirit of ammonia is fitted to fulfil the same indications as the simple spirit; but is much more used on account of its grateful taste and smell. It is advantageously employed as a stimulant antacid in sick headache. The dose of the U. S. spirit is from thirty drops to a fluidrachm, sufficiently diluted with water. Aromatic spirit of ammonia may be usefully added to aperient draughts, to render them less offensive to the stomach; but care must be taken not to mix it with incompatible substances; and, in order that these may be avoided, it must be recollected that most of the ammonia contained in it is probably in the state of the neutral carbonate.

Off. Prep. Tinctura Guaiaci Ammoniata; Tinctura Valerianæ Ammoniata. B.

SPIRITUS ANISI. *U. S.* *Spirit of Anise.*

"Take of Oil of Anise *a fluidounce;* Stronger Alcohol *fifteen fluidounces.* Dissolve the Oil in the Stronger Alcohol." *U. S.*

The dose of this preparation, as a stomachic and carminative, is one or two fluidrachms. W.

SPIRITUS ARMORACIÆ COMPOSITUS. *Br.* *Compound Spirit of Horse-radish.*

"Take of Horse-radish [root], sliced, Bitter Orange Peel, dried, each, *twenty ounces* [avoirdupois]; Nutmeg, bruised, *half an ounce* [avoird.]; Proof Spirit *one gallon* [Imperial measure]; Water *two pints* [Imp. meas.]. Mix, and distil a gallon [Imp. meas.] with a moderate heat." *Br.*

This may be used advantageously as an addition to diuretic remedies, in dropsy attended with debility, especially in the cases of drunkards. The dose is from one to four fluidrachms. W.

SPIRITUS CAJUPUTI. *Br.* *Spirit of Cajuput.*

"Take of Oil of Cajuput *one fluidounce;* Rectified Spirit *nine fluidounces.* Dissolve." *Br.*

For an account of the medical properties and uses of oil of cajeput, of which

this is simply an alcoholic solution, see *Oleum Cajuputi*, in Part I. The dose of the spirit is from 10 minims to a fluidrachm. W

SPIRITUS CAMPHORÆ. *U. S.*, *Br.* *Spirit of Camphor.* TINCTURA CAMPHORÆ. *U. S.* 1850. *Tincture of Camphor.*

"Take of Camphor *four troyounces;* Alcohol *two pints.* Dissolve the Camphor in the Alcohol, and filter through paper." *U. S.*

"Take of Camphor *one ounce* [avoirdupois]; Rectified Spirit *nine fluidounces.* Dissolve." *Br.*

This is precisely the U. S. Tincture of Camphor of 1850, with a changed name. It is used chiefly as an anodyne embrocation in rheumatic and gouty pains, chilblains, and the inflammation resulting from sprains and bruises. It may also be employed internally, due regard being paid to the stimulant properties of the alcohol. The camphor is precipitated by the addition of water, but may be suspended by the intervention of sugar. The dose is from five drops to a fluidrachm, first added to sugar, and then mixed with water. W.

SPIRITUS CHLOROFORMI. *U. S.*, *Br.* *Spirit of Chloroform.*

"Take of Purified Chloroform *a troyounce;* Stronger Alcohol *six fluidounces.* Dissolve the Chloroform in the Stronger Alcohol." *U. S.*

"Take of Chloroform *one fluidounce;* Rectified Spirit *nineteen fluidounces.* Dissolve. Sp. gr. 0·871." *Br.*

The chloroform strength of these preparations is very different, the U. S. spirit having one measure of chloroform to between eight and nine of alcohol, the British one to nineteen. Solution of chloroform in alcohol in variable proportions was at one time erroneously called *chloric ether*, and was used as a respiratory anæsthetic agent in the place of chloroform, under the impression that it would be safer; the stimulant properties of the alcohol obviating the sedative action of the chloroform. It is at present, however, little if at all used in this way; they who employ chloroform, and yet wish to guard against its depressing effects, preferring ether to alcohol as the corrigent. The spirit of chloroform is a convenient form for internal exhibition, as it is more readily incorporated in mixtures than chloroform itself. The dose of the U. S. spirit is from half a fluidrachm to a fluidrachm; of the British, much more, in order to produce an equal effect; so much more, indeed, that the effect of the alcohol would neutralize in great measure that of the chloroform. The dose, however, as mentioned by British writers, is from ten to sixty minims; in which quantity, judging from our own experience, the chloroform would be of little use except for its flavour.* W.

* *Alcoholic Solution of Chloroform.* The following observations formed a part of the article on chloroform in the eleventh edition of the Dispensatory; but, with the changes in relation to this substance in the new U. S. Pharmacopœia, they find a more appropriate place here in the present edition. A preparation for inhalation, composed of one-third pure chloroform and two-thirds nearly absolute alcohol, was recommended by Dr. Warren, under the name of *strong chloric ether.* Dr. Snow has since employed a similar mixture, using equal parts of chloroform and alcohol. The mixture, made in the proportion adopted by Dr. Snow, is commended by M. Robert as the best anæsthetic agent yet proposed. As the name chloric ether was originally applied by the late Dr. T. Thomson, of Glasgow, to the Dutch liquid, it would be well to abandon the same appellation to designate chloroform, or its mixture with alcohol. A correct name for the latter would be *alcoholic solution of chloroform*, or *tincture of chloroform.* Dr. Warren used his preparation in fifty cases with success, and considered it safer than chloroform, and more agreeable than ether. Further observation is required to determine the value of "strong chloric ether" as an anæsthetic. The alcohol may prove useful by obviating, through its stimulant properties, the depressing influence of the chloroform; and ether has been occasionally mixed with chloroform, with the same view. The preparation, sold in London and elsewhere under the name of "chloric ether," is a weak tincture of chloroform of variable quality, containing at most but 16 or 18 per cent. of chloroform, and sometimes not more than 5 or 6 per cent. R

SPIRITUS CINNAMOMI. *U. S. Spirit of Cinnamon.*

"Take of Oil of Cinnamon *a fluidounce;* Stronger Alcohol *fifteen fluidounces.* Dissolve the Oil in the Stronger Alcohol." *U. S.*

The spirit of cinnamon is an agreeable aromatic cordial, and may be given in debility of the stomach in the dose of from ten to twenty drops. W.

SPIRITUS JUNIPERI. *Br. Spirit of Juniper.*

"Take of English Oil of Juniper *one fluidounce;* Rectified Spirit *nine fluidounces.* Dissolve. This Spirit contains about ninety-five times as much Oil of Juniper as the London Spiritus Juniperi." *Br.*

The spirit of juniper is used chiefly as an addition to diuretic infusions. The dose may be from twenty to sixty minims.

Off. Prep. Mistura Creasoti, *Br.* W.

SPIRITUS JUNIPERI COMPOSITUS. *U. S. Compound Spirit of Juniper.*

"Take of Oil of Juniper *a fluidrachm and a half;* Oil of Caraway, Oil of Fennel, each, *ten minims;* Diluted Alcohol *eight pints.* Dissolve the Oils in the Diluted Alcohol." *U. S.*

This spirit is a useful addition to diuretic infusions and mixtures in debilitated cases of dropsy. The dose is from two to four fluidrachms. W.

SPIRITUS LAVANDULÆ. *U. S., Br. Spirit of Lavender.*

"Take of Lavender [flowers], fresh, *twenty-four troyounces;* Alcohol *eight pints;* Water *two pints.* Mix them, and with a regulated heat, distil eight pints." *U. S.*

"Take of English Oil of Lavender *one fluidounce;* Rectified Spirit *nine fluidounces.* Dissolve." *Br.*

Mr. Brande asserts that the dried flowers produce as fragrant a spirit as the fresh. Spirit of Lavender is used chiefly as a perfume, and as an ingredient in other preparations. The perfume usually sold under the name of *lavender water* is not a distilled spirit, but an alcoholic solution of the oil, with the addition of other odorous substances. The following is given by Mr. Brande as one of the most approved recipes for preparing it. "Take of rectified spirit five gallons, essential oil of lavender twenty ounces, essential oil of bergamot five ounces, *essence of ambergris* [made by digesting one drachm of ambergris and eight grains of musk in half a pint of alcohol] half an ounce. Mix."

Off. Prep. Mistura Ferri Composita, *U. S.* W.

SPIRITUS LAVANDULÆ COMPOSITUS. *U. S.* TINCTURA LAVANDULÆ COMPOSITA. *Br. Compound Spirit of Lavender. Compound Tincture of Lavender.*

"Take of Oil of Lavender *a fluidounce;* Oil of Rosemary *two fluidrachms;* Cinnamon, in moderately fine powder, *two troyounces;* Cloves, in moderately fine powder, *half a troyounce;* Nutmeg, in moderately fine powder, *a troyounce;* Red Saunders, in moderately fine powder, *three hundred and sixty grains;* Alcohol *six pints;* Water *two pints;* Diluted Alcohol *a sufficient quantity.* Dissolve the Oils in the Alcohol, and add the Water. Then mix the powders, and, having moistened the mixture with a fluidounce of the alcoholic solution of the Oils, pack it firmly in a conical percolator, and gradually pour upon it the remainder of the alcoholic solution, and afterwards Diluted Alcohol, until the filtered liquid measures eight pints." *U. S.*

The British Pharmacopœia directs *a fluidrachm and a half* of oil of lavender, *ten minims* of oil of rosemary, *one hundred and fifty grains* of bruised cinnamon, *the same quantity* of bruised nutmeg, *three hundred grains* of red saunders, and *two pints* (Imperial measure) of rectified spirit; macerates the

solids in the spirit for seven days; then expresses, filters, dissolves the oils, and adds sufficient rectified spirit to make *two pints.*

When properly made, this is a delightful compound of spices. It is much employed as an adjuvant and corrigent of other medicines, and as a remedy for gastric uneasiness, nausea, flatulence, and general languor or faintness. The dose is from thirty drops to a fluidrachm, and is most conveniently administered on a lump of sugar, or mixed with sugar and water in a wineglass.

Off. Prep. Liquor Arsenicalis, *Br.;* Liquor Potassæ Arsenitis, *U. S.* W.

SPIRITUS LIMONIS. *U. S. Spirit of Lemon. Essence of Lemon.*

"Take of Oil of Lemon *two fluidounces;* Lemon Peel, freshly grated, *a troyounce;* Stronger Alcohol *two pints.* Dissolve the Oil in the Stronger Alcohol, add the Lemon Peel, macerate for twenty-four hours, and filter through paper." *U. S.*

This spirit is used chiefly for flavouring mixtures. W.

SPIRITUS MENTHÆ PIPERITÆ. *U. S., Br.* TINCTURA OLEI MENTHÆ PIPERITÆ. *U. S.* 1850. *Spirit of Peppermint. Tincture of Oil of Peppermint. Essence of Peppermint.*

"Take of Oil of Peppermint *a fluidounce;* Peppermint, in coarse powder, *one hundred and twenty grains;* Stronger Alcohol *fifteen fluidounces.* Dissolve the Oil in the Stronger Alcohol, add the Peppermint, macerate for twenty-four hours, and filter through paper." *U. S.*

"Take of English Oil of Peppermint *one fluidounce;* Rectified Spirit *nine fluidounces.* Dissolve. This spirit contains about forty-seven times as much Oil of Peppermint as Spiritus Menthæ Piperitæ, *Lond.*" *Br.*

The distilled spirit has no advantage over a simple solution of the oil in alcohol, and this mode of preparing it has been adopted both in the U. S. and British Pharmacopœias. The present officinal spirit is the Tincture of Oil of Peppermint of the U. S. Pharmacopœia of 1850; and is much stronger than the old distilled spirit. It has long been popularly used under the name of *essence of peppermint.* The present preparation is only about half as strong as the former tincture, and differs in having a little of the dried herb added to the oil, the object of which, as we are informed, is to impart colour to the spirit. The spirit of peppermint affords a convenient method of administering a dose of the volatile oil; being of such a strength that, when dropped on loaf-sugar, it may be taken without inconvenience. The dose is from twenty to thirty drops, which may be given as just mentioned, or mixed with sweetened water. W.

SPIRITUS MENTHÆ VIRIDIS. *U. S.* TINCTURA OLEI MENTHÆ VIRIDIS. *U. S.* 1850. *Spirit of Spearmint. Tincture of Oil of Spearmint. Essence of Spearmint.*

"Take of Oil of Spearmint *a fluidounce;* Spearmint, in coarse powder, *one hundred and twenty grains;* Stronger Alcohol *fifteen fluidounces.* Dissolve the Oil in the Stronger Alcohol, add the Spearmint, macerate for twenty-four hours, and filter through paper." *U. S.*

The remarks made on the Spirit of Peppermint are equally applicable to this. Both are usually employed as carminatives. The spirit of spearmint may be given in the dose of thirty or forty drops. W.

SPIRITUS MYRISTICÆ. *U. S., Br. Spirit of Nutmeg.*

"Take of Nutmeg, bruised, *two troyounces;* Diluted Alcohol *eight pints;* Water *a pint.* Mix them, and with a regulated heat, distil eight pints." *U. S.*

"Take of volatile Oil of Nutmeg *one fluidounce;* Rectified Spirit *nine fluidounces.*" *Br.*

The spirit of nutmeg is used chiefly for its flavour, as an addition to other medicines. The dose is one or two fluidrachms.

Off. Prep. Mistura Ferri Composita, *Br.* W.

SPIRITUS ROSMARINI. *Br. Spirit of Rosemary.*

"Take of English Oil of Rosemary *one fluidounce;* Rectified Spirit *nine fluidounces.* Dissolve. This spirit contains about thirty-one times as much Oil of Rosemary as Spiritus Rosmarini, *Lond.*" *Br.*

Spirit of rosemary is a grateful perfume, and is used chiefly as an ingredient in lotions and liniments. W.

STRYCHNIA.

Preparations of Strychnia.

STRYCHNIA. *U. S., Br. Strychnia.*

"Take of Nux Vomica, rasped, *forty-eight troyounces;* Lime, in fine powder, *six troyounces;* Muriatic Acid *three troyounces and a half;* Alcohol, Diluted Alcohol, Diluted Sulphuric Acid, Water of Ammonia, Purified Animal Charcoal, Water, each, *a sufficient quantity.* Macerate the Nux Vomica for twenty-four hours in sixteen pints of Water, acidulated with one-third of the Muriatic Acid; then boil for two hours, and strain with expression through a strong muslin bag. Boil the residue twice successively in the same quantity of acidulated Water, each time straining as before. Mix the decoctions and evaporate to the consistence of thin syrup; then add the Lime previously mixed with a pint of Water, and boil for ten minutes, frequently stirring. Pour the whole into a double muslin bag, and, having thoroughly washed the precipitate, press, dry, and powder it. Treat the powder repeatedly with Diluted Alcohol, in order to remove the brucia, until the washings are but faintly reddened by nitric acid. Then boil it repeatedly with Alcohol until deprived of its bitterness, mix the several tinctures; and distil off the Alcohol by means of a water-bath. Having washed the residue, mix it with a pint of Water, and, applying a gentle heat, drop in sufficient Diluted Sulphuric Acid to neutralize and dissolve the alkaloid. Then Add Purified Animal Charcoal, and, having boiled the mixture for a few minutes, filter, evaporate, and set aside to crystallize. Dissolve the crystals in Water, and add sufficient Water of Ammonia to precipitate the Strychnia. Lastly, dry this on bibulous paper, and keep it in a well-stopped bottle." *U. S.*

"Take of Nux Vomica *one pound* [avoirdupois]; Acetate of Lead *one hundred and eighty grains;* Solution of Ammonia, Rectified Spirit, Distilled Water, each, *a sufficiency.* Subject the Nux Vomica for two hours to steam in any convenient vessel; chop or slice it; dry it by the vapour bath or hot-air chamber, and immediately grind it in a coffee mill. Digest the powder at a gentle heat for twelve hours with two pints [Imperial measure] of the Spirit and one of the Water, strain through linen, express strongly and repeat the process twice. Distil off the spirit from the mixed fluid, evaporate the watery residue to about sixteen ounces and filter when cold. Add now the Acetate of Lead, previously dissolved in Distilled Water, so long as it occasions any precipitate; filter; wash the precipitate with ten ounces of cold Water, adding the washings to the filtrate; evaporate the clear fluid to eight [fluid]ounces, and when it has cooled add the Ammonia in slight excess, stirring thoroughly. Let the mixture stand at the ordinary temperature for twelve hours; collect the precipitate on a filter, wash it once with a few ounces of cold Distilled Water, dry it on the vapour bath, and boil it with successive portions of Rectified Spirit, till the fluid scarcely tastes bitter. Distil off most of the Spirit, evaporate the residue to the bulk of about half an ounce, and set it aside to cool. Cautiously pour off the yellowish mother-liquor (which contains the Brucia of the seeds) from the white crust of

Strychnia which adheres to the vessel. Throw the crust on a paper filter, wash it with a mixture of two parts of Rectified Spirit and one of the Water, till the washings cease to become red on the addition of nitric acid; finally, dissolve it by boiling it with an ounce of Rectified Spirit, and set it aside to crystallize. More crystals may be obtained by evaporating the mother-liquor." *Br.*

In preparing strychnia, the first step is properly to comminute the nux vomica. This may be done by rasping the seeds, or, as directed in the British Pharmacopœia, by first softening them by steam, then slicing, drying, and grinding them. The next object is to extract the strychnia. For this purpose, in the U. S. process, water is employed acidulated with muriatic acid; in the British, rectified spirit diluted with half its bulk of water. In the latter, the native igasurate of strychnia is taken up; in the former, the muriate, which is a very soluble salt. In the U. S. process, after a concentration of the infusion, the salt of strychnia is decomposed by lime, which precipitates the strychnia along with the excess of lime employed and impurities. The strychnia is extracted from the precipitate by boiling alcohol, and may be obtained in crystals by the concentration of the solution. But in this state it is much coloured and impure. To obviate these impurities in some degree, the British Pharmacopœia directs that the concentrated liquid should be treated with acetate of lead, which precipitates much of the contaminating matter, and then that the liquor, previously filtered, should be treated with ammonia, by which the strychnia is thrown down less impure than in the U. S. process. At this stage of the proceedings, the present U. S. Pharmacopœia directs that the precipitate, which, besides strychnia, contains also brucia and various impurities, should be freed from the latter alkaloid by repeated washing with cold diluted alcohol, in which brucia is much more soluble than strychnia. This is a great improvement upon the U. S. formula of 1850, in which the brucia was allowed to accompany the strychnia to the end of the process. In the U. S. process, the impure strychnia is converted into a sulphate by the addition of sulphuric acid, and precipitated again by ammonia; being, while in the state of the sulphate, decolorized by means of animal charcoal. The Br. Pharmacopœia completes the process by washing the precipitate produced by ammonia with cold water, drying it, then exhausting it with alcohol, and concentrating the alcoholic solution. The strychnia now crystallizes, leaving most of the brucia in the mother-liquor. But, as some of the latter alkaloid still contaminates the product, the Pharmacopœia directs this to be washed with cold alcohol somewhat diluted, until the washings cease to give evidence of the presence of brucia by being reddened by nitric acid; thus accomplishing at the end of the process what was done in the U. S. formula at an earlier stage. To free the strychnia entirely from brucia requires repeated crystallizations, and a little of the latter principle is consequently almost always retained; but it is not injurious, as the effects of the two alkalies upon the system are very similar. The bean of St. Ignatius yields strychnia more easily and more largely than nux vomica, but is less plentiful.*

* M. J. F. Molyn proposes, previously to the extraction of strychnia, to subject nux vomica to fermentation, by which the saccharine and gummy matters of the seeds are decomposed, and lactic acid is formed, which decomposes the igasurates of strychnia and brucia, producing with these bases very soluble lactates. For the particulars of his process, see the *Am. Journ. of Pharm.* (xix. 99).

We are informed that none of the officinal processes are followed exactly by the large manufacturers, in reference to the preliminary comminution of the nux vomica. The plan most approved is to macerate the whole seeds in dilute sulphuric acid, and to pass steam through them, under pressure, in a covered vat, lined with lead. The seeds softened in this way are then ground, and the pulp lixiviated or expressed. One advantage of the sulphuric acid, employed in this way, is thought to be the conversion of the bassorin, which impedes the process, into soluble dextrin. The liquors are precipitated with lime, and the process completed as officinally directed.—*Note to the tenth edition.*

Mr. John Horsley, of Cheltenham, England, proposes a new process for preparing

If thought desirable, brucia may be in great measure separated from the strychnia of the shops, by dissolving the latter in very dilute nitric acid, filtering, and concentrating. Nitrate of brucia crystallizes in short, thick, dense prisms grouped together; nitrate of strychnia in radiated tufts of long, light, capillary needles. By gentle agitation with the liquid, the latter salt is suspended and may be poured off, leaving the former. The alkalies may be obtained by dissolving the salts in water, and precipitating with ammonia. (*Christison.*)

As usually kept in the shops, strychnia is a white or grayish-white powder. When rapidly crystallized from its alcoholic solution, it has the form of a white, granular powder; when slowly crystallized, that of elongated octohedra, or quadrilateral prisms with quadrilateral terminations. It is permanent in the air, inodorous, but excessively bitter, with a metallic after-taste. So intense is its bitterness, that one part of it is said to communicate a sensible taste to 600,000 parts of water. It melts like a resin, but is not volatile, being decomposed at a comparatively low temperature, and entirely dissipated at a red heat. It is soluble in 6667 parts of water at 50°, and about 2000 at the boiling point. Boiling officinal alcohol dissolves it without difficulty, and deposits it upon cooling. In absolute alcohol and in ether it is very sparingly soluble. According to the experiments of Messrs. Plummer and Kelly, strychnia is soluble, at the ordinary temperature, in 387 parts of officinal alcohol (sp. gr. 0·835), 179 parts of absolute alcohol, and 682 parts of ether. (*Am. Journ. of Pharm.*, Jan. 1859, p. 25.) The volatile oils dissolve it freely. It has an alkaline reaction on test paper, and forms salts with the acids. Nitric acid does not redden it if perfectly pure, but almost always reddens it as found in the shops, in consequence of the presence of brucia. M. Eugene Marchand proposes the following test, by which a very minute proportion of strychnia may be detected. If a little of the alkaloid be rubbed with a few drops of concentrated sulphuric acid containing one-hundredth of nitric acid, it will be dissolved without change of colour; but if the least quantity of per-

strychnia, which has the advantage of dispensing with alcohol. One-quarter of a pound of nux vomica is kneaded with an equal weight of commercial acetic acid, the pulpy mass thus obtained is diluted with two or three pints of cold water, and the mixture is digested for a few days. The clear liquor is then decanted, an equal quantity of cold water poured on the mass, and digestion continued for a day or two longer, or till everything soluble has been extracted. The clear liquor is again decanted, and the residue filtered through flannel. The clear liquors are mixed, and evaporated to a syrupy consistence. The residue, when cold, is diluted with an equal quantity of water, ammonia is added in excess, and the mixture set aside for a day or two, that the strychnia may crystallize. This forms little white tufts in the liquid, and on the sides of the vessel. When the crystallization is complete, the supernatant liquid is filtered through calico, and the residue, with the impure crystals collected from the vessel added to it, is allowed to drain, then collected, and dried by means of a water-bath. The substance thus obtained, consisting of strychnia, brucia, and various impurities, is digested in hot diluted acetic acid, and the solution filtered. The strychnia and brucia may be precipitated from the filtered liquid by potassa; or, if the strychnia alone be wanted, a solution of chromate of potassa may be added, which will throw down chromate of strychnia, free from brucia, if the liquid be tolerably acid. The chromate of strychnia, being well drained on a filter, may be digested in solution of ammonia, by which the alkaloid will be precipitated of a more or less snowy whiteness. Mr. Horsley thus obtained about 1 per cent. of strychnia from nux vomica, which is at least twice the ordinary yield. (*Pharm. Journ.*, xvi. 179.)

Mr. John Williams proposes the use of benzole in the preparation of strychnia. Having extracted the soluble matters of nux vomica by repeated decoction with water acidulated with sulphuric acid, he evaporates the liquid to the consistence of thin treacle, and adds a concentrated solution of caustic potassa, so as to render the liquid strongly alkaline. He then adds an equal bulk of benzole, shakes the mixture well, and keeps it in a warm place for 12 hours. The benzole, holding the alkaloids in solution, rises, and is poured off; a new portion is added, and after similar treatment is also decanted; the mixed benzole solutions are distilled; and the residue treated with acetic acid, filtered, and precipitated with caustic soda. The precipitate is white, and consists of strychnia and brucia, which may be separated in the ordinary method. (See *Am. Journ. of Pharm.*, xxvi. 339.)— *Note to the eleventh edition.*

oxide of lead be added to the mixture, a magnificent blue colour will be instantly developed, which will pass rapidly into violet, then gradually to red, and ultimately become yellow. (*Journ. de Pharm.*, 3e *sér.*, iv. 200.) Professor Otto recommends as a test a minute quantity of solution of bichromate of potassa, which, added to the solution of strychnia in concentrated sulphuric acid, produces a splendid violet colour. (*Am. Journ. of Pharm.*, xix. 77.) A similar change of colour is produced, according to Dr. E. W. Davy, by substituting a strong solution of ferridcyanide of potassium (red prussiate of potassa) for that of bichromate of potassa. (*Ibid.*, xxv. 414.) It appears that any substance capable of yielding nascent oxygen readily will serve to develop the characteristic violet colour, when applied after the addition of sulphuric acid. Landerer has found that solid iodic acid or iodate of potassa, heated gently with strychnia, gives rise to a beautiful violet colour, gradually passing to red, which remains unchanged for many days. (*Ibid.*, March, 1861, p. 110.) According to Mr. Wm. Copney, the least efficacious agent is chlorate of potassa, a much better is deutoxide of lead, a still better is deutoxide of manganese, and the best of all is bichromate of potassa; and the general result of numerous experiments, recently made, is that the last-mentioned reagent is the most effective. The sulphuric acid must be of not less sp. gr. than 1·84; and that of 1·85 is better. The play of colours, according to Mr. Copney, is first blue, then purple, then crimson, which is followed by red and green, the latter sometimes giving place to yellow. It is stated that the 1-500,000 part of a grain may be detected. (See *Am. Journ. of Pharm.*, xxviii. 459.)* The usual mode of proceeding is to drop the solution

* This subject requires a more detailed consideration than space can be afforded for in the text. The questions have been discussed whether strychnia, taken in poisonous quantities, is decomposed after a short period in the system, so that it cannot be detected by chemical reagents either in the secretions or in the body; and whether, allowing it to remain in the system, the quantity required to produce death may not be so small, and so diffused, as to afford no evidence of its presence to chemical tests. The general results of the experiments upon these points are, that strychnia is found unaltered in the urine after being swallowed; that it strongly resists decomposition in the system; and that, in cases of poisoning, even though it may have been absorbed from the stomach, and not to be found there, it may be detected in the blood and solid tissues of the body, if taken largely enough to cause death.

But to succeed in detecting the alkaloid when mixed, in small proportion, with organic matters, it is necessary first so to disintegrate the organic matter that the action of a solvent of the strychnia should not be impeded, and that the alkaloid should be completely separated from the foreign matter. The process of Messrs. Rogers & Girdwood, by which these objects are effected, is the following. Digest the substance, supposed to contain the strychnia, with a mixture of 1 part of muriatic acid and 10 of water, until it becomes apparently fluid. Filter, and evaporate the liquid to dryness by a water-bath. Treat the residue with alcohol as long as anything is dissolved, filter, and evaporate. Dissolve the residue in water and filter. Add solution of ammonia in excess to the aqueous solution, and agitate in a bottle or long tube with half an ounce of chloroform. Upon repose the chloroform subsides, holding the alkaloid in solution. Draw it off by a pipette, and evaporate the chloroform over a water-bath. Moisten the dry residue with concentrated sulphuric acid, and expose the mixture for some hours to the temperature of a water-bath, by which means all the organic matter besides the strychnia is decomposed. Treat the charred mass with water, filter, add excess of ammonia, and shake the mixture with a drachm of chloroform. Separate the chloroform as before; and, if the matter left after the evaporation of a small portion of it is charred by concentrated sulphuric acid, the whole of it must be treated in the same manner as the previous chloroform solution. The last chloroform solution obtained is then to be tested for strychnia. Take up a little of it in a capillary tube, and drop it on the smallest space of a warm porcelain capsule, so that each successive drop may be evaporated. When the capsule is quite cold, moisten the spot with concentrated sulphuric acid, and add a minute fragment of bichromate of potassa. Should the characteristic colour not be developed, it is said that, if there be the minutest quantity of strychnia present, the colour will become visible by adding sulphuric acid rendered slightly yellow by chromic acid. In conducting the process, care must be taken not to stir the spot moistened by sulphuric acid with a rod before the addition of the bichromate, and not to expose the spot to a very strong light, which interferes with the chemical

suspected to contain strychnia upon a clean surface of porcelain, evaporate to dryness, then apply the sulphuric acid to the spot, and afterwards a minute fragment of a crystal of the bichromate, which will immediately produce the change of colour. Some doubt was thrown upon the value of this test by experiments, which seemed to prove that the presence of morphia in excess, especially in connection with organic matter, so far modified or disguised the action of the test upon strychnia as to prevent the appearance of the characteristic colour; but subsequent and carefully conducted experiments, by the late Dr. Robert P. Thomas, satisfactorily determined that the conclusions in relation to the effects of morphia were erroneous, and that, whether alone or associated with organic matters, in small or in large quantity, it does not prevent the operation of this colour-test if carefully applied. (*Am. Journ. of Med. Sci.*, Oct. 1861, p. 414; and April, 1862, p. 340.) Strychnia consists of carbon, hydrogen, nitrogen, and oxygen; but the proportion of its constituents is very differently given by different authors. Liebig states the composition to be $C_{44}H_{23}N_2O_4$; in the British Pharmacopœia, it is given as $C_{42}H_{22}N_2O_4$, which is the formula inferrible from the analysis of Gerhardt. (See *Am. Journ. of Pharm.*, March, 1859, p. 135.) The salts of strychnia are for the most part soluble and crystallizable. Their solution is decomposed by the alkalies and their carbonates, and by tannic, but not by gallic acid; and is not affected by the salts of sesquioxide of iron. They are precipitated by the solution of iodine in iodide of potassium, and the precipitate, though soluble in alcohol, is insoluble in the diluted acetic and muriatic acids of the U. S. Pharmacopœia. (Fairthorne, *Am. Journ. of Pharm.*, xxvii. 212.)*

reactions. (*Lond. Med. Times and Gaz.*, June, 1857, p. 620.) It is probable that the process of dialysis might be advantageously applied to the separation of strychnia from the organic matters containing it, when brought to the liquid state. (See *Dialysis*, page 896.) Diluted acetic acid may be used for extracting the alkaloid with other soluble substances from the contents of the stomach.

It is stated by Mr. C. W. Bingley that, if much tartar emetic be contained in a solution with a little strychnia, a pale-greenish colour is produced instead of the violet; and, in like manner, if chloride of antimony be present, the sulphuric acid and bichromate of potassa test fails altogether. (*Chem. Gaz.*, June 16, 1856, p. 229.) Mr. Richard Hagen, having been induced, by the assertion of Von Sicherer that this test fails when the strychnia is mixed with tartar emetic or other tartrates, or even tartaric acid, to investigate the subject, ascertained that this statement, as a general rule, is erroneous; for the reaction takes place with strychnia or its muriate, though mixed with 20 or 30 parts of tartrate of antimony; yet when *nitrate of strychnia* is used with 20 parts of the antimonial tartrate, the mass almost instantly acquires a green colour with the reagents mentioned. But even with nitrate of strychnia, the test succeeds if peroxide of lead is used instead of chromic acid as the oxidizing agent. (*Ibid.*, Oct. 15, 1857, p. 398.)

For a particular account of the results produced by the reaction of a large number of substances with strychnia, the reader is referred to a paper by Dr. T. G. Wormley, in the *Chemical News* for April 14th and 28th, 1860 (pp. 218 and 242). Among other trials made by him was that of the action of this alkaloid on frogs, proposed as a test by the late Dr. Marshall Hall. The poison was injected into the stomach of the animals through a pipette. A solution containing 1 per cent. of strychnia immediately produced rigidity and violent tetanic spasms, and death in 8 minutes. With 1 part of strychnia to 1000 of the menstruum, the spasmodic symptoms were induced in 3 or 4 minutes; with 1 in 10,000, in from 10 to 24 minutes; with 1 in 20,000, and 1 in 30,000, the symptoms were less unequivocal, though tetanic spasms were noticed in some of the animals.

Experiments by Mr. W. A. Guy on the effects of sulphuric and nitric acids on strychnia and many other alkaloids, published with tabulated results, show that in no one out of 66 proximate principles, chiefly alkaloids, was the same change of colour produced as in strychnia by concentrated sulphuric acid, followed by a crystal of bichromate of potassa. (See *Am. Journ. of Pharm.*, Nov. 1861, p. 517.) In the same number of the same journal (p. 527) is a paper by Mr. T. E. Jenkins, giving the result of experiments with sulphuric acid and bichromate of potassa on numerous alkaloids, all tending to prove the delicacy and certainty of this colour-test of strychnia.—*Note to the eleventh and twelfth editions.*

* When an aqueous solution of sulphate of strychnia and nitrite of potassa is boiled, an effervescence takes place owing to the escape of nitrogen, and the solution becomes yellow.

Strychnia is apt to contain impurities, of which the chief, besides brucia, are colouring matter, and lime or magnesia. The two latter impurities are left behind when the adulterated alkaloid is incinerated in the open air. Pure strychnia leaves no ashes under these circumstances. Brucia is detected by the red colour which it yields with nitric acid. Neither this nor sulphuric acid colours strychnia; a test which serves to distinguish it from several other alkaloids.

Medical Properties and Uses, &c. The effects of strychnia upon the system are identical in character with those of nux vomica, and it is employed for the same purposes as a medicine. (See *Nux Vomica*, page 561.) It operates in the same way by whatever avenue it may enter into the circulation; but is said to act most powerfully when injected into the veins, or applied to a fresh wound. The blood of an animal under its influence produces similar effects in another, if transfused into its veins. There is no doubt that it is absorbed; as, after having been swallowed, it has been found in the urine, the blood, and the tissue of various organs. In overdoses it is a most violent poison. Pelletier and Caventou killed a dog in half a minute with one-sixth of a grain of the pure alkaloid. One grain or even less might prove fatal in the human subject. A case, however, is recorded in which recovery took place after seven grains had been swallowed; but the medicine was probably impure. (See *Am. Journ. of Med. Sci.*, N. S., xxx. 562.) Its most striking and characteristic effect, when taken in poisonous doses, is violent tonic spasms of the muscles, like those of tetanus, which sometimes continue after death. According to M. Duclos, the poisonous effects of strychnia upon animals subside under the application of negative electricity, while they are aggravated by the positive. (See *Am. Journ. of Pharm.*, xvi. 154.) M. Boudet has found that chlorine water alternated with tartar emetic, so as to produce vomiting, obviates these effects in dogs. (*Arch. Gén.*, Feb. 1853, p. 222.) Kermes mineral has been recommended by M. Thorel as an antidote, being thought by him to form with strychnia an insoluble sulphuret, at the same time aiding any other emetic which may be administered for its expulsion. In cases of poisoning with strychnia he recommends fifteen grains of kermes, and one and a half grains of tartar emetic. MM. Bouchardat and Gobley state that, out of the body, the iodureted iodide of potassium acts far more powerfully in producing an absolutely insoluble compound. (See *Am. Journ. of Pharm.*, xxiii. 84.) Animal charcoal has been employed with a view to absorb the poison; being thrown in by means of a stomach-tube. (*Lond. Med. Times and Gaz.*, April, 1855, p. 423.) Tannic acid, chlorine, and the tinctures of iodine and bromine are recommended as the best antidotes by Prof. Bellini. (See *Am. Journ. of Med. Sci.*, July, 1863, p. 276.) The indications are to evacuate the stomach, using at the same time any chemical antidote that may be at hand, and to relieve the spasms by opiates, ether, or other narcotics. Of the emetics sulphate of zinc would be among the most efficient; and powdered mustard has been highly recommended. They should be aided by the very free use of warm water. But it often happens that, before aid arrives, enough of the poison has been absorbed to produce death; so that vomiting, even aided by chemical antidotes, cannot

If ammonia be now added, a precipitate takes place, which has been found to consist of two new alkaloids, resulting from the oxidation of the strychnia in different degrees. One of these the discoverer, P. Schutzenberger, proposes to name *oxystrychnia*, and the other *binoxystrychnia*. (See *Am. Journ. of Pharm.*, March, 1859, p. 133.)

Methyl-strychnia. Methyl-brucia. These alkaloids are formed by replacing one of the eqs. of hydrogen in strychnia by methyl (C_2H_3), which is effected by acting on the alkaloids by iodide of methyl. A singular and, if verified, very important statement in relation to these modifications of strychnia and brucia, made by Stahlschmidt (*Ann. der Phys. und Chem.*), is that they are not poisonous. He gave to a rabbit five grains of methyl-strychnia, without any bad symptoms, though the same animal was afterwards killed in five minutes by one-twentieth of a grain of strychnia placed upon its tongue. The important practical inference is that iodide of methyl ought to be an antidote to strychnia. (See *Am. Journ. of Pharm.*, May, 1860, p. 220.)—*Note to the twelfth edition.*

be relied on. To relieve the spasm, besides opium and ether, camphor has been used with supposed success; and several cases are on record in which the inhalation of chloroform has not only afforded great relief, but appears to have been the means of saving life. Chloroform has been used also with seeming advantage by the stomach. In a case recorded by Dr. Dresbach, of Tiffin, Ohio, two drachms, swallowed by a patient alarmingly ill from the effects of three grains of strychnia, produced complete relief in less than fifteen minutes. (*Am. Journ. of Med. Sci.*, xix. 546, from *Western Lancet*, Feb. 1850.)* A case occurring at St. Louis, Missouri, is on record, in which a patient, who had taken six grains of strychnia, was, after having been vomited, apparently saved by the internal use of infusion of tobacco, administered by Drs. Byrne and O'Reilly. (*Ranking's Abstract*, No. 29, p. 287.) Aconite has been shown by experiments on dogs, performed by Dr. Woakes, to have a similar physiological antagonism with strychnia, and has been recommended in poisoning by this alkaloid, after evacuation of the stomach. (*British Med. Journ.*, Oct. 26, 1861.) Different persons are very differently susceptible to the action of strychnia, and some are powerfully affected by the smallest doses. Besides, being more or less impure as kept in the shops, it cannot be relied on with certainty. Hence the necessity of great caution in prescribing it, and of carefully watching the patient during its use. The best plan is always to begin with very small doses, and gradually increase till its effects are observed. From one-sixteenth or even one-twenty-fourth to one-twelfth of a grain internally, and from an eighth to one-third of a grain externally, upon a blistered surface, may be employed at first; and afterwards increased if necessary. It is most conveniently administered in the form of pill. It may be given also in the saline state, which is produced by dissolving it in water acidulated with sulphuric, muriatic, nitric, or acetic acid. For its therapeutical applications, see *Nux Vomica* in *Part I.* Dr. Isaac Hays, of Philadelphia, has found a solution of acetate of strychnia, dropped into the eye, to possess powers similar to those of the Calabar bean, in producing contraction of the pupil, and influencing the muscles of accommodation, and has been for several years in the habit of using it for this purpose. (*Am. Journ. of Med. Sci.*, July, 1863, p. 266.)

Off. Prep. Strychniæ Liquor, *Br.;* Strychniæ Sulphas, *U. S.* W.

STRYCHNIÆ SULPHAS. *U. S. Sulphate of Strychnia.*

"Take of Strychnia *a troyounce;* Dilute Sulphuric Acid *nine fluidrachms,* or *a sufficient quantity;* Distilled Water *a pint.* Mix the Strychnia with the Distilled Water, heat the mixture gently, and gradually add Diluted Sulphuric Acid until the alkaloid is neutralized and dissolved. Filter the solution, and evaporate with a moderate heat, so that crystals may form on cooling. Lastly, having drained the crystals, dry them rapidly on bibulous paper, and keep them in a well-stopped bottle." *U. S.*

This salt is in colourless prismatic crystals, efflorescent on exposure, inodorous, extremely bitter, freely soluble in water, sparingly soluble in alcohol, and insoluble in ether. It melts with a moderate heat, losing nearly 14 per cent. of water of crystallization, and by a strong heat is completely dissipated. The chief advantage of this preparation over strychnia is its solubility in water, by which it is better adapted to external use, as for application to blistered surfaces, or for subcutaneous injection, should this at any time be deemed advisable, or as an ingredient in collyria. But even these advantages may be so easily gained by

* In a letter to the authors, from Dr. Wm. D. Barclay, dated Muscatine, Iowa, May 4th, 1863, the case of a robust young man is described, who, after taking four grains of strychnia, was seized with the most violent tetanic spasms, accompanied with intense suffering, and recovered under the use of chloroform, given both internally and by inhalation. It was necessary to keep him under the influence of the medicine for thirteen consecutive hours, during which two pounds of chloroform were consumed by inhalation. Two drops were given every five minutes, by the stomach, when the mouth could be opened.—*Note to the twelfth edition.*

adding a few drops of an acid, the acetic, for example, to strychnia, as much to diminish the value of this as a distinct officinal preparation. The dose is the same as that of the alkaloid itself. W.

SUCCI. *Br.*

Juices.

Though introduced to professional notice by Mr. Squire, so long since as in the year 1835, and subsequently used by many practitioners, the Juices have now for the first time been made officinal, as a distinct class of preparations. They consist of the expressed juices of fresh plants, preserved by the addition of one-third of their bulk of alcohol. Considering the great inequality in strength, and of course uncertainty in operation of the fresh juices themselves, according to soil, climate, mode of cultivation, season, and age of the plant, it may be questioned whether they merit the prominence which has been given them in the British Pharmacopœia. Only three of them have been made officinal.

SUCCUS CONII. *Br. Juice of Hemlock.*

"Take of Fresh Leaves of Hemlock *seven pounds;* Rectified Spirit *a sufficiency.* Bruise the Hemlock in a stone mortar; press out the juice; and to every three measures of juice add one of the Spirit. Set aside for seven days, and filter. Keep it in a cool place." *Br.*

The albumen is probably coagulated under the influence of the alcohol; and hence the propriety of directing filtration. The dose of this preparation is from 30 to 90 minims. It is probably quite as reliable as the tincture. W.

SUCCUS SCOPARII. *Br. Juice of Broom.*

"Take of Fresh Broom Tops *seven pounds;* Rectified Spirit *a sufficiency.* Bruise the Broom Tops in a stone mortar; press out the juice; and to every three measures of juice add one of the Spirit. Set aside for seven days, and filter. Keep it in a cool place." *Br.*

The dose of this preparation as a diuretic is from 30 minims to a fluidrachm. In large doses it would be apt to disturb the stomach and bowels. It is more appropriately used as an adjuvant to other diuretics than alone. W.

SUCCUS TARAXACI. *Br. Juice of Taraxacum.*

"Take of Dandelion Root *seven pounds;* Rectified Spirit *a sufficiency.* Bruise the Dandelion Root in a stone mortar; press out the juice; and to every three measures of juice add one of the Spirit. Set aside for seven days, and filter. Keep it in a cool place." *Br.*

The dose of this juice is from two fluidrachms to half a fluidounce.* W.

* *Preserved Juice of Taraxacum.* Mr. Donovan proposes the following plan, by which the juice of taraxacum may be obtained and preserved throughout the year, with nearly all its native efficiency. The whole herb, immediately after collection, is to be washed, bruised, and expressed; and the residue, having been mixed with as much water at 200° as will bring it to the consistence of a pulp, is to be allowed to stand for two hours, and then again expressed. The liquids thus obtained are to be mixed, and very slowly evaporated, in a wide earthen vessel, and with constant agitation, to one-half. The salts are thus obtained, though with little of the bitter principle. To supply this, a quantity of the roots equal to the weight of the herb first employed, is to be bruised and expressed. The resulting juice, which is in small quantity and bitter, is to be set aside; while the residual marc is to be mixed with the concentrated juice already prepared, previously brought to a boiling heat. When cold, the mixture is to be strongly expressed, and the liquor obtained to be mixed with one-sixth of its measure of alcohol. The liquor is then to be poured into quart bottles, but so as not to fill them. These are to be immersed in a vessel containing water as high as the liquid within them, and placed over a fire; the water is to be slowly heated to 180°; the bottles are to be withdrawn; and the reserved juice of the root is to be added to each in equal quantities. The space at first left in the bottles should be such that, after the addition of the juice, and the driving in of the cork, as little as possible

SULPHUR.

Preparations of Sulphur.

SULPHUR PRÆCIPITATUM. *U. S.*, *Br.* Lac Sulphuris. *Precipitated Sulphur. Milk of Sulphur.*

"Take of Sublimed Sulphur *twelve troyounces;* Lime *eighteen troyounces;* Muriatic Acid, Water, each, *a sufficient quantity.* Pour sufficient Water on the Lime to slake it, and, having mixed the Sulphur with it, add fifteen pints of Water to the mixture; then boil for two hours, occasionally adding Water to preserve the same measure, and filter. Dilute the filtered liquid with an equal bulk of Water, and drop into it Muriatic Acid so long as a precipitate is produced. Lastly, wash the precipitated Sulphur repeatedly with Water until the washings are nearly tasteless, and dry it." *U. S.*

"Take of Sublimed Sulphur *five ounces* [avoirdupois]; Slaked Lime *three ounces* [avoird.]; Hydrochloric Acid *eight fluidounces*, or *a sufficiency;* Distilled Water *a sufficiency.* Heat the Sulphur and Lime, previously well mixed, in a pint [Imperial measure] of the Water, stirring diligently with a wooden spatula, boil for fifteen minutes, and filter. Boil the residue again in half a pint [Imp. meas.] of the Water, and filter. Let the united filtrates cool, dilute with two pints [Imp. meas.] of the Water, and, in an open place or under a chimney, add in successive quantities the Hydrochloric Acid previously diluted with a pint [Imp. meas.] of the Water, until effervescence ceases and the mixture acquires an acid reaction. Allow the precipitate to settle, decant off the supernatant liquid, pour on fresh Distilled Water, and continue the purification by affusion of Distilled Water and subsidence, until the fluid ceases to have an acid reaction and to precipitate with oxalate of ammonia. Collect the precipitated sulphur on a calico filter, wash it once with Distilled Water, and dry it at a temperature not exceeding 120°." *Br.*

In the U. S. process three eqs. of lime react with six of sulphur, so as to form two eqs. of bisulphuret of calcium, and one of hyposulphite of lime ($3CaO$ and $6S = 2CaS_2$ and CaO,S_2O_2). On the addition of the muriatic acid, six eqs. of sulphur are precipitated (four from the two eqs. of bisulphuret of calcium and two from the one eq. of hyposulphite of lime), and the calcium and oxygen unite with the muriatic acid, so as to form chloride of calcium and water. This rationale is not exactly applicable to the British process, in which the proportion of the sulphur to the lime employed is much greater than in that of the U. S. Pharmacopœia. The muriatic acid is the most eligible precipitant for the sulphur; as it gives rise to chloride of calcium, which is a very soluble salt, and easily washed away. Sulphuric acid is wholly inadmissible; as it generates sulphate of lime, which, from its sparing solubility, becomes necessarily intermingled with the precipitated sulphur. According to Schweitzer, the best material from which

should remain. The corks, being now cut off close to the glass, are to be covered with hard sealing-wax; and the bottles set by, inverted, in a cool place. The alcohol used is alone insufficient for the preservation of the juice; and hence the necessity of heating the bottles, and sealing them when quite full, according to *Appert's process.* Each ounce will contain about a drachm of the alcohol. (See *Am. Journ. of Pharm.*, xxiv. 65.)

Professor Procter proposes the following plan. Of the fresh roots collected in September or October, twenty pounds avoirdupois are to be sliced transversely, reduced to a pulpy mass by grinding or contusion, then thoroughly incorporated with four pints of alcohol of 0·835, and set aside in stoneware jars. After a week, or a longer time, the pulpy mass is to be subjected to strong pressure, and the liquid filtered and bottled for use. Even after six months the pulp thus treated preserves the sensible properties of the dandelion in a marked degree. Should the alcohol in the expressed liquor be objected to, it may be partially removed by a gentle evaporation by means of a water-bath until the bulk of the juice has been diminished one-sixth, and then adding eight ounces of sugar for every pint. (*Ibid.*, xxv. 408.)—*Note to the tenth edition.*

to precipitate the sulphur is the sulphuret of potassium, formed by boiling sulphur with caustic potassa. Dr. Otto, of Brunswick, finds that sulphuret of potassium is apt to contain sulphuret of copper, and therefore prefers sulphuret of calcium. (*Pharm. Cent. Blatt*, Jan. 1845.)

Properties, &c. Precipitated sulphur is in friable lumps, having a white colour, with a pale yellowish-green tint, and consisting of finely divided particles slightly cohering together. It is entirely dissipated by heat. Water boiled upon it should not redden litmus. When recently prepared, it is devoid of taste, but possesses a peculiar smell. When long exposed, in a moist state, to the air, it becomes strongly contaminated with sulphuric acid. From its colour it was formerly called *lac sulphuris* or *milk of sulphur*. It is insoluble in water, but dissolves in a boiling solution of caustic potassa, and in oil of turpentine by the aid of heat. When of a brilliant white colour, the presence of sulphate of lime may be suspected; in which case the preparation will not be wholly volatilized by heat. If pure it communicates a harsh feel when rubbed between the fingers, owing to the friction of the crystalline particles. (*Dr. Bridges.*) We have seen a sample of so-called precipitate of sulphur, which consisted almost entirely of sulphate of lime. Precipitated sulphur differs from sublimed sulphur in being in a state of more minute division, and in presenting, after fusion, a softer and less brittle mass. Its peculiarities are supposed to depend upon the presence of water, which, however, is found in too small a quantity to constitute a regular *hydrate*. According to Rose, its white colour is occasioned by the presence of a small proportion of bisulphuretted hydrogen. Soubeiran states that it always contains some sulphuretted hydrogen, which causes it to differ as a therapeutic agent from sublimed sulphur.

Medical Properties and Uses. Precipitated sulphur possesses similar medical properties to those of sublimed sulphur. It is the form of sulphur used by Dr. Fuller, of London, as an external application in sciatica and chronic rheumatism. (See *Sulphur*, Part I.) Its state of extreme division renders it more readily suspended in liquids; but its liability to become acid by keeping is an objection to it. It is sometimes selected for forming ointments, which have the advantage of being of a lighter colour than when made with sublimed sulphur. The dose is from one to three drachms. B.

SULPHURIS IODIDUM. *U. S. Iodide of Sulphur. Bisulphuret of Iodine.*

"Take of Iodine *four troyounces*; Sublimed Sulphur *a troyounce*. Rub them together until they are thoroughly mixed. Introduce the mixture into a flask, close the orifice loosely, and apply a gentle heat so as to darken the mass without melting it. When the colour has become uniformly dark throughout, increase the heat so as to produce liquefaction. Then incline the flask in different directions, in order to return into the liquid any portions of Iodine which may have been condensed on the inner surface of the vessel. Lastly, withdraw the heat, and, when the liquid has congealed, remove the mass by breaking the flask, reduce it to pieces, and keep these in a well-stopped bottle." *U. S.*

This preparation, though formerly officinal with the London and Dublin Colleges, does not retain a place in the British Pharmacopœia.

The U. S. process is that of the French Codex. It simply effects a combination of the two ingredients.

Properties, &c. Iodide of sulphur has a grayish-black colour, and radiated crystalline appearance like that of sulphuret of antimony. Its smell resembles that of iodine, and it stains the cuticle in a similar manner. It dissolves in sixty parts of glycerin, forming a solution which would probably prove useful, in some cases, as a substitute for the ointment of this iodide. It is rapidly decomposed, when in a state of powder, upon the addition of several of the volatile oils, violet vapours of iodine being evolved, and the smell of sulphur perceived. (*Dr. G. W.*

Patterson.) It is entirely volatilized by heat, and by continued boiling with water is wholly decomposed, iodine escaping with the steam, and sulphur being left nearly pure. The proportion of sulphur thus obtained is about 20 per cent. (*Lond. Pharm.*) This result shows that the compound is a bisulphuret. Iodide of sulphur has been very usefully employed as an external remedy in various skin diseases, such as tinea capitis, lupus, lepra, &c., applied in the form of ointment. (See *Unguentum Sulphuris Iodidi.*) It has been used internally, associated with iodide of potassium and senna, in the form of a syrup, in scrofulous and cutaneous diseases. (*E. Levrat.*) This syrup contains ioduretted iodide of potassium, and free sulphur, in consequence of a reaction which takes place between the two iodides. In a case of glanders in the human subject, which terminated in recovery under the care of M. Bourdon, of Paris, the iodide of sulphur was used internally, and was thought to have exercised a favourable influence. (*Ann. de Thérap.*, 1858, p. 239.)

Off. Prep. Unguentum Sulphuris Iodidi. B.

SUPPOSITORIA. *Br.*

Suppositories.

As a class of officinal preparations, suppositories have been introduced into the British Pharmacopœia; and they would seem to have a claim to this position quite as strong as the *Enemata*, which have long been officinally recognised. Indeed, provision has been made in the U. S. Pharmacopœia for such a class, by the introduction into the Materia Medica Catalogue of the butter of cacao (Oleum Theobromæ), which, beyond all other substances, is peculiarly calculated for their preparation. Suppositories are solid bodies intended to be introduced into the rectum, with the view either of evacuating the bowels by irritating the mucous membrane of the rectum, or of producing a specific effect on the neighbouring parts, or on the system at large. They fulfil the same indications as enemata, and are sometimes preferable from the facility of their application, and, when the object is to produce the peculiar effect of a medicine, from the smallness of their bulk, which facilitates retention. Their form may be cylindrical, conical, or spherical; the last being preferable when the bulk is small. They should be of such a consistence as to retain their shape, but so soft as to incur no risk of wounding the rectum. For laxative purposes the suppository may be from one to three inches long, and about as thick as a common candle; with a view to the specific effects of medicines, it should be considerably smaller, as in this case it is important that the medicines should be retained, and the irritative influence of distention avoided. Soap is not unfrequently employed in this way as a laxative. A piece of solidified molasses (molasses candy) is sometimes preferred. To increase the purgative effect, and at the same time act on the uterine function, aloes may be added to the soap. Mr. A. B. Taylor, of Philadelphia, some years since called attention to *cocoa butter*, already familiar to French pharmacy, as the best excipient for solids administered by the rectum, having more exactly the requisite degree of consistence and fusibility than any combination of suet, spermaceti, wax, &c., that could be employed. (*Am. Journ. of Pharm.*, July, 1852, p. 211.) Experience has shown that the consistence of cacao butter for this purpose may be improved by incorporating it with a little wax, from one-fifth to one-eighth of its weight. This may be done by melting the two together at the time of preparing the suppositories; or the mixture may be kept ready-made on hand. In preparing the suppository, the excipient should be liquefied by a gentle heat, the medicine then incorporated with it, and the mixture poured into suitable moulds to harden. A convenient weight for each suppository is about twenty-five grains; but this may be much lessened or increased as circumstances may seem to de-

mand.* It has been recommended to form the excipient into the required shape, and then, while it is still soft, make an excavation from the base upward, into which the medicine may be introduced, and afterwards enclosed by a little of the cacao butter. But as one of the objects of the excipient is an equable diffusion of the medicine to prevent irritation, this method would be altogether inapplicable to substances in any degree locally irritant. Opium, or some one of its preparations, is very advantageously administered in the form of a suppository, in cases of irritation of the rectum, urinary passages, or genital apparatus. The other narcotics may be used in the same way; and indeed any other medicine, in reference to its effects on the system, provided the quantity be not too large, and the local effects not too irritant. Tannic acid or other astringent substance may also very appropriately be employed in this way in cases of prolapsus, or other affection depending on relaxation of the rectum or anus. The dose may in general be three times that of the medicine given by the mouth. W.

SUPPOSITORIA ACIDI TANNICI. *Br. Suppositories of Tannic Acid. Tannin Suppositories.*

"Take of Tannic Acid *twenty-four grains;* Glycerine *twenty minims;* Prepared Lard, White Wax, each, *a sufficiency.* Melt eighty grains of the Lard and forty grains of the Wax in a water-bath, and, when nearly cold, add the Tannic Acid previously well mixed with the Glycerine. When the mixture has solidified, divide the mass into twelve equal portions, to be formed into cones, which are to be allowed to stand till they acquire sufficient firmness. Dip each cone into a mixture of three parts of the Wax and eight of the Lard, kept melted in a water-bath, and set aside in a cool place, that the coating may become hard." *Br.*

Though the British Pharmacopœia has only two suppositories, it is to be supposed that the intention of its framers was not to limit the number employed so narrowly, but to present a model form, after which others might be prepared. It is certain that a good choice has been made; for, omitting the mere laxative suppository, none are perhaps so frequently used as those of tannic acid, and some one of the preparations of opium. The last part of the process is probably to give a coating to the suppository somewhat firmer than its interior substance, which must be softened by the glycerin. It is doubtful whether, in our hot summer weather, the formula could be conveniently carried into effect; at least, it would probably be found advisable to increase the proportion of wax. The weight of each suppository is about 20 grains, and the quantity of tannic acid in each 2 grains. The remedy is especially applicable to piles and prolapsus of the rectum from relaxation. W.

SUPPOSITORIA MORPHIÆ. *Br. Morphia Suppositories.*

"Take of Hydrochlorate of Morphia *three grains;* Refined Sugar *thirty grains;* Prepared Lard, White Wax, each, *a sufficiency.* Melt thirty grains of

* It has been customary to give shape to the suppository by pouring the material previously melted into small paper moulds of a conical form, which may readily be made by rolling up an oblong slip of strong glazed paper with the fingers. The hollow cones may be an inch or more in length, and about half an inch in diameter at the base. A more convenient method, however, is to cast the suppository in metallic moulds. Mr. A. B. Taylor, who has paid special attention to the subject, recommends that their shape, instead of being strictly conical, should be somewhat incurved towards the base, where there may be a small cylindrical projection for the purpose of fitting into the end of a very convenient instrument, invented by him for the introduction of the suppository into the rectum. This instrument, which he calls a *Suppositer*, consists of a slender handle a few inches long, with a ring at one end for the finger, and an expansion at the other, having a cavity for the reception of the cylindrical base of the suppository. The metallic mould should be very cold at the time of introducing the melted mixture, so as quickly to solidify it, and thus prevent the suspended medicine from sinking to the bottom, and becoming unequally distributed (*Am. Journ. of Pharm*, May, 1861, p. 202.)—*Note to the twelfth edition.*

the Lard and the same quantity of the Wax in a water bath, and, having removed the vessel, mix them thoroughly with the Hydrochlorate of Morphia and the Sugar previously rubbed together. When the mixture has solidified, divide the mass into twelve equal portions, to be formed into cones, which are to be allowed to stand till they acquire sufficient firmness. Dip each cone into a mixture of three parts of Wax and eight of Lard, melted together in a water bath, and set aside in a cool place, that the coating may become hard." *Br.*

The sugar in this mixture is probably intended to give bulk to the salt of morphia, and thereby ensure its more equable diffusion. This is an excellent remedy in strangury, tenesmus, and other cases of irritation in the lower bowels and urinary passages. It may also be used to control vomiting, and to produce the general effects of opium on the system. Each suppository contains one-fourth of a grain of muriate of morphia, and is sufficient for many of the purposes for which the medicine is given in this form, but scarcely sufficient to produce the full effects of morphia on the system in the adult. W.

SYRUPI.

Syrups.

Syrups are concentrated solutions of sugar in watery fluids, either with or without medicinal impregnation. When the solution is made with pure water, it is named *syrup* or *simple syrup*, when with water charged with one or more medicinal agents, it is called in general terms a *medicated syrup*, and receives its particular designation from the substance or substances added.

Medicated syrups are usually prepared by incorporating sugar with vegetable infusions, decoctions, expressed juices, fermented liquors, or simple aqueous solutions. When the active matter of the vegetable is not readily soluble in water, is associated with soluble matter which it is desirable to avoid, or is volatilized or decomposed by a heat of 212°, it is sometimes extracted by diluted alcohol, the spirituous ingredient of which is subsequently driven off. Medicated syrups are also occasionally prepared by adding a tincture to simple syrup, and evaporating the alcohol. Another and better mode of effecting the same object, when aromatic or other volatile substances are concerned, is to mix the tincture with sugar in coarse powder, expose the mixture to a very gentle heat or in the sun till the alcohol has evaporated, and then prepare the syrup from the impregnated sugar by dissolving it in the requisite proportion of water. Since the introduction into use of the process of percolation, or filtration by displacement, it has been applied very advantageously to the preparation of various syrups, especially those made from vegetables of which the active principle is injured or dissipated by decoction. But, unless the operator be at once skilful and careful, there will be danger of imperfectly extracting the active matters, and thus making a feeble preparation. One important practical rule is, when the liquid obtained by percolation requires concentration, to set aside the first portions of filtered liquor, which are usually strongly impregnated, and to subject only the subsequent weaker portions to evaporation. For the mode of properly conducting this process the reader is referred to *pages* 894 and 905.

The quality and quantity of the sugar employed are points of importance. Refined sugar should always be preferred, as it often saves the necessity of clarification, and makes a clearer and better flavoured syrup than the impure kinds. The U. S. Pharmacopœia simply directs sugar, but explains that it is the purified or refined sugar which is indicated by that term. In relation to the quantity of sugar, if in too small proportion, fermentation is apt to occur; if too abundant, crystallization. The proper proportion is about two parts to one of the liquid. A somewhat smaller quantity will answer, where an acid, such as lemon juice or vinegar, is used.

As it is desirable, in many instances, that the active matters should be in as concentrated a state as possible in the syrup, it is often necessary to evaporate a large proportion of the watery fluid in which they are dissolved. This may be done either before the addition of the sugar or afterwards. In either case, care is requisite not to apply a heat too great or too long continued, lest the active principles should be injured. When these are very volatile or easily decomposed by heat, it is expedient to dispense with concentration altogether. Some substances which are volatilized or decomposed at the temperature of boiling water remain fixed and unaltered at that which is necessary for the evaporation of alcohol. These, as before observed, may be dissolved in diluted alcohol, and the concentration effected by evaporating the spirituous part of the solvent. Independently of the injury which the medicinal ingredient of the syrup may sustain, the syrup itself is apt to become brown by a long-continued application of heat, even when the degree is not excessive. It is recommended, therefore, that syrups which admit of concentration should be boiled briskly over a lively fire, so as to accomplish the object as quickly as possible. It is important to be able to ascertain positively when they have attained the due consistence. An operator skilled in their preparation can judge with sufficient accuracy by various familiar signs; such as the slowness with which the parts of a drop of syrup coalesce, when previously separated by the edge of a blunt instrument; and the receding of the last portion of each drop, when the syrup, after being cooled, is poured out drop by drop. A pellicle forming upon the surface of the syrup when it cools, indicates that it has been too much boiled. But these signs are not to be relied on, except by those who have acquired much experience. The easiest method of ascertaining the proper point of concentration is by the use of that variety of Baumé's hydrometer called a *saccharometer;* an instrument almost indispensable to the apothecary. This should stand at 30° in boiling syrup (30½ in hot weather), and at 35° in the syrup when it is cool. Another very accurate, though less ready method, is to ascertain the sp. gr. by weighing a portion of the liquid. Syrup when boiling should have a sp. gr. of about 1·261; when cold, of about 1·319. Thomson and Duncan are mistaken in giving the proper sp. gr. of cold syrup as 1·385. We found that of a specimen of simple syrup, made with two pounds and a half of sugar to a pint of water, as directed in former editions of the U. S. Pharmacopœia, to be 1·326 at 68° F.; and this consistence is rather too great for practical convenience in cold weather. In the syrup now officinal it is only 1·317 at 60°, which is an improvement. A third method of ascertaining the proper point of concentration is by the thermometer, which, in boiling syrup of the proper consistence, stands at 221° F. This indication is founded on the fact, that the boiling point of syrup rises with the increase of its density.

When carefully prepared with the best double refined sugar, syrups usually require no other clarification than to remove any scum which may rise to their surface upon standing, and to pour them off from any dregs which may subside. But, as the sugar employed is seldom free from impurities, it may be best, as a general rule, to remove the scum as it rises during the heating process, and to strain them while hot through muslin or flannel. Should they at any time want the due degree of clearness, they may be filtered through flannel, or, when not likely to be injured by the treatment, may be clarified by means of the white of eggs or animal charcoal, as mentioned under the head of *Syrupus.* But the active vegetable principles are so apt to be absorbed by the charcoal along with impurities, that this agent should be used with caution.

The medicated syrups are liable to undergo various alterations, according to their nature and mode of preparation. The acid syrups, when too much boiled, often let fall a copious white deposit, which is a saccharine matter analogous to the sugar of grapes, produced by the reaction of the acid upon the sugar. Even

at ordinary temperatures, acids slowly convert common sugar into the sugar of grapes, which, being less soluble than the former, is gradually deposited in the form of crystalline grains. Syrups containing too little sugar are apt to pass into the vinous fermentation, in consequence of the presence of matters which act as a ferment. Those which contain too much deposit a portion in the crystalline state; and the crystals, attracting the sugar remaining in solution, gradually weaken the syrup, and render it liable to the same change as when originally made with too little sugar. The want of a due proportion of saccharine matter frequently also gives rise to mouldiness, when air has access to the syrup. It is said that syrups, enclosed while they are still hot in bottles, are apt to ferment; because the watery vapour, rising to the surface and there condensing, diminishes the proportion of sugar, so as to produce a commencement of chemical action, which gradually extends through the whole mass; but, if the bottles are well shaken, this result is obviated; and the syrups will generally keep better when thus treated. When syrups undergo the vinous fermentation, they become covered at the surface with froth, produced by the disengagement of carbonic acid, and acquire a vinous odour from the presence of alcohol; while their consistence is diminished by the loss of a portion of the sugar, which has been converted into that liquid. When the quantity of alcohol has increased to a certain point, the fermentation ceases, or goes on more slowly, owing to the preservative influence of that principle; and, as the active ingredient of the syrup has frequently undergone no material change, the preparation may often be recovered by boiling so as to drive off the alcohol and carbonic acid, and concentrate the liquid sufficiently. A syrup thus revived is less liable afterwards to undergo change, because the principles which acted as ferments have been diminished or consumed. It is obvious that syrups which depend for their virtues upon a volatile ingredient, or one readily changeable by heat, cannot be restored to their original condition.

At best, syrups are too apt to change, and various measures have been proposed for their preservation. According to Dr. Macculloch, the addition of a little sulphate of potassa, or chlorate of potassa which is tasteless, prevents their fermentation. M. Chereau has found sugar of milk effectual to the same end, in the instance of the syrup of poppies; and it may prove useful in others. The proportion employed by him is 32 parts of sugar of milk to 1000 of syrup. Mr. E. Durand has found that 1·3 per cent. of Hoffmann's anodyne has the effect of completely arresting or preventing fermentation, probably through the agency chiefly of the oil of wine contained in it. (*Am. Journ. of Pharm.*, xiii. 185.) But the best plan is to make small quantities of syrups at a time, and to keep them, unless when wanted for immediate use, in bottles quite full and well stopped, which should be put in the cellar or other cool place.

The Syrups, formerly officinal, which have been omitted in the present U. S. and Br. Pharmacopœias, are *Syrupus Aceti*, Ed., *Syrupus Althææ*, Lond., Ed., *Syrupus Cocci*, Lond., *Syrupus Croci*, Lond., Ed., Dub., *Syrupus Rhamni*, Lond., Ed., *Syrupus Rosæ* (*Centifoliæ*), Lond., Ed., *Syrupus Sarzæ*, Lond., Ed., and *Syrupus Violæ*, Ed. W.

SYRUPUS. *U. S.*, *Br.* Syrupus Simplex. *Syrup. Simple Syrup.*

"Take of Sugar [refined], in coarse powder, *thirty-six troyounces;* Distilled Water *a sufficient quantity.* Dissolve the Sugar, with the aid of heat, in twenty fluidounces of Distilled Water, raise the temperature to the boiling point, and strain the solution while hot. Then add sufficient Distilled Water, through the strainer, to make the Syrup measure two pints and twelve fluidounces, or weigh fifty-five troyounces. Lastly, incorporate the Water, added through the strainer, with the solution. Syrup, thus prepared, has the specific gravity 1·317." *U. S.*

"Take of Refined Sugar *five pounds* [avoirdupois]; Distilled Water *two pints* [imperial measure]. Dissolve the Sugar in the Water with the aid of heat;

and add, after cooling, as much Distilled Water as may be necessary to make the weight of the product seven pounds and a half [avoirdupois]. The sp. gr. should be 1·330." *Br.*

This syrup, when properly prepared, is inodorous, of a sweet taste without peculiar flavour, thick, viscid, nearly colourless, and perfectly transparent. If somewhat turbid, as it is apt to be when made with sugar not well refined, it may be clarified by beating the white of an egg to a froth with three or four ounces of water, mixing this with the syrup, boiling the mixture for a short time that the albumen may coagulate, and taking off the scum which rises to the surface, or separating it by filtration through paper or flannel. Two gallons of the syrup may be thus clarified. Any colour and peculiar flavour which it may possess may be removed by treating it, at the same time, with a small proportion (about 5 per cent.) of animal charcoal.

The white of egg is beaten to a froth in order that, when it coagulates, it may be rendered by the air which it contains specifically lighter than the syrup, and thus rise to the surface. If not thus treated, it floats, when coagulated, in the syrup, or sinks to the bottom. Now it is obvious that, if the syrup and albumen be heated together, the latter must be deprived of a portion of the air which it contains before the point of coagulation is attained, and thus become less disposed to rise to the surface. Guibourt, therefore, recommends that it should not be added till the syrup is boiling hot, and should then be poured in from a height, in order to increase the quantity of air entangled in it.

M. Salles, an apothecary of Clermond-Ferrand, in France, recommends that syrups which require clarification should be treated in the following manner. Allow the liquor with which the syrup is to be prepared, without previously decanting or filtering it, to become quite cold; then mix with it the white of eggs unbeaten, in the proportion of one egg for every five or six pounds (avoirdupois) of sugar employed; and, having added the sugar or honey, boil the whole for half an hour, or until a portion of the syrup upon cooling exhibits flocculi of albumen floating in a transparent medium. During the ebullition care must be taken to agitate the syrup in such a manner as to prevent the formation of foam upon its surface. When allowed to cool, the coagulated albumen with the impurities subsides, and the clear syrup floats above, and may be drawn off or decanted. In this process the albumen sinks, because not incorporated with air. M. Salles calls it clarification *per descensum*, and states that it is applicable to all syrups of a density below 30° Baumé at the boiling point. (*Journ. de Pharm.*, xxiv. 490.)

From the observations of M. Maumene, it appears that a solution of pure cane sugar, when long kept, undergoes a molecular change analogous to that produced by the reaction of weak acids; the saccharine liquid becoming brown when boiled with potassa. But, as this phenomenon is exhibited alike by uncrystallizable sugar and by glucose, the experiment does not determine which of those forms of saccharine matter has been produced. (*Comptes Rendus*, xxxix. 914.) Prof. Procter has observed a similar change in simple syrup which had been kept in his cabinet for six years. (*Am. Journ. of Pharm.*, xxvii. 430.)

Syrup is very useful in the formation of pills and mixtures, and in various other pharmaceutical operations in which sugar in solution is required.

The U. S. syrup has the sp. gr. 3·317, which is as near as may be the true standard in our climate. That of the Br. syrup is 1·330, probably adapted to the climate of Great Britain, which is not so cold in winter as ours, at least in the Northern and Middle States.

Pharm. Uses. In preparing Pilula Aloës et Myrrhæ, *U. S.;* Pil. Cambogiæ Composita, *Br.;* Pil. Galbani Comp., *U. S.;* Pil. Scillæ Comp., *U. S.*

Off. Prep. Confectio Scammonii, *Br.;* Mistura Creasoti, *Br.;* Mistura Cretæ, *Br.;* Pilulæ Ferri Carbonatis, *U.S.;* Pilulæ Ferri Compositæ, *U. S.;* Syrupus

Acidi Citrici, *U. S.;* Syrupus Aurantii, *Br.;* Syrupus Ferri Iodidi, *U. S.;* Syrupus Ipecacuanhæ, *U. S.;* Syrupus Lactucarii, *U. S.;* Syrupus Rhei, *U. S.*, Syrupus Rhei Aromaticus, *U. S.;* Syrupus Rubi, *U. S.;* Syrupus Zingiberis, *Br.* W.

SYRUPUS ACACIÆ. *U. S. Syrup of Gum Arabic.*

"Take of Gum Arabic, in pieces, *two troyounces;* Sugar [refined], in coarse powder, *fourteen troyounces;* Water *eight fluidounces.* Dissolve in the Water, first the Gum Arabic without heat, then the Sugar with a gentle heat, and strain." *U. S.*

The gum should be carefully selected; and, if its solution contain impurities, it should be strained before the addition of the sugar. On the whole, taking into consideration the great liability to the use of materials not quite pure, it might be advisable, in all cases, to heat momentarily to the boiling point, skim off what may rise to the surface, and then strain. This syrup is useful in the preparation of mixtures, pills, and troches, and is a good demulcent; but unfortunately the proportion of the gum to the sugar is too small to meet all the indications calling for the conjoint use of these two substances, and could not be much increased without endangering the stability of the preparation. W.

SYRUPUS ACIDI CITRICI. *U. S. Syrup of Citric Acid.*

"Take of Citric Acid, in fine powder, *one hundred and twenty grains;* Oil of Lemon *four minims;* Syrup *two pints.* Rub the Citric Acid and Oil of Lemon with a fluidounce of the Syrup; then add the mixture to the remainder of the Syrup, and dissolve with a gentle heat." *U. S.*

This is more uniform in its character, keeps better, and is more readily prepared than lemon syrup, but does not equal it in flavour, if the latter is well made. If long kept it is apt to acquire a musty taste, and to deposit grape sugar copiously, in consequence of the action of the acid on the cane sugar. It is much employed as an agreeable and refrigerant addition to drinks, especially carbonic acid water. Tartaric acid, on account of its greater cheapness, has not unfrequently been substituted for the citric; but the syrup made with it does not keep so well, and, moreover, is more apt to irritate the stomach.

Off. Prep. Liquor Magnesiæ Citratis, *U. S.* W.

SYRUPUS ALLII. *U. S. Syrup of Garlic.*

"Take of Garlic, sliced and bruised, *six troyounces;* Sugar [refined], in coarse powder, *twenty-four troyounces;* Diluted Acetic Acid *a pint.* Macerate the Garlic with ten fluidounces of the Diluted Acetic Acid, in a glass vessel, for four days, and express the liquid. Then mix the residue with the remainder of the Acid, and again express until sufficient additional liquid has been obtained to make the whole, when filtered, measure a pint. Lastly, introduce the Sugar into a two-pint bottle, pour upon it the filtered liquid, and agitate until it is dissolved." *U. S.*

This preparation is made upon correct principles; as vinegar is a better solvent of the active matter of garlic than water. The syrup is given in chronic catarrhal affections of the lungs, and is particularly beneficial in infantile cases, by the stimulus which it affords to the nervous system. A teaspoonful may be given for a dose to a child a year old. W.

SYRUPUS AMYGDALÆ. *U. S. Syrup of Almond. Syrup of Orgeat.*

"Take of Sweet Almond *twelve troyounces;* Bitter Almond *four troyounces;* Sugar [refined], in coarse powder, *seventy-two troyounces;* Water *three pints.* Having blanched the Almonds, rub them in a mortar to a very fine paste, adding, during the trituration, three fluidounces of the Water and twelve troyounces of the Sugar. Mix the paste thoroughly with the remainder of the Water, strain with strong expression, add to the strained liquid the remainder of the Sugar, and dissolve it with the aid of a gentle heat. Lastly, strain the solution through

muslin, and, having allowed it to cool, keep it in well-stopped bottles in a cool place." *U. S.*

This process corresponds closely with that of the French Codex. Orange-flower water, however, which is an ingredient of the French preparation, is wanting in ours. It may be added to the syrup, in the quantity of half a pint, immediately after the sugar is dissolved.

For a modified formula for preparing syrup of orgeat, by M. Capdeville, the reader is referred to the *American Journal of Pharmacy* (xxvii. 450), in which it is copied from the *Repert. de Pharm.* of January, 1855.

This is an elegant syrup, much employed in Europe, and occasionally in this country. It is demulcent, nutritive, and, in consequence of the hydrocyanic acid of the bitter almonds, somewhat sedative. It is said to impair greatly the odour of musk and assafetida, when mixed with them. It may be added to cough mixtures, or used for flavouring drinks in complaints of the chest. W.

SYRUPUS AURANTII CORTICIS. *U. S.* Syrupus Aurantii. *Br.* *Syrup of Orange Peel.*

"Take of Sweet Orange Peel, recently dried and in moderately fine powder, *two troyounces;* Carbonate of Magnesia *half a troyounce;* Sugar [refined], in coarse powder, *twenty-eight troyounces;* Alcohol, Water, each, *a sufficient quantity.* Moisten the Orange Peel with half a fluidounce of Alcohol, introduce it into a conical percolator, and pour Alcohol upon it until six fluidounces of tincture have passed. Evaporate this, at a temperature not exceeding 120°, to two fluidounces, add the Carbonate of Magnesia and a troyounce of the Sugar, and rub them together, gradually adding half a pint of Water during the trituration. Then filter, and having added sufficient Water to make the liquid measure a pint, dissolve in it the remainder of the Sugar with the aid of a gentle heat, and strain." *U. S.*

"Take of Tincture of Orange Peel *one fluidounce;* Syrup *seven fluidounces.* Mix." *Br.*

The present U. S. formula is a great improvement over that of 1850, in which water was used as the menstruum, and consequently but little relatively of the volatile oil of the resin was extracted. Not only is alcohol used, but afterwards, when, the greater part of the alcohol having been evaporated as no longer needed, water is added, care is taken, by rubbing this and the concentrated tincture with carbonate of magnesia, to enable the water to take up and hold in solution the oil extracted by the alcohol. The present syrup is consequently much more highly flavoured than the one which it has superseded. In the evaporation it is important that the heat should not exceed 120°, in consequence of the volatile nature of the active principle of the peel; and, to facilitate the solution of the sugar, it should be previously powdered. The British preparation, which is a mere mixture of the tincture with syrup, is in all respects inferior. The U. S. formula is that of Prof. Procter, which was published in the eleventh edition of the U. S. Dispensatory (*page* 1274). The use of carbonate of magnesia was first suggested by Mr. John D. Finley.

The syrup has an agreeable flavour, for which alone it is employed. Prepared according to the U. S. process of 1850, it was apt to ferment in warm weather; an objection to which the present syrup is not liable.

Off. Prep. Confectio Sulphuris, *Br.* W.

SYRUPUS AURANTII FLORUM. *U. S.* Syrupus Aurantii Floris. *Br.* *Syrup of Orange Flowers.*

"Take of Orange Flower Water *five fluidounces;* Sugar [refined], in coarse powder, *thirty-six troyounces;* Distilled Water *fifteen fluidounces.* Dissolve the Sugar in the Distilled Water, with the aid of a gentle heat, and raise the

temperature to the boiling point. When the solution is nearly cold, mix thoroughly with it the Orange Flower Water, and strain." *U. S.*

"Take of Orange-flower Water *eight fluidounces;* Refined Sugar *three pounds* [avoirdupois]; Distilled Water *sixteen fluidounces,* or *a sufficiency.* Dissolve the Sugar in the Distilled Water, by means of heat; strain, and when nearly cold add the Orange-flower Water, with a sufficient quantity of Distilled Water, if necessary, to make the product four pounds and a half [avoird.]. The sp. gr. should be 1·330." *Br.*

This is used for flavouring mixtures. W.

SYRUPUS FERRI IODIDI. *U. S.*, *Br.* Liquor Ferri Iodidi. *U. S.* 1850. *Syrup of Iodide of Iron. Solution of Iodide of Iron.*

"Take of Iodine *two troyounces;* Iron, in the form of wire and cut in pieces, *three hundred grains;* Distilled Water *three fluidounces;* Syrup *a sufficient quantity.* Mix the Iodine, Iron, and Distilled Water in a flask of thin glass, shake the mixture occasionally until the reaction ceases, and the solution has acquired a green colour and lost the smell of iodine. Then, having introduced a pint of Syrup into a graduated bottle, heat it by means of a water-bath to 212°, and, through a small funnel inserted in the mouth of the bottle, filter into it the solution already prepared. When this has passed, close the bottle, shake it thoroughly, and, when the liquid has cooled, add sufficient Syrup to make the whole measure twenty fluidounces. Lastly, again shake the bottle, and transfer its contents to two-ounce vials, which must be well stopped." *U. S.*

"Take of fine Iron Wire *one ounce* [avoirdupois]; Iodine *two ounces* [avoird.]; Refined Sugar *twenty-eight ounces* [avoird.]; Distilled Water *thirteen fluidounces.* Prepare a syrup by dissolving the Sugar in ten [fluid]ounces of the Water with the aid of heat. Digest the Iodine and the Iron Wire in a flask, at a gentle heat, with the remaining three [fluid]ounces of the Water, till the froth becomes white; then filter the liquid, while still hot, into the syrup, and mix. The product should weigh two pounds eleven ounces [avoird.], and should have the sp. gr. 1·385." *Br.*

These preparations furnish solutions of iodide of iron, rendered more permanent by sugar. The mode of making the iodide is precisely the same as that given under the head of *Ferri Iodidum.* The gentle heat employed in the British process is unnecessary. The iodine should be quite dry; as, if moist, as British iodine often is, less iodide of iron will be formed, and the syrup will be proportionably weaker. In both processes a large excess of iron is taken, being greatest in the British. A moderate excess is useful in preventing the solution of iodide of iron from undergoing any change from the absorption of oxygen during filtration, before it comes in contact with the sugar. Assuming that the iodine without loss is all converted into iodide of iron, it is easy to calculate the strength of the officinal solutions. Thus, it will be found that the U. S. solution contains 7·33 grains, and that of the British Pharmacopœia about 4·30 grains of the dry iodide to the fluidrachm. In both preparations there is sufficient sugar to constitute a syrup; the present U. S. process differing in this respect from that of 1850, which was denominated a solution, because containing insufficient sugar to be entitled to the name of a syrup. Indeed, the proportion of sugar in the old formula was insufficient duly to protect the iodide, and was therefore increased. In the solution of 1850, a coil of iron wire, or a strip of bright iron, immersed in the solution, was found to assist in preserving it from change.

The plan of protecting the solution of iodide of iron from change by saccharine matter originated with M. Frederking, of Riga, who published a formula for the purpose in *Buchner's Repertorium* in 1839. The same plan was proposed in a paper by Prof. Procter, contained in the *Amer. Journ. of Pharmacy* for April, 1840. In the *Journal de Pharmacie* for March, 1841, Dr. Dupasquier, of Lyons, claims to have made a pure iodide of iron, protected by syrup of gum,

as early as 1838. In the *Pharm. Journ.* for August, 1841, the late Dr. A. T. Thomson published a paper in which he confirmed the results of Frederking and Procter, and proposed a formula for a *strong syrup*, which is the basis of that adopted in the British Pharmacopœia.

Properties. The *U. S. syrup of iodide of iron* is a transparent liquid, of a pale-green colour, and deposits no sediment on being kept; nor does it tinge a solution of starch blue, showing that it is well protected. In regard to the former U. S. preparation, Mr. E. S. Wayne observed that, when kept for some time, it occasionally deposited grape sugar, into which the cane sugar was converted, probably through the agency of hydriodic acid. According to Mr. J. M. Maisch, of this city, the solution was decomposed not only by light, but also by the action of atmospheric oxygen in bottles partly filled and frequently opened. The oxidation of the iron and the evolution of the iodine were accelerated by the action of light, when the solution was thus insecurely kept; but, when the altered solution was transferred to air-tight bottles, completely filled, and exposed to the direct light of the sun, it resumed its transparency; and its original colour was restored, or rendered much lighter. After this restoration the solution could not be the same; and Mr. Maisch thought it probable that it contained some iodate of sesquioxide of iron. (See his papers in the *Am. Journ. of Pharm.* for Sept. 1854, and May, 1855.) The removal of the apparent defects of a solution of iodide of iron by the action of sunlight is, therefore, not an admissible expedient; because it changes the nature of the solution. Mr. Maisch discovered copper in a sample of this preparation. It may be detected by putting into the solution a piece of bright iron, which, by a prolonged contact, will be covered with copper, if that metal be present. Syrup of iodide of iron is rendered brown by sulphuric acid, and emits violet vapours when heated. It should not contain any free iodine, which, if present, may be detected by the production of a blue colour with starch.

These observations of Mr. Maisch in reference to the former Liquor Ferri Iodidi, so far as concerns the influence of light, are probably true of the present syrup, though the greater proportion of sugar contained gives it, no doubt, additional protection against the oxidizing influence of the air.

When the syrup is concentrated it becomes brown, and, when evaporated to dryness, forms a mass which may be called *saccharine iodide of iron*, and which is not entirely soluble again, a little sesquioxide of iron being left. This saccharine iodide, being protected by the sugar it contains, is not liable to the objections which apply to the pure solid salt, and may be made into pills.

Medical Properties. These have been detailed under the head of *Ferri Iodidum.* The dose of the syrup is from 20 to 40 minims, diluted with water. The dilution should be made at the moment it is taken; and, in order to guard against injury to the teeth, the mouth should be carefully washed after each dose.

Solution of iodide of iron is sometimes used as an external application; and when so employed, the necessary dilution should be made at the moment of applying it. B.

SYRUPUS FERRI PHOSPHATIS. *Br. Syrup of Phosphate of Iron.*

"Take of Granulated Sulphate of Iron *two hundred and twenty-four grains;* Phosphate of Soda *two hundred grains;* Acetate of Soda *seventy-four grains;* Diluted Phosphoric Acid *five fluidounces and a half;* Refined Sugar *eight ounces* [avoirdupois]; Distilled Water *eight fluidounces.* Dissolve the Sulphate of Iron in four [fluid]ounces of the Water, and the Phosphate and Acetate of Soda in the remainder; mix the two solutions, and, after careful stirring, transfer the precipitate to a calico filter, and wash it with Distilled Water, till the filtrate ceases to be affected by chloride of barium. Then press the precipitate strongly between folds of bibulous paper, and add to it the Dilute Phosphoric Acid. As soon as the precipitate is dissolved, filter the solution, add the

Sugar, and dissolve without heat. The product should measure exactly twelve fluidounces." *Br.*

The first part of this process is almost precisely a repetition of that of the Br. Pharmacopœia for phosphate of iron. (See *Ferri Phosphas.*) But after that salt has been prepared, instead of being dried, it is first strongly pressed, and then dissolved in the dilute phosphoric acid, and made into a syrup with sugar. As the phosphate of iron is insoluble in water, it was necessary to have recourse to an acid to effect its solution, and the phosphoric acid was selected as therapeutically co-indicated. Each fluidrachm contains 3·5 grains of the phosphate of iron, and about 27·5 minims of dilute phosphoric acid. For its properties and uses, see *Ferri Phosphas* (page 1143). The dose is one or two fluidrachms. W.

SYRUPUS HEMIDESMI. *Br. Syrup of Hemidesmus. Syrup of Indian Sarsaparilla.*

"Take of Hemidesmus, bruised, *four ounces* [avoirdupois]; Refined Sugar *twenty-eight ounces* [avoird.]; Boiling Distilled Water *one pint* [Imperial measure]. Infuse the Hemidesmus in the Water, in a covered vessel, for four hours, and strain. Set it by till the sediment subsides; then decant the clear liquor, add the Sugar, and dissolve by means of a gentle heat. The product should weigh two pounds ten ounces, and should have the specific gravity 1·335."

This is a very weak preparation. The dose is stated at from one to four fluidrachms, but the syrup may be taken almost ad libitum. (See *Hemidesmus.*) W.

SYRUPUS IPECACUANHÆ. *U. S. Syrup of Ipecacuanha.*

"Take of Fluid Extract of Ipecacuanha *two fluidounces;* Syrup *thirty fluidounces.* Mix them." *U. S.*

By the former U. S. process of 1850, a tincture of ipecacuanha was first formed with diluted alcohol, then reduced by evaporation so as to drive off the alcohol, and afterwards diluted with water and made into a syrup with sugar. The present process simply mixes the fluid extract, which is an officinal preparation, with syrup. The French Codex dissolves the alcoholic extract of ipecacuanha in water, and then mixes it with syrup; but it is obvious that the U. S. plan is preferable, as it spares the continued heat requisite to reduce the tincture to dryness. The present U. S. syrup, which is twice as strong as that of 1850, is made in accordance with the suggestions of Mr. Laidley, of Richmond, Va., who found the syrup, as ordinarily prepared, to spoil by keeping. (*Am. Journ. of Pharm.*, xxvi. 103.)

This syrup is chiefly applicable to the cases of children. One fluidounce of it, prepared according to the U. S. formula, should contain the virtues of thirty grains of ipecacuanha. The dose of it, as an emetic, is for an adult from four fluidrachms to a fluidounce, for a child a year or two old, from thirty minims to a fluidrachm, repeated every fifteen or twenty minutes till it acts. As an expectorant, the dose for an adult is thirty minims or a fluidrachm, for a child from two to ten minims. W.

SYRUPUS KRAMERIÆ. *U. S. Syrup of Rhatany.*

"Take of Rhatany, in moderately fine powder, *twelve troyounces;* Sugar [refined], in coarse powder, *thirty troyounces;* Water *a sufficient quantity.* Mix the Rhatany with half a pint of Water, and, having allowed the mixture to stand for two hours, introduce it into a glass percolator, and gradually pour Water upon it until four pints of filtered liquor are obtained. Evaporate this, by means of a water-bath, to seventeen fluidounces, and, having added the Sugar, dissolve it with the aid of a gentle heat, and strain the solution while hot. This Syrup may also be prepared in the following manner.

"Take of Extract of Rhatany *two troyounces;* Sugar in coarse powder, *thirty*

troyounces; Water *a pint.* Dissolve the Extract in the Water, and filter; then, having added the Sugar, dissolve it with the aid of a gentle heat, and strain the solution while hot." *U. S.*

As rhatany yields a variable proportion of extract, it follows that the syrup resulting from these two modes of preparation must differ. To obviate this evil as far as possible, care should be taken, in following the first process, to select the best rhatany, and preferably the small roots, as it is these only which will yield two ounces of good extract to the pound.

In the second process, extract of rhatany as free as possible from insoluble matter should be chosen; and that prepared according to the U. S. directions will be found the best. (See *Extractum Krameriæ.*) This preparation affords a convenient mode of exhibiting rhatany to infants. The dose for an adult is half a fluidounce, for a child a year or two old, twenty or thirty minims. W.

SYRUPUS LACTUCARII. *U. S. Syrup of Lactucarium.*

"Take of Lactucarium *a troyounce;* Syrup *fourteen fluidounces;* Diluted Alcohol *a sufficient quantity.* Rub the Lactucarium with sufficient Diluted Alcohol, gradually added, to bring it to a syrupy consistence. Then introduce it into a conical percolator, and, having carefully covered the surface with a piece of muslin, gradually pour Diluted Alcohol upon it until half a pint of tincture has passed. Evaporate this, by means of a water-bath, at a temperature not exceeding 160°, to two fluidounces, mix it with the Syrup, previously heated, and strain while hot." *U. S.*

This syrup has the virtues of lactucarium, free from its inert albuminous matter. The dose of it is two or three fluidrachms. W.

SYRUPUS LIMONIS. *U. S., Br. Syrup of Lemon.*

"Take of Lemon Juice, recently expressed and strained, *a pint;* Sugar [refined], in coarse powder, *forty-eight troyounces;* Water *a pint.* Mix the Lemon Juice and Water, and, having added the Sugar to the mixture, dissolve it with the aid of a gentle heat, and strain the solution while hot." *U. S.*

"Take of Fresh Lemon Peel *two ounces* [avoirdupois]; Lemon Juice, strained, *one pint* [Imperial measure]; Refined Sugar *two pounds and a quarter* [avoird.]. Add the Sugar and the Lemon Peel to the Lemon Juice in a covered vessel, and dissolve the Sugar with the aid of a steam or water bath, then strain. The product should weigh three pounds and a half [avoird.], and should have the sp. gr. 1·340." *Br.*

The British preparation has an advantage over that of the U. S. Pharmacopœia in possessing more of the aromatic flavour of the rind; and it would be an improvement to our formula to add a little grated fresh lemon-peel to the other ingredients. In the present U. S. syrup, the juice, instead of being used undiluted, as in the process of 1850, is mixed with an equal measure of water, which is an improvement.

This syrup forms a cooling and grateful addition to beverages in febrile complaints, and serves to conceal the taste of saline purgatives in solution. W.

SYRUPUS MORI. *Br. Syrup of Mulberries.*

"Take of Mulberry Juice *one pint* [Imperial measure]; Refined Sugar *two pounds* [avoirdupois]; Rectified Spirit *two fluidounces and a half.* Dissolve the Sugar in the Juice, by a gentle heat, and set aside for twenty-four hours. Then remove the scum, and pour off the clear liquid from the dregs, if any appear. Lastly, add the Spirit. The product should weigh three pounds six ounces [avoird.], and should have the sp. gr. 1·330." *Br.*

This may be used for the same purposes with lemon syrup. In like manner syrups may be prepared from various succulent fruits, such as *strawberries, raspberries, blackberries, currants, pineapples,* &c. When the juice is thick, it may be diluted with from one-third of its bulk to an equal bulk of water pre-

viously to the addition of the sugar. In the preparation of *raspberry syrup*, which, as ordinarily made, is apt to gelatinize, M. Blondeau recommends that the strained juice be allowed to stand from eight to fifteen hours, according to the temperature, in order to ferment. The juice separates into two portions, the upper thick, the lower clear. The latter is to be separated by straining, and made into a syrup with the usual proportion of sugar. The process of the London College for Syrupus Mori, retained in the British Pharmacopœia, is in accordance with this recommendation. These syrups are employed to flavour drinks, and are much used as grateful additions to carbonic acid water.* W.

SYRUPUS PAPAVERIS. *Br. Syrup of Poppies.*

"Take of Poppy Capsules, bruised and freed from seed, *thirty-six ounces* [avoirdupois]; Boiling Distilled Water *twenty pints* [Imperial measure]; Rectified Spirit *sixteen fluidounces;* Refined Sugar *four pounds* [avoird.]. Macerate the Poppy Capsules in the Water, in a water bath, kept hot, for twelve hours. Then evaporate all the water except that absorbed by the capsules, press strongly, and strain. Reduce the strained liquor to three pints [Imp. meas.], and, when quite cold, add the Spirit. Mix and filter. Distil off the spirit, evaporate the remaining liquor to two pints [Imp. meas.], and then add the Sugar. The product should weigh six pounds and a half [avoird.], and should have the sp. gr. 1·320."

As the capsules contain variable proportions of the narcotic principle, the syrup prepared from them is necessarily of variable strength. It was, moreover, as formerly prepared, very apt to spoil. It is, we presume, to correct this tendency, that the direction is given in the Pharmacopœia to add alcohol to the infusion, by which coagulable matter may be separated; the alcohol itself being

* Some practical remarks in relation to these syrups, so much used with artificial mineral water, may prove useful to the inexperienced pharmaceutist. Care should be taken that the fruit employed should be fully ripe, and freed from all its natural attachments, as calyx, stem, &c., and from all other impurities. Without being previously crushed, it should be put into canvass or woollen bags, which should be about two-thirds full when placed under the press. The expressing force should be gradually increased, so as effectually to remove the juice with as little of the tissue of the fruit as possible. It is customary to make a pint of syrup from a pint measure of fruit, and, if the expressed juice is insufficient for the purpose, to dilute it with water; but this is obviously an arbitrary rule, which cannot be universally applied without injuriously affecting the character of the product. The rule in the text is better; viz., to dilute the juice when too thick. In dissolving the sugar, as short an exposure to heat as possible is desirable. Some dissolve the sugar in a portion of the juice with heat, and add the remainder a few minutes before removal from the fire. Some fruits contain so much pectin that their syrups are apt to gelatinize. This is particularly the case with currants and raspberries. A mode of preventing this result has been mentioned in the text. Another method is to add to the juice, after expression, one-tenth of its bulk of the juice of sour cherries, allow the mixture to stand for fifteen hours, and then separate the coagulated pectin by very gentle pressure in a cloth. *Pineapple* syrup may be made either in the ordinary mode, or by slicing the fruit, alternating the slices with layers of powdered sugar, permitting them to stand twenty-four hours, and then expressing the syrup formed. Each pound of the pared fruit, with thirty ounces of sugar, should yield with the requisite quantity of water two pints of syrup. For some further practical remarks on the preparation of particular syrups, the reader is referred to a paper by Mr. Ambrose Smith, in the *American Journal of Pharmacy* (xxii. 212).

Cream Syrups. Under this name, there has come into use, in Philadelphia, a variety of syrups, given with carbonic acid water, to which they impart an agreeable richness of flavour. To prepare them, a gallon of fresh sweet cream is made to dissolve, without heat, 14 pounds (avoird.) of powdered sugar; and the solution, having been immediately bottled, is placed on ice, in a cold cellar. It will keep from three to eight days, according to circumstances. It is added to other syrups, given with carbonic acid water, equal measures being employed. The use of cream syrups is said to have originated with Mr. C. A. Smith, of Cincinnati. Mr. A. B. Taylor, of Philadelphia, prepares *cream vanilla syrup* by mixing together three fluidrachms of strong fluid extract of vanilla, a pint of simple syrup, and a pint of cream syrup. (*Am. Journ. of Pharm.*, xxvii. 407.)—*Notes to the ninth and eleventh editions.*

subsequently removed by distillation. The place, however, of this syrup, might, with great propriety, be supplied by a syrup prepared from one of the salts of morphia, which would keep well, and have the advantage of uniform strength. Four grains of the sulphate of morphia dissolved in a pint of syrup, would afford a preparation at least equal to the average strength of the syrup of poppies, and much more certain in its operation. Mr. Southall recommends that the syrup of poppies should be prepared with a cold infusion made by percolation; the same proportions being employed as directed by the late London Pharmacopœia. The virtues of the capsules are thus extracted without those principles which cause the syrup to ferment speedily. (See *Am. Journ. of Pharm.*, xv. 140.) Mr. Southall, after preparing the infusion, evaporates it to the proper measure before adding the sugar. Mr. Stocken prefers adding the sugar before the concentration is completed, and afterwards evaporating to 32° of the saccharometer. (*Pharm. Journ.*, xi. 299.) It is probable that a syrup, prepared with diluted alcohol as the menstruum, would keep better than that made on either of the above plans.*

The syrup of poppies is employed, chiefly in infantile cases, to allay cough, quiet restlessness, relieve pain, and promote sleep. The dose is from half a fluidrachm to a fluidrachm for an infant, from half a fluidounce to a fluidounce for an adult. W.

SYRUPUS PRUNI VIRGINIANÆ. *U. S.* *Syrup of Wild-cherry Bark.*

"Take of Wild-cherry Bark, in coarse powder, *five troyounces;* Sugar [refined], in coarse powder, *twenty-eight troyounces;* Water *a sufficient quantity.* Moisten the Bark thoroughly with Water, and allow it to stand for twenty-four hours in a close vessel; then pack it firmly in a glass percolator, and gradually pour Water upon it until a pint of filtered liquor is obtained. To this, transferred to a bottle, add the Sugar, and agitate occasionally until it is dissolved." *U. S.*

This process affords a handsome syrup, with the virtues of the bark unimpaired by the injurious effects of heat. It is based upon a formula proposed by Messrs. Procter and Turnpenny in the *American Journal of Pharmacy* (xiv. 27). It probably more precisely represents the bark than is done by the fluid extract, which contains a smaller proportion of the tannic acid than the bark, in consequence of the removal of a part of that principle by combination with the albumen of the almonds used in the process. In some cases, this want of tannic acid may specially recommend the fluid extract; while in others, as in the diarrhœa of phthisis, for example, the syrup or infusion might be preferable from retaining it. The dose is half a fluidounce. W.

SYRUPUS RHEI. *U. S.* *Syrup of Rhubarb.*

"Take of Fluid Extract of Rhubarb *three fluidounces;* Syrup *twenty-nine fluidounces.* Mix them thoroughly." *U. S.*

This formula is an improvement on that of 1850, as being more precise. The syrup is a mild cathartic, adapted to the cases of infants, to whom it may be given in the dose of a fluidrachm. W.

SYRUPUS RHEI AROMATICUS. *U. S.* *Aromatic Syrup of Rhubarb.*

* Prof. Procter has furnished us with the following formula, which he has used for many years, and found to yield a good syrup, that will keep well. "Take of Poppy Capsules, deprived of their seeds, and ground into coarse powder, *eight troyounces;* Sugar *fifteen troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with four fluidounces of the Diluted Alcohol, pack it firmly in a percolator, and pour Diluted Alcohol upon it until three pints have slowly passed. Distil off the alcohol until the residual liquid is reduced to half a pint, and filter. Allow sufficient Distilled Water to pass through the filter to make the filtrate measure half a pint; then add the Sugar, dissolve with heat, and strain."—*Note to the twelfth edition.*

"Take of Rhubarb, in moderately fine powder, *two troyounces and a half;* Cloves, in moderately fine powder, Cinnamon, in fine powder, each, *half a troyounce;* Nutmeg, in moderately fine powder, *one hundred and twenty grains;* Syrup *six pints;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with two fluidounces of Diluted Alcohol, introduce it into a conical percolator, and pour Diluted Alcohol upon it until a pint of tincture has passed. Add this to the Syrup, previously heated, and mix them thoroughly." *U. S.**

The aromatic syrup of rhubarb is a warm stomachic laxative, too feeble for adult cases, but well calculated for the bowel-complaints of infants which are so frequent in our cities during the summer season, and as a remedy for which this preparation, or one analogous to it, has been long in use under the name of *spiced syrup of rhubarb.* The dose for an infant with diarrhœa is a fluidrachm, repeated every two hours till the passages indicate by their colour that the medicine has operated. It should be borne in mind that the syrup, as prepared by the present formula, contains one-seventh of diluted alcohol, which, though not injurious in most of the cases in which this syrup is used, might render it too stimulant in some instances of diarrhœa in the very young infant. W.

SYRUPUS RHŒADOS. *Br. Syrup of Red Poppy.*

"Take of Red-poppy Petals *thirteen ounces* [avoirdupois]; Refined Sugar *two pounds and a quarter* [avoird.]; Distilled Water *one pint* [Imperial measure], or *a sufficiency;* Rectified Spirit *two fluidounces and a half.* Add the Petals gradually to the Water heated in a water-bath, frequently stirring, and afterwards, the vessel being removed, macerate for twelve hours. Then press out the liquor, strain, add the Sugar, and dissolve by means of heat. When nearly cold, add the Spirit, and as much Distilled Water as may be necessary to make up for loss in the process, so that the product shall weigh three pounds ten ounces, and should have the sp. gr. 1·330." *Br.*

The object of introducing the petals into water heated by a water-bath is that they may shrink by being scalded; as otherwise they could not be completely immersed in the quantity of water directed. After this has been accomplished, they should be immediately removed from the fire, lest the liquor become too thick and ropy. The fine red colour of this syrup is its only recommendation. It is very liable to ferment. W.

SYRUPUS ROSÆ GALLICÆ. *U. S., Br. Syrup of Red Rose.*

"Take of Red Rose, in moderately fine powder, *two troyounces;* Sugar [refined], in coarse powder, *eighteen troyounces;* Diluted Alcohol, Water, each, *a sufficient quantity.* Moisten the Rose with Diluted Alcohol, pack it firmly in a conical glass percolator, and gradually pour Diluted Alcohol upon it until a fluidounce of tincture has passed. Set this aside, and continue the percolation until five fluidounces more of tincture are obtained. Evaporate this with a gentle heat to a fluidounce and a half, and mix it with seven fluidounces of Water. Then, having added the Sugar, dissolve it with the aid of a gentle heat, and strain the solution while hot. Lastly, when the solution is cold, add the fluidounce of reserved tincture, and mix them thoroughly." *U. S.*

"Take of dried Red-rose Petals *two ounces* [avoirdupois]; Refined Sugar *thirty ounces* [avoird.]; Boiling Distilled Water *one pint* [Imperial mea-

* The following is the preferred formula of the Pharmacopœia of 1850, omitted in the present edition, in which the syrup is prepared by maceration. "Take of Rhubarb, bruised, *two ounces and a half;* Cloves, bruised, Cinnamon, bruised, each, *half an ounce;* Nutmeg, bruised, *two drachms;* Diluted Alcohol *two pints;* Syrup *six pints.* Macerate the Rhubarb and Aromatics in the Diluted Alcohol for fourteen days, and strain; then, by means of a water-bath, evaporate the liquor to a pint, and, while it is still hot, mix it with the Syrup previously heated." Care should be taken, in evaporating the tincture, not to let the heat exceed that of a water-bath, lest the aromatic oils should be driven off.

sure]. Infuse the Petals in the Water for two hours, squeeze through calico, and filter. Dissolve the Sugar in the liquor by means of heat. The product should weigh two pounds fourteen ounces [avoird.], and should have the sp. gr. 1·335." *Br.*

The syrup of red roses is mildly astringent; but is valued more for its fine red colour, on account of which it is occasionally added to mixtures. W.

SYRUPUS RUBI. *U. S. Syrup of Blackberry Root.*

"Take of Blackberry Root, in moderately fine powder, *eight troyounces;* Syrup *a pint and a half;* Diluted Alcohol *a sufficient quantity.* Introduce the powder, previously moistened with *four fluidounces* of Diluted Alcohol, into a glass percolator, and pour Diluted Alcohol upon it until a pint and a half of tincture have passed. Evaporate this, by means of a water-bath, at a temperature not exceeding 160°, to half a pint; then mix it while hot with the Syrup previously heated, and strain." *U. S.*

This process might perhaps be improved by filtering the concentrated tincture before the addition of the sugar. The Syrup is a new officinal of the U. S. Pharmacopœia, called for by the popularity of similar preparations. It is very useful in diarrhœa of relaxation, and in the chronic forms of that complaint. The dose is one or two fluidrachms. W.

SYRUPUS SARSAPARILLÆ COMPOSITUS. *U. S. Compound Syrup of Sarsaparilla.*

"Take of Sarsaparilla, in moderately coarse powder, *twenty-four troyounces;* Guaiacum Wood, in moderately coarse powder, *three troyounces;* Pale Rose, in moderately coarse powder, Senna, in moderately coarse powder, Liquorice Root, in moderately coarse powder, each, *two troyounces;* Oil of Sassafras, Oil of Anise, each, *five minims;* Oil of Gaultheria *three minims;* Sugar, in coarse powder, *ninety-six troyounces;* Diluted Alcohol *a sufficient quantity.* Mix the solid ingredients, except the Sugar, with three pints of Diluted Alcohol, and allow the mixture to stand for twenty-four hours; then transfer it to a cylindrical percolator, and gradually pour Diluted Alcohol upon it until ten pints of tincture have passed. Evaporate this, by means of a water-bath, to four pints, filter, and, having added the Sugar, dissolve it with the aid of heat, and strain the solution while hot. Lastly, rub the Oils with a small portion of the solution, and mix them thoroughly with the remainder." *U. S.*

In the original edition of the U. S. Pharmacopœia published in 1820, a process for a syrup of sarsaparilla was adopted, intended to represent the famous French *sirop de Cuisinier.* This was very much improved in the revised edition published in 1830; and the amended process has been retained with little alteration in the subsequent editions; the process of percolation having been substituted in the present Pharmacopœia for simple maceration directed in the first of the two formulas of 1850. In the original process, the sarsaparilla was subjected to long decoction with water. Now it has been proved that diluted alcohol more thoroughly extracts the acrid principle of the root, upon which its activity probably depends, than water, and that this principle is either dissipated or destroyed by the long-continued application of a boiling heat.* In the present formula, therefore, which employs diluted alcohol as the menstruum, the root is more completely exhausted of its active matter; while the heat applied to the concentration, being no higher than is requisite for the evaporation of the alcohol, is insufficient to injure the preparation. The spirituous menstruum has, moreover, the advantage of not dissolving the inert fecula, which encumbers

* See a paper by J. Hancock, M. D., republished in the *Journal of the Philadelphia College of Pharmacy* (i. 295); a communication by M. Béral to the *Journal de Pharmacie* (xv. 657); another by M. Soubeiran in the same journal (xvi. 38); and a paper by T. J. Husband in the *American Journal of Pharmacy* (xv. 6).

the syrup prepared by decoction, and renders it liable to spoil. In the Pharmacopœia of 1840, the pale or hundred-leaved roses were very properly substituted for the red; as their slightly laxative property accords better with the character of the preparation. The operator should be careful to comply exactly with the directions of the Pharmacopœia, not only those of the present formula, including the use of the water-bath, but also the general rules given for the management of the process of percolation. The essential oils, being intended solely to communicate an agreeable flavour, are used in very small proportion. The only objection to this process is that a portion of the resin, extracted by the alcohol from the guaiacum wood, is deposited during the evaporation of the tincture; but this is separated by the filtration directed, and is therefore of no disadvantage to the preparation. But the practitioner should be aware that much of the sarsaparilla, as it exists in the market, is nearly or quite inert, and should be prepared to meet with disappointment in the use of this or any other preparation, unless satisfied of the good quality of the drug from which it is made.

Corrosive sublimate, which is often given in connection with this syrup, is said to be completely decomposed by it, being converted into calomel. M. Lepage, of Gisors, proposes as a substitute the iodohydrargyrate of potassium (see *Part III.*), which he has found not to undergo decomposition. (*Journ. de Pharm.*, 3*e sér.*, viii. 63.)

The dose of the syrup is half a fluidounce, equivalent to somewhat less than a drachm of the root, to be taken three or four times a day. W.

SYRUPUS SCILLÆ. *U. S.*, *Br. Syrup of Squill.*

"Take of Vinegar of Squill *a pint;* Sugar [refined], in coarse powder, *twenty-four troyounces.* Dissolve the Sugar in the Vinegar of Squill, with the aid of a gentle heat, and strain the solution while hot." *U. S.*

"Take of Squill, bruised, *two ounces and a half* [avoirdupois]; Dilute Acetic Acid *one pint* [Imperial measure]; Refined Sugar *two pounds* [avoird.]; Proof Spirit *one fluidounce and a half.* Digest the Squill in the Dilute Acetic Acid for three days, with a gentle heat; express, add the Spirit, and filter; then mix in the Sugar, and dissolve with the aid of heat. The product should weigh three pounds two ounces [avoird.], and should have the sp. gr. 1·330." *Br.*

This syrup is much employed as an expectorant, especially in combination with a solution of tartarized antimony. The dose is about a fluidrachm. In infantile cases of catarrh and other pectoral complaints, it is sometimes given, in the same dose, as an emetic. W.

SYRUPUS SCILLÆ COMPOSITUS. *U.S. Compound Syrup of Squill. Hive Syrup.*

"Take of Squill, in moderately coarse powder, Seneka, in moderately fine powder, each, *four troyounces;* Tartrate of Antimony and Potassa *forty-eight grains;* Sugar [refined], in coarse powder, *forty-two troyounces;* Diluted Alcohol, Water, each, *a sufficient quantity.* Mix the Squill and Seneka, and, having moistened the mixture with half a pint of Diluted Alcohol, allow it to stand for an hour. Then transfer it to a conical percolator, and pour Diluted Alcohol upon it until three pints of tincture have passed. Boil this for a few minutes, evaporate it by means of a water-bath to a pint, add six fluidounces of boiling Water, and filter. Dissolve the Sugar in the filtered liquid, and, having heated the solution to the boiling point, strain it while hot. Then dissolve the Tartrate of Antimony and Potassa in the solution while still hot, and add sufficient boiling Water, through the strainer, to make it measure three pints. Lastly, mix the whole thoroughly together." *U. S.*

This is intended as a substitute for the popular preparation called *Coxe's hive-syrup*, from which it differs chiefly in containing sugar instead of honey. Prepared as originally directed in the Pharmacopœia, it invariably fermented

from the want of sufficient concentration. This defect was corrected at the revision of 1840, when also sugar was substituted for honey, in consequence of the uncertain consistence and constitution of the latter. In the Pharmacopœia of 1850 two formulas were given for this syrup; in the first of which the virtues of the squill and seneka were extracted by long boiling with water, in the second, by percolation with water to which a small portion of alcohol was added. The latter was preferable when skilfully performed; as it avoided in great measure the injurious influence of boiling upon the seneka, exhausted both this and the squill more readily in consequence of the addition of alcohol to the menstruum, and afforded a solution of their active principles, less embarrassed with inert matters calculated to favour fermentation. In this process, the filtered liquor was raised to the boiling point in order to coagulate the albumen, after which the evaporation was conducted at a lower temperature. The present formula is a decided improvement upon the one just described; as, diluted alcohol being employed as the menstruum, less of the albuminous and mucilaginous matter is extracted; while any disadvantage from the spirituous addition is obviated by the subsequent evaporation of the alcohol and the addition of water; the provision being retained to boil the tincture for a short time to get rid of any albumen that may have been taken up.*

The compound syrup of squill combines the virtues of seneka, squill, and tartar emetic, of the last of which it contains one grain in every fluidounce. It is emetic, diaphoretic, expectorant, and frequently cathartic, and may be given with advantage in mild cases of croup, in the latter stages of severe cases when the object is to promote expectoration, and in other pectoral affections in which the same indication is presented. As an emetic, however, in croup, we prefer a simple solution of tartar emetic in water. The dose of this syrup is, for children, from ten drops to a fluidrachm, according to the age, and should be repeated in cases of croup every fifteen or twenty minutes till it vomits. As an expectorant for adults the dose is twenty or thirty drops. W.

SYRUPUS SENEGÆ. *U. S. Syrup of Seneka.*

"Take of Seneka, in moderately fine powder, *four troyounces:* Sugar [refined], in coarse powder, *fifteen troyounces;* Diluted Alcohol *two pints.* Moisten the Seneka with two fluidounces of the Diluted Alcohol; then transfer it to a conical percolator, and gradually pour upon it the remainder of the Diluted Alcohol. When the tincture has ceased to pass, evaporate it, by means of a water-bath, at a temperature not exceeding 160°, to half a pint; then filter, and, having added the Sugar, dissolve it with the aid of a gentle heat, and strain the solution while hot." *U. S.*

This is essentially the second of the two formulas given in the Pharmacopœia of 1850; the first having been omitted in the present edition, as quite superannuated. There is no doubt that, if the existing formula be carried duly into

* Great difficulty has been experienced in making this preparation so as to keep well. Various improvements upon the former officinal formula have been suggested. Dr. Cummings, of Portland, Maine, proposed to use diluted acetic acid as the menstruum for squill, and diluted alcohol for seneka; and thought that a syrup might thus be made which would not ferment. (*Am. Journ. of Pharm.*, xxviii. 397.) Mr. A. P. Sharp, of Baltimore, has found great satisfaction from the following method of proceeding. As soon as one portion of the syrup has been made for use, he begins to prepare another in the following manner. Coarsely powdered seneka and squill, of each ℥viij, are macerated with a gallon of a mixture of one part of alcohol and two of water, and allowed to stand till the first portion is nearly consumed, sometimes for two or three months, when the mixture is expressed or submitted to percolation. The tincture is then evaporated, till the alcohol has been driven off, the residue is filtered cold, lbvij of sugar are added, the liquid is evaporated without boiling to Ovj, is strained if necessary, and a grain of tartar emetic added for each f℥j. (*Ibid.*, xxvii. 220.) But the improvement in the officinal formula, it is hoped, will obviate all necessity for substituted formulas in future. — *Note to the eleventh and twelfth editions.*

execution, it will yield an excellent preparation. But, in consequence of the abundance of a pectin-like matter in seneka, it is difficult to get the syrup quite clear without clarification with albumen. The syrup affords a very convenient mode of exhibiting seneka in pectoral complaints. It may be given as a stimulant expectorant in the dose of one or two fluidrachms. W.

SYRUPUS SENNÆ. *Br. Syrup of Senna.*

"Take of Senna, broken small, *sixteen ounces* [avoirdupois]; Oil of Coriander *three minims;* Refined Sugar *twenty-four ounces* [avoird.]; Distilled Water *five pints* [Imperial measure], or *a sufficiency;* Rectified Spirit *two fluidounces.* Digest the Senna in seventy [fluid]ounces of the Water for twenty-four hours; press and strain. Digest the mark in thirty [fluid]ounces of the Water for six hours; press and strain. Evaporate the mixed liquors to ten fluidounces, and, when cold, add the Rectified Spirit, previously mixed with the Oil of Coriander. Clarify by filtration, and wash what remains on the filter with Distilled Water, until the washings make up the filtrate to sixteen fluidounces. Then add the Sugar, and dissolve by means of a gentle heat. The product should weigh two pounds ten ounces [avoird.], and should have the sp. gr. 1·310." *Br.*

The present British syrup, which has superseded the former syrups of the London and Edinburgh Colleges, differs from them, as well as from that of the U. S. Pharmacopœia of 1850, very greatly in strength; so that, in prescribing it, physicians accustomed to the doses of the former syrups must be on their guard not very seriously to overdose their patients. The syrup, as made by the above formula, contains the strength of about thirty grains of senna in each fluidrachm, and should rank with the Fluid Extracts rather than the Syrups. The dose for an adult would be one or two fluidrachms; but for children, for whom it was originally intended, not more than from one-eighth to one-quarter of that quantity, according to the age. It has been omitted in the present edition of the U. S. Pharmacopœia, under the impression, we presume, that its place might be supplied by the fluid extract. W.

SYRUPUS TOLUTANUS. *U. S., Br. Syrup of Tolu.*

"Take of Tincture of Tolu *two fluidounces;* Carbonate of Magnesia *one hundred and twenty grains;* Sugar [refined], in coarse powder, *twenty-six troyounces;* Water *a pint.* Rub the Tincture of Tolu first with the Carbonate of Magnesia and two troyounces of the Sugar, then with the Water gradually added, and filter. To the filtered liquid add the remainder of the Sugar, and, having dissolved it with the aid of a gentle heat, strain the solution while hot." *U. S.*

"Take of Balsam of Tolu *one ounce and a quarter* [avoirdupois]; Refined Sugar *two pounds* [avoird.]; Distilled Water *one pint* [Imperial measure], or *a sufficiency.* Boil the Balsam in the Water for half an hour in a lightly covered vessel, stirring occasionally. Then remove from the fire, and add Distilled Water, if necessary, so that the liquid shall measure sixteen [fluid]ounces. Filter the solution when cold, add the Sugar, and dissolve with the aid of a steam or water-bath. The product should weigh *three pounds* [avoird.], and should have the sp. gr. 1·330." *Br.*

In the U. S. process, the tincture of tolu is rubbed with the carbonate of magnesia and a little sugar, and afterwards with the water, in order to enable this fluid to take from the tincture all that it is capable of dissolving; the carbonate of magnesia and the precipitated resin of the tincture being separated by filtration. The process is then completed by forming a syrup with the filtered liquid. It is in accordance with a formula proposed by Mr. J. D. Finley, and published in a note in the eleventh edition of the U. S. Dispensatory. The resulting syrup is beautifully and permanently clear, and has very decidedly the flavour of the balsam. In the British process the soluble principles of the balsam are extracted by

boiling it with water, but with great waste of the material, as the water dissolves but a small portion of the active matter of the balsam. To obviate this waste, the same portion of balsam is, according to Mr. Brande, usually employed in successive operations; and it long continues to impart odour and taste to boiling water. The British syrup may have an equal and possibly a finer flavour, but is less efficient medicinally than that of the U. S. Pharmacopœia. At best, however, the syrup of tolu is a feeble preparation, and is used chiefly to impart its agreeable flavour to mixtures.

Off. Prep. Trochisci Cubebæ, *U. S.* W.

SYRUPUS ZINGIBERIS. *U. S., Br. Syrup of Ginger.*

"Take of Tincture of Ginger *six fluidounces;* Carbonate of Magnesia *half a troyounce;* Sugar [refined], in coarse powder, *one hundred and eight troyounces;* Water *four pints.* Evaporate the Tincture to three fluidounces with a gentle heat; then rub it first with the Carbonate of Magnesia and two troyounces of the Sugar, and afterwards with the Water gradually added, and filter. To the filtered liquid add the remainder of the Sugar, and, having dissolved it with the aid of a gentle heat, strain the solution while hot." *U. S.*

"Take of Tincture of Ginger *one fluidounce;* Syrup *seven fluidounces.* Mix with agitation." *Br.*

The U. S. process for syrup of ginger is upon the same amended plan as that adopted for Syrup of Tolu, and yields a fine preparation entirely free from turbidness. As the active principles of ginger are soluble in water, nothing is lost by the precipitation of the concentrated tincture by means of water, and the separation of the resinous matter by filtration. The British syrup being made by the simple incorporation of the tincture with syrup, has of course all the strength of the ginger, but is inferior to the U. S. preparation in appearance and flavour. The old plan of using water as the menstruum has been entirely abandoned, as the syrup thus made is encumbered with mucilage and starch, and consequently rendered more liable to decomposition.

In order that the preparation may be of the proper strength, it is necessary that the tincture should have been made with the best Jamaica ginger. The syrup of ginger is much used as a warm stomachic addition to tonic and purgative infusions or mixtures, and to impart flavour to drinks, particularly to carbonic acid water.

Off. Prep. Trochisci Zingiberis, *U. S.* W.

TINCTURÆ.

Tinctures.

Tinctures, in the pharmaceutical sense of the term, are solutions of medicinal substances in alcohol or diluted alcohol, prepared by maceration, digestion, or percolation. Solutions in spirit of ammonia and ethereal spirit are embraced under the same denomination, but are severally distinguished by the titles of *ammoniated tinctures* and *ethereal tinctures.* The advantages of alcohol as a menstruum are, that it dissolves principles which are sparingly or not at all soluble in water, and contributes to their preservation when dissolved; while it leaves behind some inert substances which are dissolved by water. In no instance, however, is absolute alcohol employed. The U. S. Pharmacopœia directs it of the sp. gr. 0·835; the British, 0·838. When of these densities it contains water, and is capable of dissolving more or less of substances which are insoluble in anhydrous alcohol; while its solvent power, in relation to bodies soluble in that fluid, is sufficient for all practical purposes. Diluted alcohol or proof spirit is often preferable to officinal alcohol; as it is capable of extracting a larger proportion of those active principles of plants which require an aqueous menstruum, at the

same time that it is strong enough, in most instances, to prevent spontaneous decomposition, and has the advantages of being cheaper and less stimulating.* The diluted alcohol of the different Pharmacopœias is not of the same strength, that of the United States consisting of equal measures of officinal alcohol and water, and having the sp. gr. 0·941; while that of the British, called *Spiritus Tenuior* or Proof Spirit, has the sp. gr. 0·920. The difference, however, is not very material. Alcohol or rectified spirit is preferred as the solvent, when the substance to be extracted or dissolved is nearly or quite insoluble in water, as in the instances of the resins, guaiac, camphor, and the essential oils. The presence of water is here injurious, not only by diluting the menstruum, but by exercising an affinity for the alcohol which interferes with its solvent power. Thus, water, added to an alcoholic solution of one of these bodies, produces a precipitate by abstracting the alcohol from it. Diluted alcohol or proof spirit is employed, when the substance is soluble both in alcohol and water; or when one or more of the ingredients are soluble in the one fluid, and one or more in the other, as in the case of those vegetables which contain extractive or tannin, or the native salts of the organic alkalies, or gum united with resin or essential oil. As these include the greater number of medicines from which tinctures are prepared, diluted alcohol is most frequently used.

In the preparation of the tinctures, the medicine should be in the dry state, and properly comminuted by being bruised, sliced, or pulverized. It is usually better in the condition of a coarse than of a very fine powder; as in the latter it is apt to agglutinate, and thus present an impediment to the penetration of the menstruum. When several substances differing in solubility are employed, they should be added successively to the spirit, those least soluble first, those most so last; as otherwise the menstruum might become saturated with the ingredient for which it has the strongest affinity, and thus be rendered incapable of dissolving a due proportion of the others.

Until recently, tinctures have been universally prepared by maceration or digestion. The Edinburgh College directed digestion to be continued usually for seven days. Our own Pharmacopœia formerly directed maceration at ordinary temperatures, and extended the period to two weeks. The latter plan was preferable, as it was more convenient and equally effectual, the lower temperature being compensated by the longer maceration. In several instances in which maceration is ordered in our Pharmacopœia, it is still continued for two weeks; but the period is very properly altered to suit the character of the substance acted on, being sometimes shortened to a week when the medicine readily yields its virtues to the menstruum, and sometimes continued no longer than is necessary for its solution, when it is wholly soluble, as in the tinctures of iodine and tolu. When circumstances require that the tincture should be speedily prepared, digestion may be resorted to. Care should always be taken to keep the vessels well stopped, in order to prevent the evaporation of the alcohol. The materials should be frequently shaken during the digestion or maceration; and this caution is especially necessary when the substance acted on is in the state of powder. The tincture should not be used till the maceration is completed; when it should be separated from the dregs either by simply filtering it through paper, or, when force is requisite, by first expressing it through linen, and subsequently filtering.

The plan of preparing tinctures by percolation has recently been extensively

* Mr. Wm. Bastick, in a communication to the Pharmaceutical Journal and Transactions, states, as the result of his experience, that most of the tinctures prepared with proof spirit or diluted alcohol undergo deterioration by time, in consequence of acetous fermentation taking place in the alcoholic fluid. The tinctures most prone to this change are those of senna, rhubarb, columbo, henbane, digitalis, bark, hops, aloes, and the compound tincture of cinnamon. The best preventive is to keep them in full and well-closed bottles, at a low temperature. (*Am. Journ. of Pharm.*, xx. 47.)

adopted; and has been found to answer well when skilfully executed. In the U. S. Pharmacopœia of 1850, and in the late Ed. Pharmacopœia, this mode of preparation was given as an alternative in numerous instances; and would probably have been exclusively recommended in some, except for its liability to fail in inexperienced hands. In the present edition of our national standard, percolation has been adopted as the rule; maceration being directed in a few instances in which it was deemed preferable, and the alternative expressly allowed only in a single tincture, that, namely, of aloes and myrrh. The British Pharmacopœia, preferring maceration or digestion in several instances, has adopted percolation as a general rule; but, as if unprepared to trust this process alone, has combined with it a preliminary maceration of forty-eight hours, and a final expression, so as to separate the last remains of the tincture from the dregs. Perhaps these modifications may be desirable in instances where the operator is insufficiently skilful; but percolation, properly managed, is of itself adequate to all the desired purposes, even to the removal of almost the last drop of impregnated menstruum from the dregs; and, in our Pharmacopœia, it is taken for granted that the apothecary has acquired the requisite skill. Where the operator cannot trust himself in this respect, it would be better to recur to the old method of maceration for two weeks. The reader will find rules for the proper management of the process of percolation at *pages* 894 and 905. It has been objected to this process that it yields tinctures of variable strength, according to the skill with which it is conducted; but, from numerous experiments performed, in reference to this point, by M. H. Buignet, of Paris, it appears that the tinctures made by percolation are quite as equable in strength as those prepared by maceration, while they uniformly contain more of the soluble matter of the drug in proportion to the quantity of menstruum. The same writer states that he has constantly found three parts of alcohol, used in this method, to one of the material acted on, sufficient almost wholly to exhaust drugs of their soluble matter. He has derived no advantage from the preliminary maceration usually practised. (*Journ. de Pharm.*, Sept. 1857, p. 172.) M. Personne, however, has inferred, from his own observation, that five parts of alcohol are required by most substances. (*Ibid.*, Avril, 1860, p. 274.) Our own Pharmacopœia generally exceeds this. It has been contended in opposition to percolation, applied to the preparation of tinctures, that the menstruum in this process is apt to load itself with substances, which, after the preparation of the tincture, are deposited, carrying down with them more or less of the active matter; but M. Vauflart asserts that more than twenty years of observation has demonstrated to him, that tinctures by displacement, properly filtered, deposit no more than, at the end of a certain period, those deposit prepared by maceration. (*Ibid.*, Avril, 1862, p. 262.) Finally, all agree that the percolated tinctures are apt to contain more of the soluble matter of the drug; and the objections all resolve themselves into a question of skill on the part of the operator.

Another mode of exhausting medicines by spirit has been proposed by Dr. H. Burton. It consists in suspending in the solvent, immediately under its surface, the solid matter contained loosely in a bag. The liquid in contact with the bag, becoming heavier by impregnation with the matters dissolved, sinks to the bottom; its place is supplied with a fresh portion, which in its turn sinks; and thus a current is established, which continues until the solid substance is exhausted, or the liquid saturated. During the maceration, the bag should be occasionally raised above the surface of the liquor in the bottle, allowed to drain, and then again immersed. It is asserted that the period of maceration is much shortened in this way. (*Lond. Med. Gaz.*, Aug. 30, 1844.)*

* For this mode of preparing tinctures, Mr. Samuel Gale has proposed the use of a cylindrical stoneware vessel, with a diaphragm capable of being supported at different heights by projections from the inner surface of the jar, with corresponding notches in the dia-

Tinctures, prepared by adding alcohol to the expressed juice of plants, have been long in use on the Continent of Europe, and have been brought into notice in Great Britain. They are sometimes called in England *preserved vegetable juices*. The tinctures of some of the narcotic plants might no doubt be advantageously prepared in this way, as those of conium, hyoscyamus, and belladonna. Mr. Squire and Mr. Bentley have paid particular attention to these preparations. According to Mr. Squire, the leaves only of the plants should be used, and, in the case of biennial plants, those exclusively of the second year; and they should be preferably collected when the plant is in full flower. Mr. Bentley recommends the following mode of preparation. To the expressed juice, after it has stood for 24 hours, and deposited its feculent matter, alcohol of 0·838 is to be added in the proportion of one part by measure to four of the juice; and, after another period of 24 hours, the liquor is to be filtered. This proportion of alcohol has been found sufficient for the preservation of the juice, while it causes the precipitation of the suspended mucilaginous matter. But, though these preserved juices are often energetic, yet it is obvious that tinctures prepared from the fresh plant must be still more so; as they contain necessarily not only the soluble active matter of the juice, but that also which, when the juice is expressed, is left in the solid residue of the plant. Three of them have been introduced into the British Pharmacopœia, under the name simply of *Succi* or *Juices*.

Tinctures should be kept in bottles accurately stopped, in order to prevent evaporation, which might, in some instances, be attended with serious inconvenience, by increasing their strength beyond the officinal standard.

Medicines are most conveniently administered in tincture, which act in small doses; as the proportion of alcohol in which they are dissolved is insufficient to produce an appreciable effect. Those which must be given in large doses should be cautiously employed in this form, lest the injury done by the menstruum should more than counterbalance their beneficial operation. This remark is particularly applicable to chronic cases, in which the use of tinctures is apt to lead to the formation of habits of intemperance. The tinctures of the weaker medicines are more frequently given as adjuvants of other remedies than with the view of obtaining their own full effects upon the system.

The following general directions are given in the *U. S. Pharmacopœia*.

"When tinctures are prepared by percolation, great care should be taken to observe the directions given at page 3 [*page* 905 of this Dispensatory], so that the substances treated may be, as far as possible, exhausted of their soluble principles, and a perfectly clear tincture obtained. When prepared by maceration, they require to be frequently shaken during the process, which should be conducted in glass bottles well stopped."

phragm, to permit its easy passage to the lower ledges. The material is to be placed upon the diaphragm, and kept covered with the menstruum. (See *Am. Journ. of Pharm.*, xxii. 381, from *Pharm. Journ.*) The infusion jars described and figured in a note in *page* 1176 may be used also for preparing tinctures by maceration.

The following is a table, showing the mode in which the tinctures of the medicines enumerated should be prepared, in the opinion of the Society of Pharmacy at Paris, as given at their session on June 25, 1862.

By Percolation with alcohol of 60°.	*By Percolation with alcohol of* 80°.	*By Maceration with alcohol of* 60°.	*By Maceration with alcohol of* 80°.	*By Maceration with alcohol of* 90°.
Belladonna.	Valerian.	Aloes.	Castor.	Assafetida.
Conium.	Cinnamon.	Arnica flowers.	Columbo.	Balsam of Peru.
Hyoscyamus.	Red Cinchona.	Catechu.	Colchicum Seed.	Balsam of Tolu.
Stramonium.	Yellow Cinchona.	Colchicum bulbs.	Cloves.	Benzoin.
Digitalis.		Gentian.	Ginger.	Ammoniac.
Quassia.		Ipecacuanha.	Jalap.	Myrrh.
Pale Cinchona.		Musk.	Nux Vomica.	Scammony.
Rhatany		Rhubarb.	Saffron.	
Senna.		Squill.	Vanilla.	

The officinal Preparations formerly belonging to this class, which have been omitted in the present U. S. and Br. Pharmacopœias, are *Tinctura Ammoniæ Composita*, Lond., *Essentia Carui*, Dub., *Tinct. Cassiæ*, Ed., *Tinct. Castorei Ammoniata*, Ed., *Tinct. Cinchonæ Pallidæ*, Lond., *Tinct. Cinnamomi Comp.*, U. S., Lond., Ed., Dub., *Tinct. Colchici Comp.*, Lond., *Tinct. Cuspariæ*, Ed., *Essentia Fœniculi*, Dub., *Tinct. Lactucarii*, Ed., *Tinct. Matico*, Dub., *Essentia Myristicæ Moschatæ*, Dub., *Essentia Pulegii*, Dub., *Tinct. Opii Ammoniata*, Ed., *Essentia Pimentæ*, Dub., *Tinct. Quassiæ Comp.*, Ed., *Tinct. Rhei Comp.*, Lond., Dub., *Tinct. Rhei et Gentianæ*, U. S., Ed., *Essentia Rosmarini*, Dub., *Tinct. Sennæ Comp.*, Ed., and *Tinct. Sennæ et Jalapæ*, U. S. *Essentia Anisi*, Dub., and *Essentia Cinnamomi*, Dub., have been transferred to the *Spirits* with changed names, and some change of strength; as also have the *Tinct. Camphoræ*, U. S., Ed., Dub., the *Tinct. Olei Menthæ Piperitæ*, U. S., and the *Tinct. Olei Menthæ Viridis*, U. S.; while the *Tinct. Saponis Camphorata*, U. S., has been placed among the *Liniments* with the altered name of *Linimentum Saponis*.

TINCTURA ACONITI FOLII. *U. S. Tincture of Aconite Leaf.*

"Take of Aconite Leaf, recently dried and in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of Tincture are obtained." *U. S.*

This is a good preparation of aconite when made from the recently dried leaves, and may be given in the dose of twenty or thirty drops. A saturated tincture prepared from the root is now more used. It is much stronger than the tincture of the leaves, and great care should be taken not to confound them in prescription. (See *Tinctura Aconiti Radicis.*) W.

TINCTURA ACONITI RADICIS. *U. S.* TINCTURA ACONITI. *Br. Tincture of Aconite Root.*

"Take of Aconite Root, in fine powder, *twelve troyounces;* Alcohol *a sufficient quantity.* Moisten the powder with six fluidounces of Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

"Take of Aconite Root, in fine powder, *two ounces and a half* [avoirdupois]; Rectified Spirit *one pint* [Imperial measure]. Macerate the Aconite Root for forty-eight hours, with *fifteen* [fluid]*ounces* of the Spirit, in a close vessel, agitating occasionally; then transfer to a percolator, and, when the fluid ceases to pass, pour into the percolator the remaining five [fluid]ounces of the Spirit. As soon as the percolation is completed, subject the contents of the percolator to pressure, filter the product, mix the liquids, and add sufficient Rectified Spirit to make one pint [Imp. meas.]. This tincture has half the strength of Tinctura Aconiti, *Dub.*, and one-third of the strength of Tinctura Aconiti, *Lond.*" *Br.*

The tincture of the U. S. Pharmacopœia has three times the strength of the British. It is much stronger than that of the leaves, and too much caution cannot be observed to avoid mistaking one for the other. In preparing it, each step of the process must be carefully attended to. The root should be thoroughly comminuted, and very carefully packed in the percolator, and the displacing menstruum very gradually added. As annoyance is often occasioned in powdering aconite by the irritating dust which is apt to rise, it is best prepared by grinding in a mill; and, if the operator does not happen to have such an instrument at his command, Prof. Procter suggests that sufficient alcohol should be added to the root in a mortar, to prevent the rising of the dust. (*Am. Journ. of Pharm.*, March, 1861, p. 103.) The dose to begin with is from five to ten drops, which may be repeated three times a day, and gradually increased, if necessary, until its

peculiar effects are experienced. That of the British tincture is three times as much We would here repeat the caution, already given when treating of Aconite in the first part of this work, that physicians should be careful, in prescribing either of the tinctures of aconite, to give the whole name of the one they intend, as other wise serious consequences may ensue.* W.

TINCTURA ALOËS. *U. S., Br. Tincture of Aloes.*

"Take of Socotrine Aloes, in fine powder, *a troyounce;* Liquorice [extract] *three troyounces;* Alcohol *half a pint;* Distilled Water *a pint and a half.* Macerate for fourteen days, and filter through paper." *U. S.*

"Take of Socotrine Aloes, in coarse powder, *half an ounce* [avoirdupois]; Extract of Liquorice *one ounce and a half* [avoird.]; Proof Spirit *one pint* [Imperial measure]. Macerate for seven days, filter the liquor, and add sufficient Proof Spirit to make one pint [Imp. meas.]." *Br.*

The original tincture of aloes of the U. S. Pharmacopœia was prepared with the officinal diluted alcohol, without the addition of water. At present it is little more than an infusion, with the addition of sufficient alcohol to prevent spontaneous decomposition. But, while this change has been made in the U. S. formula, so as to produce conformity with the British Colleges, in the late construction of the British Pharmacopœia, their old formula has been abandoned, and the one forsaken by us adopted. The liquorice is in both formulas added to cover the taste of the aloes; but it answers the end imperfectly, and the preparation, on account of its unpleasant bitterness, is little used, aloes being generally administered in the form of pill. M. Menière says of the tincture of aloes that it deposits crystals of aloïn, which adhere to the sides of the bottle, and in the upper part of it a yellow resinous matter. (*Journ. de Pharm.*, Avril, 1861, p. 289.) The dose is from half a fluidounce to a fluidounce and a half. Tincture of aloes is highly recommended by M. Delioux as a local remedy in old atonic ulcers, bed-sores, and suppurating wounds, to which it may be applied on lint. (*Pharm. Journ.*, July, 1864, p. 38.) W.

TINCTURA ALOËS ET MYRRHÆ. *U. S.* TINCTURA ALOES COMPOSITA. *Lond. Tincture of Aloes and Myrrh.*

"Take of Socotrine Aloes, in moderately fine powder, Myrrh, in moderately fine powder, each, *three troyounces;* Saffron, in moderately coarse powder, *a troyounce;* Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with two fluidounces of Alcohol, pack it moderately in a conical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained. This Tincture may also be prepared by macerating the powders with two pints of Alcohol for fourteen days, and filtering through paper." *U. S.*

This tincture is a modification of the *elixir proprietatis* of Paracelsus. The saffron, which has been retained in compliance with former prejudices, can add little to the efficacy of the preparation; and, being very expensive, has with great propriety been much reduced in the U. S. formula. It serves, however, to impart a richness to the tincture, the want of which might be considered a defect by those accustomed to its use.

* The tincture proposed by Dr. Fleming should always be expressly designated when prescribed. It is considerably stronger than the officinal; and several deaths have occurred from the use of it. The following is his formula. Take of the root, carefully dried and finely powdered, *sixteen* (troy) *ounces;* Alcohol *sixteen fluidounces.* Macerate for four days, put into a percolator, and add alcohol until twenty-four fluidounces are obtained. Not more than five drops of this should be given as a commencing dose, to be increased till its peculiar effects are experienced.

Prof. Procter proposes, in order to obtain a strong tincture, and at the same time completely to exhaust the root, to continue the percolation until 50 or 100 per cent. more of the filtered liquor is obtained than is wanted, and then to reduce this to the proper measure by means of a water-bath.—*Note to the eleventh edition.*

The tincture is purgative, tonic, and emmenagogue, and is considerably employed in chlorosis, and other disordered states of health in females, connected with suppressed, retained, or deficient menstruation, and with a constipated state of bowels. It may also be used as a stomachic laxative in cold, languid habits, independently of menstrual disorder. The dose is from one to two fluidrachms. W.

TINCTURA ARNICÆ. *U. S., Br. Tincture of Arnica.*

"Take of Arnica [flowers] *six troyounces;* Alcohol *a pint and a half;* Water *half a pint;* Diluted Alcohol *a sufficient quantity.* Mix the Alcohol and Water, and, having moistened the Arnica slightly with the mixture, bruise it thoroughly in a mortar. Then pack it firmly in a cylindrical percolator, and pour upon it, first the remainder of the mixture, and afterwards sufficient Diluted Alcohol to make the tincture measure two pints." *U. S.*

The *British Pharmacopœia* gives directions for preparing this Tincture from *an avoirdupois ounce* of Arnica Root, in fine powder, and *an Imperial pint* of Rectified Spirit, precisely the same as those for preparing Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

Either alone, or diluted with water, soap liniment, &c., tincture of arnica is often applied popularly to bruises, sprains, tumours, and local rheumatic pains, under the impression that it has extraordinary healing powers. It probably acts favourably in some instances as a gentle irritant. If given internally, the dose would be from thirty minims to two fluidrachms. W.

TINCTURA ASSAFŒTIDÆ *U. S., Br. Tincture of Assafetida.*

"Take of Assafetida, bruised, *four troyounces;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U. S.*

"Take of Assafetida, in small fragments, *two ounces and a half* [avoirdupois]; Rectified Spirit *one pint* [Imperial measure]. Macerate for seven days, strain, filter, and add sufficient Rectified Spirit to make one pint [Imp. meas.]." *Br.*

This tincture becomes milky on the addition of water, in consequence of the separation of the resin. It possesses all the virtues of assafetida. The medium dose is a fluidrachm.

Off. Prep. Enema Assafœtidæ, *Br.* W.

TINCTURA AURANTII. *Br. Tincture of Orange Peel.*

The *British Pharmacopœia* directs this Tincture to be prepared from *two avoirdupois ounces* of Bitter Orange Peel, "cut small and bruised," and *one Imperial pint* of Proof Spirit, in the same manner precisely as the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

It is the peel of the Seville orange which is directed in this process; and the outer part only should be used, the inner whitish portion being inert. The tincture of orange peel is employed as a grateful addition to infusions, decoctions, and mixtures.

Off. Prep. Syrupus Aurantii, *Br.;* Tinctura Quinæ Composita, *Br.* W.

TINCTURA BELLADONNÆ. *U. S., Br. Tincture of Belladonna.*

"Take of Belladonna Leaf, recently dried and in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* directs this Tincture to be prepared from *one avoirdupois ounce* of Belladonna Leaves, in coarse powder, and *one Imperial pint* of Proof Spirit, in the same manner precisely as the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.) "This Tincture has about half the strength of Tinctura Belladonnæ, *Lond., Dub.*" *Br.*

According to Menière, this tincture deposits on standing a gray pulverulent substance, starch and gum, and cubical crystals of an undetermined character

(*Journ. de Pharm.*, Avril, 1861, p. 289.) The U. S. tincture is an efficient preparation when made from the recently dried leaves; but the imported leaves are of very uncertain strength, and a tincture prepared from them is to be less relied upon than the extract. The dose is from fifteen to thirty drops. That of the British tincture is at least twice as much. W.

TINCTURA BENZOINI COMPOSITA. *U. S.*, *Br. Compound Tincture of Benzoin.*

"Take of Benzoin, in coarse powder, *three troyounces;* Socotrine Aloes, in coarse powder, *half a troyounce;* Storax *two troyounces;* Balsam of Tolu *a troyounce;* Alcohol *two pints.* Macerate for fourteen days, and filter through paper." *U. S.*

"Take of Benzoin, in coarse powder, *two ounces* [avoirdupois]; Prepared Storax *one ounce and a half* [avoird.]; Balsam of Tolu *half an ounce* [avoird.]; Socotrine Aloes *one hundred and sixty grains;* Rectified Spirit *one pint* [Imperial measure]. Macerate for seven days, filter, and add sufficient Rectified Spirit to make one pint [Imp. meas.]." *Br.*

This tincture is a stimulating expectorant, occasionally used in chronic catarrhal affections. It has been recommended also in chronic dysentery, with a view to its alterative action on the ulcerated surface of the colon; but it is most employed as a local application to indolent ulcers, chapped nipples, &c. It has been found useful injected into the nostrils in obstinate epistaxis. (*Braithwaite*, No. 37, p. 58.) It is the *balsamum traumaticum* of the older Pharmacopœias, and may be considered as a simplified form of certain complex compositions, such as *baume de commandeur*, *Wade's balsam*, *Friar's balsam*, *Jesuits' drops*, *&c.*, which were formerly in repute, and are still esteemed among the vulgar as pectorals and vulneraries. It is also an ingredient in *Turlington's balsam*, which is a popular remedy in this country for the same purposes.* It is scarcely necessary to state that the application of these preparations to fresh wounds must frequently prove injurious, by inducing too much inflammation, and thus preventing union by the first intention. The compound tincture of benzoin is decomposed by water. The dose is from thirty minims to two fluidrachms. A variety of *court plaster* is made by applying to black silk, by means of a brush, first a solution of isinglass, and afterwards an alcoholic solution of benzoin. W.

TINCTURA BUCCO. *Br. Tincture of Buchu.*

This Tincture is directed, in the *British Pharmacopœia*, to be prepared from *two and a half avoirdupois ounces* of Buchu, bruised, and *one Imperial pint* of Proof Spirit, in the same manner precisely as Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384).

This tincture has the virtues of buchu leaves, and may be given in the dose of from one to four fluidrachms, either simply diluted with water, or as an addition to the infusion of the leaves. W.

TINCTURA CALUMBÆ. *U. S.*, *Br. Tincture of Columbo. Tincture of Calumbo. Br.*

"Take of Columbo, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, transfer it to a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* directs this Tincture to be prepared from *two and a half avoirdupois ounces* of bruised Columbo, and *one Imperial pint* of

* The following is the formula for *Turlington's balsam* adopted by the Philadelphia College of Pharmacy. "Take of Alcohol Oviij, Benzoin ℥xij, Liquid Storax ℥iv, Socotrine Aloes ℥j, Peruvian Balsam ℥ij, Myrrh ℥j, Angelica Root ℥ss, Balsam of Tolu ℥iv, Extract of Liquorice Root ℥iv. Digest for ten days, and strain." (*Journ. of the Phil. Col. of Pharm.*, v. 28.)

Proof Spirit, in the same manner precisely as directed for the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

The tincture of columbo of the U. S. Pharmacopœia was, with great propriety, considerably increased in strength at the revision of 1840. The larger the proportion of the tonic is to the alcohol in these bitter tinctures, the better are they calculated to meet the indications for which they are usually prescribed. When the proportion is very small, the tonic power of the bitter is lost in the stimulant influence of the alcohol. Mr. Jos. Ince recommends that the tincture should be prepared from the root as found in the shops, without further slicing or powdering it. Made as he proposes, the tincture is clear and bright; while if the powdered root is used it will be very turbid, even after filtration. (*Pharm. Journ.*, xiv. 491.) The tincture of columbo may be added to tonic infusions or decoctions, to increase their stimulant power; but, like all the other bitter tinctures, should be used with caution. The dose is from one to four fluidrachms. W.

TINCTURA CANNABIS. *U. S.* Tinctura Cannabis Indicæ. *Br. Tincture of Hemp. Tincture of Indian Hemp.*

"Take of Purified Extract of Hemp *three hundred and sixty grains;* Alcohol *a pint.* Dissolve the Extract in the Alcohol, and filter through paper." *U. S.*

"Take of Extract of Indian Hemp *one ounce* [avoirdupois]; Rectified Spirit *one pint* [Imperial measure]. Dissolve the Extract of Hemp in the Spirit." *Br.*

The American reader must take care not to confound the Indian Hemp, here alluded to, with Apocynum Cannabinum, known by the same name in this country. The dose, equivalent to a grain of the extract, is twenty-two minims or about forty drops, to be gradually increased till its effects are experienced. W.

TINCTURA CANTHARIDIS. *U. S., Br. Tincture of Cantharides. Tincture of Spanish Flies.*

"Take of Cantharides, in fine powder, *a troyounce;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with half a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* directs this Tincture to be prepared from *a quarter of an avoirdupois ounce* of Cantharides, in coarse powder, and *one Imperial pint* of Proof Spirit, in the same manner precisely as directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This tincture is one of the most convenient forms for the internal use of Spanish flies, the virtues of which it possesses to their full extent. (See *Cantharis.*) When long kept it deposits fatty matter, cantharidin in rhomboidal tables, and other crystals of a quite different form. (Menière, *Journ. de Pharm.*, Avril, 1861, p. 289.) It is occasionally employed externally as a rubefacient; but its liability to vesicate should be taken into consideration. The British tincture is too feeble; containing the virtues of only 0·68 of a grain of cantharides in a fluidrachm. The dose of the U. S. tincture is from twenty drops to a fluidrachm, repeated three or four times a day. W.

TINCTURA CAPSICI. *U. S., Br. Tincture of Capsicum. Tincture of Cayenne Pepper.*

"Take of Capsicum, in fine powder, *a troyounce;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with half a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* directs this Tincture to be prepared from *three-quarters of an avoirdupois ounce* of bruised Capsicum, and *one Imperial pint* of Rectified Spirit, in the same manner precisely as directed for the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This preparation of capsicum is a useful stimulant in very low states of the system with great gastric insensibility, as in malignant scarlet and typhus fevers, and in the cases of drunkards. It may also be used as a gargle, diluted with rose-water or some mucilaginous fluid. (See *Capsicum.*) Applied by means of a camel's hair pencil to the relaxed uvula, it sometimes produces contraction, and relieves prolapsus of that part. The dose is one or two fluidrachms.

Off. Prep. Trochisci Catechu, *Br.* W.

TINCTURA CARDAMOMI. *U. S. Tincture of Cardamom.*

"Take of Cardamom, in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

This tincture is an agreeable aromatic, and may be advantageously added to tonic and purgative infusions. The dose is one or two fluidrachms. W.

TINCTURA CARDAMOMI COMPOSITA. *U. S., Br. Compound Tincture of Cardamom.*

"Take of Cardamom, in moderately fine powder, *three hundred and sixty grains;* Caraway, in moderately fine powder, *one hundred and twenty grains;* Cinnamon, in moderately fine powder, *three hundred grains;* Cochineal, in moderately fine powder, *sixty grains;* Clarified Honey *two troyounces;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with half a fluidounce of Diluted Alcohol, pack it in a cylindrical percolator, and gradually pour Diluted Alcohol upon it until two pints and six fluidounces of tincture are obtained. Lastly, mix this with the Clarified Honey, and filter through paper." *U. S.*

The *British Pharmacopœia* takes of Cardamom, bruised, and Caraway, bruised, each, *a quarter of an avoirdupois ounce;* Raisins, freed from their seeds, *two avoirdupois ounces;* Cinnamon, bruised, *half an avoirdupois ounce;* Cochineal, in powder, *sixty grains;* and Proof Spirit *one Imperial pint;* and directs that the tincture should be prepared in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This is a very agreeable aromatic tincture, occasionally used as a carminative in the dose of one or two fluidrachms, but more frequently as an addition to mixtures, infusions, &c., which it renders pleasant to the taste, and acceptable to the stomach. The substitution of honey in the present U. S. formula for the raisins in that of 1850, may be regarded as an improvement, at least in a pharmaceutical point of view, as it facilitates the process, and, considering the unequal quality of raisins, gives more precision to the result.

Off. Prep. Decoctum Aloes Compositum, *Br.* W.

TINCTURA CASCARILLÆ. *Br. Tincture of Cascarilla.*

The *British Pharmacopœia* directs this Tincture to be prepared from *two and a half avoirdupois ounces* of bruised Cascarilla, and *one Imperial pint* of Proof Spirit, in the same manner precisely as directed for the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This tincture has the properties of cascarilla, but is seldom if ever used in this country. W.

TINCTURA CASTOREI. *U. S., Br. Tincture of Castor.*

"Take of Castor, bruised, *two troyounces;* Alcohol *two pints.* Macerate for seven days, express, and filter through paper." *U. S.*

"Take of Castor *one ounce* [avoirdupois]; Rectified Spirit *one pint* [Imperial measure]. Macerate for seven days, strain, express, filter, and add sufficient Rectified Spirit to make one pint [Imp. meas.]." *Br.*

As castor yields little if any of its virtues to water, alcohol is a better solvent

than proof spirit. It is said also to form a more grateful preparation. The Russian castor should always be preferred when attainable. It deposits on standing a yellow organic substance, which, when moistened with water, exhibits animalcules under the microscope. (*Menière.*) This tincture is used for the same purposes as castor in substance. The dose is from thirty minims to two fluidrachms. W.

TINCTURA CATECHU. *U. S.*, *Br.* *Tincture of Catechu.*

"Take of Catechu, in moderately coarse powder, *three troyounces;* Cinnamon, in moderately coarse powder, *two troyounces;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with a fluidounce of Diluted Alcohol, pack it in a conical glass percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia*, in the process for this Tincture, takes of Catechu, in coarse powder, *two and a half avoirdupois ounces*, of Cinnamon, bruised, *one avoirdupois ounce*, and of Proof Spirit *one Imperial pint*, and proceeds precisely in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This is a grateful astringent tincture, useful in all cases to which catechu is applicable, and in which small quantities of spirit are not objectionable. It may often be advantageously added to cretaceous mixtures in diarrhœa. The dose is from thirty minims to three fluidrachms, which may be given with sweetened water or some mucilaginous liquid, or in port wine when this is not contraindicated. Like the tincture of kino, this is said sometimes to gelatinize when kept. In this state it is unfit for use. W.

TINCTURA CHIRATÆ. *Br.* *Tincture of Chiretta.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Chiretta, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This is a tonic tincture, and may be given in the dose of one or two fluidrachms, three or four times a day. W.

TINCTURA CINCHONÆ. *U. S.* TINCTURA CINCHONÆ FLAVÆ. *Br.* *Tincture of Cinchona. Tincture of Yellow Cinchona. Tincture of Peruvian Bark.*

"Take of Yellow Cinchona, in moderately fine powder, *six troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a glass percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *four avoirdupois ounces* of Yellow Cinchona Bark, in coarse powder, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This tincture is very properly made with a large proportion of bark; as, in the bitter tinctures, it is important that the alcohol should bear as small a proportion to the tonic principle as possible. Even when strongest, however, it cannot, in ordinary cases, be given in doses sufficiently large to obtain the full effect of the bark, without stimulating too highly. Tincture of cinchona is used chiefly as an adjunct to the infusion or decoction of bark, or the solution of sulphate of quinia, to a dose of which it may be added in the quantity of from one to four fluidrachms. W.

TINCTURA CINCHONÆ COMPOSITA. *U. S.*, *Br.* *Compound Tincture of Cinchona. Compound Tincture of Peruvian Bark.*

"Take of Red Cinchona, in moderately fine powder, *four troyounces;* Bitter Orange Peel, in moderately fine powder, *three troyounces;* Serpentaria, in mode-

rately fine powder, *three hundred and sixty grains;* Saffron, in moderately coarse powder, Red Saunders, in moderately fine powder, each, *one hundred and twenty grains;* Diluted Alcohol *a sufficient quantity.* Mix the powders, and, having moistened the mixture with four fluidounces of Diluted Alcohol, pack it firmly in a glass percolator, and gradually pour Diluted Alcohol upon it until two pints and a half of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes of Pale Cinchona Bark, in coarse powder, *two avoirdupois ounces,* Bitter-Orange Peel, cut small and bruised, *one avoird. ounce,* Serpentaria, bruised, *half an avoird. ounce,* Saffron *sixty grains,* Cochineal, in powder, *thirty grains,* and Proof Spirit *one Imperial pint;* and proceeds, with these ingredients, in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti,* page 1384.)

This is the preparation commonly known by the name of *Huxham's tincture of bark.* It is unfortunate that the British Council, following the London and Dublin Colleges, should have selected the feeblest of the officinal varieties of bark for this important tincture. The compound tincture of bark is an excellent stomachic cordial, and, though too feeble in the principles of cinchona to serve as a substitute for that tonic when its full effect is required, may be very usefully employed as an addition to the decoction or infusion, or to the salts of quinia, in low forms of fever, particularly in malignant intermittents and remittents. Huxham was in the habit of uniting with it the *elixir of vitriol,* the aromatic sulphuric acid of the Pharmacopœias. The dose is from one to four fluidrachms.

Under the name of *tinctura cinchonæ ferrata,* a preparation has been considerably employed in Philadelphia, for which the following formula is given by Mr. Samuel Simes, in the *Am. Journ. of Pharm.* (xxv. 402). With *one gallon* of the compound tincture of bark, *one ounce* of hydrated sesquioxide of iron, dried at a temperature not exceeding 130° F., is digested, and the liquor filtered. The tannic acid is removed by the iron forming an insoluble tannate, which with the excess of oxide is separated by the filtration. In order not to lose any portion of the alkaloids which may adhere to the precipitate, this is to be well washed with boiling alcohol, the solution evaporated to dryness, the product dissolved in a little water acidulated with citric acid, and added to the filtered liquor. Lastly, *sixteen grains* of ammonio-citrate of iron are to be added to each fluidounce of the tincture. The dose is a fluidrachm.* W.

TINCTURA CINNAMOMI. *U. S., Br. Tincture of Cinnamon.*

"Take of Cinnamon, in fine powder, *three troyounces;* Alcohol, Water, each, *a sufficient quantity.* Mix Alcohol and Water in the proportion of two measures

* Prof. Procter observes of this preparation that, in consequence of the cincho-tannic acid not being entirely removed by the dry sesquioxide, the preparation blackens upon standing. He proposes to substitute for the sesquioxide in a dried state, the same freshly precipitated, washed, and pressed strongly between folds of bibulous paper.—*Note to the eleventh edition.*

Ferrated Elixir of Cinchona. A formula, by Mr. J. T. Shinn, for a preparation under this name, said to be in considerable use, will be found in the *American Journal of Pharmacy* for May, 1862 (p. 204).

Elixir Cinchonæ Flavæ. The following preparation has been much used in this city, and other parts of the U. States. The formula is that of Mr. A. B. Taylor, and is taken from the *Am. Journ. of Pharm.* (Jan. 1859, p. 18). "Take of Yellow Cinchona 4 *ounces;* Orange peel, recently dried, 2 *ounces;* Ceylon Cinnamon, Coriander seeds, each, *an ounce;* Anise, Caraway, Cardamom, Cochineal, each, 120 *grains;* Brandy *two pints and a half;* Syrup *two pints and a half;* Alcohol and Water, each, *a sufficient quantity.* Reduce the dry substances to moderately fine powder; mix the Brandy with its bulk of water; moisten the powder with four fluidounces of the mixture; and pack it in a conical percolator. Pour on the remainder of the liquid, and continue the percolation with a mixture of one part of alcohol to three parts of water, until six and a half pints of tincture are obtained; then add the syrup and mix them." This is an elegant aromatic tonic, extensively used as an adjuvant of other medicines, and alone as a mild stimulant aromatic tonic. The dose is from one to three fluidounces.—*Note to the twelfth edition.*

of the former to one of the latter. Then moisten the powder with a fluidounce of the mixture, pack it moderately in a conical percolator, and gradually pour the mixture upon it until two pints of filtered liquor are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Cinnamon, in coarse powder, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This tincture has the aromatic and astringent properties of cinnamon, and may be used as an adjuvant to cretaceous mixtures, and astringent infusions or decoctions. The dose is from one to three or four fluidrachms.

Off. Prep. Infusum Digitalis, *U. S.* W.

TINCTURA COCCI. *Br. Tincture of Cochineal.*

"Take of Cochineal, in powder, *two ounces and a half* [avoirdupois]; Proof Spirit *one pint* [Imperial measure]. Macerate for seven days, strain, express, filter, and add sufficient Proof Spirit to make one pint [Imp. meas.]." *Br.*

This is valued chiefly for imparting colour to liquid preparations. It may, however, be given internally in nervous affections in doses varying from twenty drops to a fluidrachm. W.

TINCTURA COLCHICI. *U. S.* Tinctura Colchici Seminis. *Br., U. S.* 1850. *Tincture of Colchicum. Tincture of Colchicum Seed.*

"Take of Colchicum Seed, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a cylindrical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Colchicum Seed, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

It was at one time supposed that the tincture was quite as effective made from the unbruised as the bruised seeds, and corresponding advice was given under Colchici Semen, in the first part of this work; but the opinion has been shown to be erroneous. (*Am. Journ. of Pharm.*, xxvi. 120.) Mr. Maisch recommends, as a convenient method of comminuting the seeds, to macerate them for two or three days in a portion of the menstruum, then to remove them and bruise them in a clean iron mortar; taking care that none of the menstruum or the seeds should be wasted. (*Ibid.*, xxviii. 514.)

This tincture possesses the active properties of colchicum, and may be given whenever that medicine is indicated; but the wine, which contains less alcohol, is generally preferred. The dose is from half a fluidrachm to two fluidrachms. The tincture is sometimes used as an embrocation in rheumatic, gouty, and neuralgic pains. W.

TINCTURA CONII. *U. S.* Tinctura Conii Fructus. *Tincture of Hemlock. Tincture of Hemlock Fruit. Tincture of Conium.*

"Take of Hemlock [leaves], recently dried and in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Hemlock Fruit, and *one Imperial pint* of Proof Spirit, and proceeds as directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

The tincture of hemlock necessarily partakes of the uncertainty of the dried leaves from which it is prepared. There can be little doubt that the tincture of the British Pharmacopœia, made from the recent fruit, is the most efficient. A

preparation made by adding one measure of alcohol to three of the expressed juice, has been used in England under the name of *preserved juice of hemlock*, and has been adopted in the British Pharmacopœia with the title of *Succus Conii* or *Juice of Hemlock*. (See *page* 1384.) The Pharmacopœias have very properly excluded cardamom from the preparation; as it can have little influence upon its medical effects, and tends to obscure the odour which is an indication of the activity of the tincture. A strong odour of conia should be emitted by the tincture upon the addition of potassa. M. Menière states that it lets fall, on standing, a yellow miliary deposit, resembling drops of oil, the form of which is modified under pressure. The dose is from thirty minims to a fluidrachm. W.

TINCTURA CROCI. *Br. Tincture of Saffron.*

The *British Pharmacopœia* takes *one avoirdupois ounce* of Saffron, and *one Imperial pint* of Proof Spirit, and proceeds as directed for the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This tincture possesses all the properties of saffron; but is of little other use than to give colour to mixtures. The dose is from one to three fluidrachms W.

TINCTURA CUBEBÆ. *U. S. Tincture of Cubeb.*

"Take of Cubeb, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

This may be used as a carminative, and has been given with advantage in gonorrhœa in the advanced stages. The late London tincture was nearly three times as strong as the Dublin, and more than twice as strong as the U. S. tincture; but the preparation has been dropped in the British Pharmacopœia. The dose is from half a fluidrachm to two fluidrachms or more, the larger doses being used in gonorrhœal affections. W.

TINCTURA DIGITALIS. *U. S.*, *Br. Tincture of Digitalis. Tincture of Foxglove.*

"Take of Digitalis, recently dried and in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Digitalis, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, p. 1384.)

In preparing this tincture, great attention should be paid to the selection of the leaves, according to the rules laid down under the head of Digitalis. From a neglect of these, it is apt to be weak or inefficient. The expressed juice of the leaves, preserved by means of alcohol, would probably be found a powerful preparation. (See *page* 1383.) The tincture of foxglove possesses all the virtues of that narcotic, and affords a convenient method of administering it, especially in mixtures. It is said by M. Menière to deposit on standing a green oily matter, and some white lance-shaped crystals soluble in an excess of acid. (*Journ. de Pharm.*, Avril, 1861, p. 289.) The dose is from ten to twenty drops, repeated two or three times a day, and increased if necessary, but with caution. W.

TINCTURA ERGOTÆ. *Br. Tincture of Ergot.*

The *British Pharmacopœia* takes *five avoirdupois ounces* of bruised Ergot, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

The dose of this tincture is one or two fluidrachms. W.

TINCTURA FERRI CHLORIDI. *U. S.* TINCTURA FERRI PERCHLORIDI. *Br.* FERRI MURIATIS TINCTURA. *Ed. Tincture of Chloride of Iron. Tincture of Perchloride of Iron. Tincture of Muriate of Iron.*

"Take of Iron, in the form of wire and cut in pieces, *three troyounces;* Muriatic Acid *seventeen troyounces and a half;* Alcohol *three pints;* Nitric Acid, Distilled Water, each, *a sufficient quantity.* Introduce the Iron into a flask of the capacity of two pints, pour upon it eleven troyounces of the Muriatic Acid, and allow the mixture to stand until effervescence has ceased. Then heat it to the boiling point, decant the liquid from the undissolved Iron, filter it through paper, and, having rinsed the flask with a little boiling Distilled Water, add this to it through the filter. Pour the filtered liquid into a capsule of the capacity of four pints, add the remainder of the Muriatic Acid, and, having heated the mixture nearly to the boiling point, add a troyounce and a half of Nitric Acid. When effervescence has ceased, drop in Nitric Acid, constantly stirring, until it no longer produces effervescence. Lastly, when the liquid is cold, add sufficient Distilled Water to make it measure a pint, and mix it with the Alcohol." *U. S.*

"Take of Solution of Perchloride of Iron *five fluidounces;* Rectified Spirit *fifteen fluidounces.* Mix, and preserve in a stoppered bottle. Sp. gr. 0·992. This Tincture has one-fourth the strength of Tinctura Ferri Sesquichloridi, *Dub.*" *Br.*

As directed in the U. S. Pharmacopœia of 1850, this preparation was made with the subcarbonate of iron of the Pharmacopœia, which is a hydrated sesquioxide, containing a small but uncertain proportion of carbonate of the protoxide. This was treated with muriatic acid, which caused some effervescence in consequence of the escape of the carbonic acid of the carbonate, and the result was a solution of the sesquichloride of iron with a little protochloride. As the proportions of subcarbonate and of acid were so arranged in the formula as to leave a slight excess of the former, provided that the acid were duly saturated, there could of course be no excess of acid in the tincture, when completed by the addition of the alcohol. But, in consequence of the presence of a small proportion of protochloride, absorption of oxygen from the air took place, and this protochloride was converted into sesquichloride and sesquioxide of iron, the latter of which, not finding any free muriatic acid to dissolve it, was precipitated. Hence the officinal tincture was apt to deposit a little sesquioxide, with the effect of losing somewhat of its chalybeate strength; and this was an objection to the U. S. formula, though a slight one, as it was easily obviated, if thought advisable, by the addition of a little more of the acid. But there were other difficulties incident to the formula, which led to its frequent partial failure, not only in incompetent hands, but even with skilful pharmaceutists. In the first place, the muriatic acid could not always be obtained of the due officinal strength (sp. gr. 1·16), and this often proved the cause of a comparatively feeble preparation. In the second place, difficulty was often experienced in effecting the solution of the subcarbonate of iron. Properly prepared, and in its recent state, this is easily dissolved in muriatic acid; but it is exceedingly liable to undergo changes, either in its molecular condition, or state of hydration, which impair its solubility, or even render it partially insoluble. The use of heat in preparing or drying it, and the simple influence of time and exposure, have this effect in a greater or less degree; and hence the operator often found great difficulty in dissolving it in the muriatic acid. The consequence was incessant complaints of the imperfection of the formula; and, though these might not be theoretically well founded, as the formula properly executed might yield the due result, yet practically they were so, and it was certainly desirable to have a formula which would be less liable to miscarriage. Accordingly, at the late revision of the U. S. Pharmacopœia, a new process was introduced, in which the objections to the old one appear to be in great measure obviated, though nothing will secure

the operator against failure, who does not take care that the materials he employs are of the proper character.

The present U. S. formula so far imitates that of the late Dublin Pharmacopœia as to prepare directly the necessary sesquichloride by the reaction between muriatic acid and metallic iron; and the proportion of acid and iron is almost the same in both; yet they differ somewhat in the manipulations; and the U. S. formula appears, in respect to the precise method of proceeding, to be copied from that of Dr. Squibb, published in the *Am. Journ. of Pharm.* (July, 1857, p. 290).* Iron wire is chosen as the form of iron to be used because it is generally the purest. This, which is in very slight excess, is first treated with a portion of the muriatic acid which forms with it the protochloride of iron, with the escape of hydrogen, producing effervescence. The action is allowed to go on spontaneously until effervescence ceases, and is then aided by heat, which causes the saturation of the acid used. The solution being filtered, the remainder of the muriatic acid is added, and afterwards the nitric acid gradually, the liquid having been heated to the boiling point before the latter addition. The nitric acid is decomposed, with the escape of nitrous fumes producing effervescence, while through the influence of a portion of its oxygen and the additional portion of muriatic acid, the protochloride is converted into the sesquichloride; the conversion being completed when the effervescence ceases, and the previously green colour has been changed to a reddish-brown. The precise reactions by which these changes are effected have been explained elsewhere. (See *Ferri Chloridum*, page 1127.) The process is completed by adding first enough water to make the measure of a pint, and afterwards the alcohol; thus giving precision to the product. The alcohol reacts gradually with the acid producing a small proportion of muriatic ether, which gives a peculiar flavour to the tincture, and probably modifies in some degree its influence on the system. As the additional quantity of muriatic acid necessary to sesquichloridize the protochloride of iron first formed is just one-half of the quantity of acid first used, that is 5·5 troyounces, and as the amount added is 6·5 ounces, a slight excess of acid must be contemplated in the preparation, which may be useful in preventing precipitation, and in reacting with the alcohol to produce ether.

The British formula consists simply in the mixture of a previously prepared solution of the sesquichloride (*Liquor Ferri Perchloridi*, Br.) with three times its bulk of rectified spirit or alcohol; but as its formula for the solution of the perchloride is defective, the present must be equally so. (See *Liquor Ferri Perchloridi.*) It is intended to make a tincture which shall have the sp. gr. 0·992.

Properties. Tincture of chloride of iron is of a reddish-brown, somewhat yellowish colour, a sour and very styptic taste, and an odour resembling that of muriatic ether. The sesquichloride of iron which it holds in solution, and on which its properties mainly depend, has been described among the preparations of iron. (See *Ferri Chloridum*, page 1126.) According to the U. S. Pharmacopœia, it has the sp. gr. 0·990; and the quantity of sesquioxide of iron which a fluidounce of it will yield, when the precipitate obtained by diluting it with water, and adding ammonia in excess, is washed, dried, and ignited, is 29 grains. The tincture is decomposed by the alkalies, alkaline earths and their carbonates, astringent vegetable infusions, and the mucilage of gum arabic, which produces with it a brown semi-transparent jelly. All these substances are, therefore, incompatible with it in prescriptions.†

* This process of Dr. Squibb was given in a note in the eleventh edition of the U. S. Dispensatory, page 1052.

† *Bestuchef's tincture*, which is much used in Europe, is simply a solution of sesquichloride of iron in a mixture of one measure of ether and three or four measures of alcohol. Fr. Mayer recommends that the sesquichloride should be prepared by passing chlorine through a solution of the protochloride, until a solution of the ferridcyanide of potassium no longer produces a blue precipitate, and then evaporating by a water-bath. In this mode crystals

Medical Properties and Uses. This is one of the most active and certain preparations of iron, usually acceptable to the stomach, and much employed for the purposes to which the chalybeates generally are applied. It has been particularly commended as a tonic in scrofula, in which it was formerly often given, jointly with the solution of chloride of calcium, or chloride of barium. It is supposed to be diuretic, and to have a peculiar influence on the urinary passages. Hence it has been employed in gleet, old gonorrhœa, and leucorrhœa; and is said to be useful in dysury dependent on spasmodic stricture of the urethra, in the dose of ten drops repeated every ten minutes, till some effect is experienced. In hemorrhages from the uterus, kidneys, and bladder, it is thought to act advantageously, but should be confined to those of a passive character, or employed only after sufficient depletion. Upon the recommendation of Dr. Bell, of Edinburgh, it has recently been much employed in erysipelas, with great supposed advantage; and, upon the same principle, that of improving the condition of the blood, has been used in various other diseases, as scarlatina, diphtheria, and purulent infection of the blood. Externally it is sometimes used for the destruction of venereal warts, and as a styptic in cancerous and fungous ulcers. It has recently been employed, with success, as an injection in aneurismal tumours. (See *Ranking's Abstract*, xviii. 120.) The dose of the U. S. tincture is from ten to thirty minims, which may be gradually increased to one or even two fluidrachms, two or three times a day. In acute febrile diseases, as erysipelas, the dose should be repeated every two hours. It is given diluted with water. W.

TINCTURA GALLÆ. *U. S.*, *Br.* *Tincture of Nutgall. Tincture of Galls.*

"Take of Nutgall, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a glass percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Galls, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

The tincture of galls is powerfully astringent; but is more used as a test than as a medicine. When long kept it ceases to evince the reactions of tannic acid, in consequence of the conversion of this into gallic acid. The dose is from one to three fluidrachms. W.

TINCTURA GENTIANÆ COMPOSITA. *U. S.*, *Br.* *Compound Tincture of Gentian.*

"Take of Gentian, in moderately fine powder, *two troyounces;* Bitter Orange Peel, in moderately fine powder, *a troyounce;* Cardamom, in moderately fine powder, *half a troyounce;* Diluted Alcohol *a sufficient quantity.* Mix the

of the sesquichloride are obtained, one ounce of which is to be dissolved in twelve ounces of ether, mixed with four times its bulk of alcohol. The solution may be rendered colourless, if desired, by exposure to the direct rays of the sun. (*N. Y. Journ. of Pharm.*, i. 233.) This decolorization, however, is effected by a chemical change which somewhat alters the character of the preparation. The sesquichloride becomes protochloride by the loss of a portion of its chlorine, which, by abstracting hydrogen from the alcohol, becomes muriatic acid; and this reacts with unaltered alcohol to form muriatic ether.

Mr. A. Cushman recommends the following process for the above tincture. He first prepares the crystals of the sesquichloride by dissolving two ounces of iron filings in a mixture of eight fluidounces of muriatic acid and four of distilled water, then adding four fluidrachms of nitric acid, evaporating to a pellicle, and setting aside to crystallize. The crystals, having been washed in alcohol, and afterwards redissolved and crystallized, are to be dissolved in a mixture of two parts of alcohol and one of ether; the proportion being an ounce of the crystals to twelve fluidounces of the mixture. After solution, the liquid is to be filtered, and exposed for 48 hours to the direct rays of the sun. (*Am. Journ. of Pharm.*, xxix. 461, from *Am. Med. Gaz.*)—*Note to the eleventh edition.*

powders, and, having moistened the mixture with a fluidounce and a half of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *one and a half avoirdupois ounces* of bruised Gentian, *three-quarters of an avoird. ounce* of Bitter Orange Peel, cut small and bruised, *a quarter of an avoird. ounce* of bruised Cardamoms, and *one Imperial pint* of Proof Spirit, and proceeds with these ingredients in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This is an elegant bitter, much used in dyspepsia, and as an addition to tonic mixtures in debilitated states of the digestive organs, or of the system generally. There is, however, much danger of its abuse, especially in chronic cases. The dose is one or two fluidrachms. W.

TINCTURA GUAIACI. *U. S. Tincture of Guaiac.*

"Take of Guaiac, in moderately coarse powder, *six troyounces;* Alcohol *a sufficient quantity.* Mix the powder thoroughly with an equal bulk of dry sand, pack the mixture moderately in a conical percolator, and, having covered it with a layer of sand, gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

This tincture is given in chronic rheumatism and gout, in the dose of from one to three fluidrachms three or four times a day. As it is decomposed by water, it is most conveniently administered in mucilage, sweetened water, or milk, by which the separated guaiac is held in temporary suspension. The following is a form of tincture of guaiac which the late Dr. Dewees found very efficient in the cure of suppression of the menses and dysmenorrhœa. "Take of the best Guaiac, in powder, *four ounces;* Carbonate of Soda or of Potassa *one drachm and a half;* Pimento, in powder, *an ounce;* Diluted Alcohol *a pound.* Digest for a few days." Dr. Dewees directed a drachm or two of the spirit of ammonia to be added, "*pro re nata,*" to four fluidounces of the tincture. (*Treat. on Diseases of Females*, A. D. 1826, p. 81.) The dose is a teaspoonful three times a day, to be gradually increased if necessary. Within our own experience, this remedy has seemed highly useful in painful menstruation, given in the intervals of the attacks. The quantity of alkaline addition is too small to produce any sensible effect, and the pimento can act only as a spice; so that the virtues of the tincture reside in the guaiac, and the officinal tincture would probably be found equally effectual. W.

TINCTURA GUAIACI AMMONIATA. *U. S.*, *Br.* TINCTURA GUAIACI COMPOSITA. *Lond. Ammoniated Tincture of Guaiac.*

"Take of Guaiac, in moderately coarse powder, *six troyounces;* Aromatic Spirit of Ammonia *two pints.* Macerate for seven days, and filter through paper." *U. S.*

"Take of Guaiac Resin, in fine powder, *four ounces* [avoirdupois]; Aromatic Spirit of Ammonia *one pint* [Imperial measure]. Macerate for seven days in a well-closed vessel and filter, then add sufficient Aromatic Spirit of Ammonia to make one pint [Imp. meas.]." *Br.*

This tincture is celebrated in the treatment of chronic rheumatism, and is frequently also used in amenorrhœa. It is more stimulating, and is thought to be more effectual than the preceding. Like that, it is decomposed by water, and should be administered in some viscid or tenacious vehicle which may hold the guaiac in suspension. The dose is one or two fluidrachms. W.

TINCTURA HELLEBORI. *U. S. Tincture of Black Hellebore.*

"Take of Black Hellebore, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a cylindrical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

This tincture, formerly called *tinctura Melampodii*, possesses the properties of black hellebore, and, upon the recommendation of Dr. Mead, has been much used in suppression of the menses. It is said to be peculiarly applicable to cases in which the grade of action is too high for the use of chalybeates. At best, however, it is an uncertain remedy, and, though frequently almost inert from the bad quality of the root, should always be administered with caution, as it is sometimes violent in its action. The dose is from thirty minims to a fluidrachm, to be taken night and morning. W.

TINCTURA HUMULI. *U. S.* TINCTURA LUPULI. *Br.* *Tincture of Hops.*

"Take of Hops, in moderately coarse powder, *five troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it very firmly in a cylindrical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Hops, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

Hops are so light and bulky that, in the proportion directed, and as prepared by the U. S. process of 1850, they absorbed almost all the spirit, which, after the requisite maceration, could be separated only by strong pressure. As this absorption of the spirit obstructed its proper action on the hops, it was necessary that the mixture should be frequently stirred during the maceration. This remark is not applicable to the present U. S. process, but continues so to that of the Br. Pharmacopœia. By thoroughly drying the hops and rubbing them between the hands, or by cutting and bruising them, they may be brought to a state of division which will in a great measure obviate the disadvantages alluded to. As the virtues of hops depend chiefly on the lupulin, and as the quantity of this substance is different in different parcels, the tincture is necessarily unequal in strength; and the tincture of lupulin itself is preferable. (See *Tinctura Lupulinæ.*) According to *M. Menière* tincture of hops deposits, on standing, a yellow precipitate, and a large quantity of a white crystalline substance, which he thinks may be malate of lime.

Tincture of hops is tonic and narcotic, and has been proposed as a substitute for laudanum when the latter disagrees with the patient; but little reliance can be placed upon it. The condition of disease to which it appears to be best adapted, is the wakefulness, attended with tremors and general nervous derangement, to which habitual drunkards are liable, and which frequently precedes an attack of delirium tremens. The dose is from one to three fluidrachms. W.

TINCTURA HYOSCYAMI. *U. S., Br.* *Tincture of Henbane. Tincture of Hyoscyamus.*

"Take of Henbane Leaf, in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Hyoscyamus Leaves, dried and bruised, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This tincture may be advantageously substituted, as an anodyne and soporific, for that of opium, when the latter disagrees with the patient, or is objectionable on account of its property of inducing constipation. When the tincture of henbane purges, as it sometimes does, it may be united with a very small proportion of laudanum. The dose is a fluidrachm. The expressed juice preserved by means of alcohol may be used for the same purposes as the tincture. W.

TINCTURA IODINII. *U. S. Tincture of Iodine.*

"Take of Iodine *a troyounce;* Alcohol *a pint.* Dissolve the Iodine in the Alcohol." *U. S.*

This tincture has very nearly the strength of the tincture of Coindet, which contained one part of iodine to twelve of alcohol by weight; while the U. S. tincture contains one part of the former to about 12·7 parts of the latter. It is best to prepare the tincture in small quantities at a time; as the iodine reacts with the alcohol, especially when exposed to solar light, giving rise to chemical changes. The iodine should be thoroughly dried before being weighed out. The tincture should be kept in well-stopped bottles, in order to prevent the evaporation of the alcohol, and the consequent crystallization of the iodine.

The tincture of iodine has a deep-brown colour. Sixteen minims, equal to about thirty-five drops, contain one grain of iodine. It is at present less used internally than it formerly was, in consequence of an impression that it is apt to irritate the stomach. Water decomposes the tincture, and, when this is swallowed, it is supposed that the iodine is precipitated upon the mucous membrane. Besides, the tincture undergoes a gradual change when kept, owing, according to Guibourt, to a reaction between the alcohol and iodine. A portion of the latter is supposed to take hydrogen from the former, producing hydriodic acid, which combines with another portion of the iodine to form iodurettted hydriodic acid; while the place of the hydrogen in the alcohol is thought to be supplied by iodine, giving rise to another iodurettted compound. The new products are soluble in water; and consequently the tincture gradually loses by time the property of being precipitated on dilution. (*Journ. de Pharm.*, 3*e sér.*, x. 113.) Yet, from the experiments of Dr. A. Göpel, it would appear that the change is slow if the tincture is kept in the dark and at a low temperature; for in three months a specimen thus treated had lost but one per cent. of iodine. (*Pharm. Central Blatt*, No. 13, A. D. 1850.) On account of its liability to precipitation in the stomach, the tincture of iodine is now almost exclusively employed locally. Undiluted, it acts as a powerful irritant to the skin, producing inflammation, desquamation of the cuticle, &c. Nevertheless, it is much used in this state in erysipelas, chilblains, and other cases of cutaneous and subcutaneous inflammation, and with happy effects. But its application requires some caution; and, in erysipelas, we are in the habit rather of surrounding the inflamed surface with a border of the tincture, embracing a portion of both the sound and the diseased skin, so as to prevent the progress of the inflammation, than of attempting a complete cure by covering the whole surface affected. It has been found useful in rendering the variolous eruption abortive. It has also been employed externally in croup, the bites of serpents, and local rheumatism. It is most conveniently applied by means of a camel's hair pencil. Diluted with camphorated tincture of soap, or other alcoholic liquid, it is sometimes employed as an embrocation in scrofulous tumours and other affections requiring the use of iodine. It is much used in the radical cure of hydrocele, as an injection into the sac; and a similar employment of it has been extended to other serous cavities morbidly distended with fluid, as in ovarian dropsy, ascites, and empyema; but in these latter affections it should be resorted to, if at all, with great caution. In hydrocele, M. Velpeau employed it diluted with double its volume of water. In the other cases referred to, it has been variously diluted with from three to ten times its bulk of water, or some demulcent liquid. To prevent the precipitation of the iodine, iodide of potassium is generally added in the proportion of from two scruples to a drachm to each fluidounce of the tincture.

The dose of the tincture is from ten to twenty drops, which may be gradually increased to thirty or forty drops, three times a day. It may be given in sweetened water, and still better in wine, when this is not contraindicated. M. Debauque, an apothecary of Mons, has ascertained that tannic acid has the property

of rendering iodine soluble in water, and states that an ounce of syrup of orange peel, in four or six ounces of water, will form a clear solution with a quantity of tincture of iodine containing five or six grains of the medicine. (*Journ. de Pharm.*, 3e sér., xx. 34.) W.

TINCTURA IODINII COMPOSITA. *U. S.* TINCTURA IODI. *Br.* *Compound Tincture of Iodine.*

"Take of Iodine *half a troyounce;* Iodide of Potassium *a troyounce:* Alcohol *a pint.* Dissolve the Iodine and Iodide of Potassium in the Alcohol." *U. S.*

"Take of Iodine *half an ounce* [avoirdupois]; Iodide of Potassium *a quarter of an ounce* [avoird.]; Rectified Spirit *one pint* [Imperial measure]. Dissolve the Iodine and the Iodide of Potassium in the Spirit." *Br.*

The U. S. tincture is rather stronger than the British, the troyounce being heavier than the avoirdupois; while the wine pint employed in the former contains about one-fifth less than the Imperial pint employed in the latter. The difference, however, is of no great practical importance. The advantage of this tincture over the simple tincture above described is, that the former may be diluted with water without decomposition; so that, when it is swallowed, iodine is not precipitated upon the mucous coat of the stomach, and will not, therefore, be so likely to produce gastric irritation. This is a good theoretical recommendation; but we are by no means confident that the difference of the two preparations in irritating properties will be found very striking in practice. The compound tincture of iodine may be given internally for all the purposes which iodine is capable of answering. The dose is from fifteen to thirty drops, to be gradually increased if necessary. W.

TINCTURA JALAPÆ. *U. S., Br.* *Tincture of Jalap.*

"Take of Jalap, in fine powder, *six troyounces;* Alcohol, Water, each, *a sufficient quantity.* Mix two measures of Alcohol with one of Water. Then moisten the powder with *two fluidounces* of the mixture, pack it moderately in a cylindrical percolator, and gradually pour the mixture upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Jalap, in coarse powder, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, p 1384.)

In the present U. S. process the alcoholic strength of the menstruum has been considerably increased, which is an improvement in view of the resinous character of the purgative principle of jalap. The tincture possesses the medical virtues of jalap, and is sometimes added to cathartic mixtures in the quantity of one or two fluidrachms, to increase their activity. W.

TINCTURA KINO. *U. S., Br.* *Tincture of Kino.*

"Take of Kino, in fine powder, *three hundred and sixty grains:* Alcohol, Water, each, *a sufficient quantity.* Mix two measures of Alcohol with one of Water. Then mix the powder thoroughly with an equal bulk of dry sand, and, having introduced the mixture into a conical glass percolator, gradually pour the menstruum upon it until half a pint of tincture is obtained." *U. S.*

"Take of Kino, in moderately fine powder, *two ounces* [avoirdupois]; Rectified Spirit *one pint* [Imperial measure]. Macerate for seven days, filter, and add sufficient Rectified Spirit to make one pint [Imp. meas.]." *Br.*

When maceration is employed, a good plan is to suspend the kino, confined in a bag, in the menstruum; as, when allowed to stand, in the ordinary method, the powder is apt to agglutinate, and adhere to the sides and bottom of the bottle. The tincture very frequently becomes gelatinous if kept, and at length almost entirely loses its astringency. The character of the chemical reaction which takes place remains to be investigated. The air has some effect; for if this is entirely excluded the tincture keeps for a long time without undergoing the change. The

apothecary should introduce it, when prepared, into very small bottles, which should be kept well corked, and only opened when wanted for use. It is in consequence of its tendency to gelatinize, that the U. S. Pharmacopœia directs it to be frequently renewed. The dose is one or two fluidrachms. It is used chiefly as an addition to cretaceous and other astringent mixtures in diarrhœa.* W.

TINCTURA KRAMERIÆ. *U. S., Br. Tincture of Rhatany.*

"Take of Rhatany, in moderately fine powder, *six troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it in a cylindrical glass percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Rhatany, and *one Imperial pint* of Proof Spirit, and proceeds as directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

According to F. Boudet, the tincture of rhatany sometimes gelatinizes like that of kino (*Journ. de Pharm.*, 3*e sér.*, i. 338); and the same observation has been made by others. The same precaution, therefore, should be observed, in relation to the mode of keeping it, as recommended in reference to tincture of kino. This is a good preparation of rhatany in cases which admit of the use of small quantities of alcohol. The dose is one or two fluidrachms. W.

TINCTURA LIMONIS. *Br. Tincture of Lemon Peel.*

The *British Pharmacopœia* prepares this Tincture in the same manner as Tincture of Aconite Root, using *two and a half avoirdupois ounces* of fresh Lemon Peel, "sliced thin," and *one Imperial pint* of Proof Spirit. (See *Tinctura Aconiti*, page 1384.)

This tincture forms a grateful aromatic addition to tonic and purgative infusions, mixtures, &c. It may be used in the dose of one or two fluidrachms. W.

TINCTURA LOBELIÆ. *U. S., Br. Tincture of Lobelia.*

"Take of Lobelia, in fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Diluted Alcohol, pack it firmly in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* prepares this Tincture from *two and a half avoirdupois ounces* of Lobelia, dried and bruised, and *one Imperial pint* of Proof Spirit, in the same manner as Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This tincture possesses the emetic and narcotic properties of lobelia, and is much used in asthma, in the dose of one or two fluidrachms, repeated every two or three hours till its effects are experienced. The emetic dose is half a fluidounce. A saturated tincture is strongly recommended by Dr. A. Livezey, as a local application in erysipelas, and the external poisonous effect of Rhus Toxicodendron. (*Bost. Med. and Surg. Journ.*, lv. 262.) W.

TINCTURA LOBELIÆ ÆTHEREA. *Br. Ethereal Tincture of Lobelia.*

"Take of Lobelia, dried and bruised, *two ounces and a half* [avoirdupois];

* We have received the following letter, which speaks for itself, and for which we owe our thanks to the writer.

"Louisville, Ky., June 14, 1864. *Dear Sir,*—I transmit you herewith a process for preparing Tr. Kino, which will not gelatinize, and appears to retain its qualities unimpaired. Take of Kino *one ounce and a half;* Ground Logwood *half an ounce;* Diluted Alcohol *a sufficient quantity.* Moisten the Logwood with a portion of the Diluted Alcohol, and introduce it into a displacement apparatus. Dissolve the Kino by triturating with successive portions of Dil. Alcohol, and percolate the solution through the Logwood until a pint of tincture is obtained. Yours, &c., P. F. Smith."

Spirit of Ether *one pint* [Imperial measure]. Macerate for seven days, then press and strain, and add sufficient Spirit of Ether to make one pint [Imp. meas.]." *Br.*

The stimulant operation of the ether in this preparation can scarcely favour the relaxing and nauseating action for which lobelia is usually employed. The dose is the same as that of the alcoholic tincture. W.

TINCTURA LUPULINÆ. *U. S. Tincture of Lupulin.*

"Take of Lupulin *four troyounces;* Alcohol *a sufficient quantity.* Pack the Lupulin in a narrow cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

This is much superior to the tincture of hops of the first U. S. Pharmacopœia, in the place of which it was introduced into the second edition. In the original preparation, a certain quantity of hops was directed, from which the lupulin was to be separated by beating, and then digested in alcohol. As hops contain a variable proportion of lupulin, the tincture thus made must be of unequal strength; an objection to which the tincture of hops, even as now prepared, is in some measure liable. Besides, the amount of lupulin, contained in any quantity of hops upon which alcohol can conveniently act, is too small in proportion to the alcohol, to afford a tincture of the due strength. The tincture of lupulin is, therefore, greatly preferable. The dose is one or two fluidrachms, to be given in sweetened water or some mucilaginous fluid. W.

TINCTURA MYRRHÆ. *U. S., Br. Tincture of Myrrh.*

"Take of Myrrh, in moderately coarse powder, *three troyounces;* Alcohol *a sufficient quantity.* Introduce the powder into a conical percolator, press it moderately, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of Myrrh, in coarse powder, and *one Imperial pint* of Rectified Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

Officinal alcohol is preferable, as a solvent of myrrh, to that fluid mixed with water; because it forms a perfectly clear solution, which is not attainable with the latter menstruum. The addition of water to the tincture renders it turbid. The tincture of myrrh is scarcely ever used internally. As a local application it is employed to stimulate indolent and foul ulcers, and promote the exfoliation of bones, and, diluted with water, is applied to spongy gums, aphthous sore-mouth, and ulcerations of the throat. The dose, as a stimulant expectorant and emmenagogue, is from thirty minims to a fluidrachm.

Off. Prep. Tinctura Aloës et Myrrhæ. W.

TINCTURA NUCIS VOMICÆ. *U. S., Br. Tincture of Nux Vomica.*

"Take of Nux Vomica, in fine powder, *eight troyounces;* Alcohol *a sufficient quantity.* Mix the powder with a pint of Alcohol, and digest for twenty-four hours, in a close vessel, with a gentle heat; then transfer the mixture to a cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two avoirdupois ounces* of Nux Vomica, and *one Imperial pint* of Rectified Spirit, and, having softened by steam, quickly dried, and then powdered the Nux Vomica, proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

It is of the greatest importance, in this process, that the nux vomica should be well powdered; and, in consequence of the difficult action of solvents on this substance, probably from the presence of bassorin, a preliminary digestion is desirable. The tincture is not an eligible form for administering nux vomica; as it is equally uncertain with the medicine in substance, and has the disadvantage of

excessive bitterness. The alcoholic extract, or strychnia, is preferable. The dose of the tincture is twenty minims, to be increased if necessary. It is sometimes employed externally, in cases of local paralysis. W.

TINCTURA OPII. *U. S., Br. Tincture of Opium. Laudanum.*

"Take of Opium, dried, and in moderately fine powder, *two troyounces and a half;* Water, Alcohol, each, *a pint;* Diluted Alcohol *a sufficient quantity.* Macerate the Opium with the Water for three days, with frequent agitation; then add the Alcohol, and continue the maceration for three days longer. Introduce the mixture into a percolator, and, when the liquid has ceased to pass, pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

"Take of Opium, in coarse powder, *one ounce and a half* [avoirdupois]; Proof Spirit *one pint* [Imperial measure]. Macerate the Opium for seven days, strain, express, and filter; then add sufficient Proof Spirit to make one pint [Imp. meas.]." *Br.*

The proportion of opium in these formulas is so nearly the same that the resulting tinctures may be considered identical. The apparent difference between the British formula and ours will vanish, when the relative value of the avoirdupois weight and Imperial measure, which they employ, and of the troy weight and wine measure of our Pharmacopœia is estimated. The drying and powdering of the opium is clearly a useful provision; as it ensures greater uniformity in the strength of the tincture. Crude opium contains variable proportions of water; and laudanum prepared from a moist specimen will be weaker than that from an equal weight of the dried. The pulverization ensures the previous drying of the drug, and is thus useful independently of the greater facility which it gives to the action of the menstruum. It is troublesome, however, and is often neglected. Innovation in so important a preparation, and one in which uniformity is so desirable, should be avoided, unless shown to be necessary. There can be little doubt, we think, that the present somewhat elaborate method of the U. S. formula ensures a more complete exhaustion of the opium than the former simple procedure of maceration for two weeks, and still more so than the British process, which macerates for only one week.

In the United States and Great Britain, this tincture is universally known by the name of *laudanum.* As this term was formerly applied to other preparations of opium, and still continues to be so on the continent of Europe, the tincture is sometimes distinguished by the epithet *liquidum,* which, however, is seldom used in this country. *Tinctura Thebaica* is another title by which the preparation is known.

About two-thirds of the opium used in the preparation of the tincture are dissolved, the residue consisting chiefly of inert matter. Allowing the opium to be wholly exhausted of its active principles, one grain would be represented by 12·8 minims, according to the U. S. formula; but a minute quantity of morphia has been detected in the residuary matter, so that the tincture is rather weaker than the proportion of opium employed would indicate. The difference, however, is insufficient to be of any practical importance.

The tincture of opium is used for all the purposes to which opium itself is applied. (See *Opium.*) The dose, equivalent to a grain of opium, is about thirteen minims, or twenty-five drops. Mr. Phillips, in his translation of the London Pharmacopœia of 1836, states that, by evaporating the tincture, and also by determining the quantity of opium left undissolved, he found the preparation to contain one grain of opium in 19 minims; and this quantity, therefore, is given as the dose equivalent to a grain of opium. But this mode of calculation is obviously fallacious; as the portion of the drug dissolved is much more active than that left behind by the menstruum. Indeed, so feeble is the latter, that Dr. Garrod gave thirty grains of the residue to a healthy adult without effect. (*Pharm. Journ.*, xi. 252.) It should be recollected that a fluidrachm or tea-

spoonful of laudanum (60 minims) will yield, on an average, about 120 drops. Laudanum when long kept, with occasional exposure to the air, becomes thick from the evaporation of a portion of the alcohol, and the deposition of opium. If given in this state, it often acts with unexpected energy; and death has resulted in infants from its use in doses which would have been entirely safe if the tincture had been clear.

Denarcotized laudanum may be prepared by substituting the extract of opium in half the quantity for the opium itself, and, previously to the maceration in diluted alcohol, exhausting it of the narcotina by ether.*

Off. Prep. Enema Opii, *Br.;* Linimentum Opii, *Br.* W.

TINCTURA OPII ACETATA. *U.S. Acetated Tincture of Opium.*

"Take of Opium, dried, and in moderately fine powder, *two troyounces;* Vinegar *twelve fluidounces;* Alcohol *half a pint.* Rub the Opium with the Vinegar; then add the Alcohol, and, having macerated for seven days, express, and filter through paper." *U. S.*

This preparation was introduced into the second edition of our Pharmacopœia as a substitute for the *Acetum Opii* or *black drop* of the original work, the advantages of which it was supposed to possess, without being liable to the same objection of uncertainty of strength. The Acetum Opii, however, having maintained its standing in the estimation of the profession, and of the public,

* *Elixir of Opium.* Under this name have been sold different liquid preparations of opium, consisting mainly, in all probability, of an aqueous solution, with sufficient alcohol to preserve it. A formula of this kind was published by Mr. Eugene Dupuy, of New York, in the *Am. Journ. of Pharm.* (xxiii. 211). Professor Procter in the same place gave a formula, differing from that of Mr. Dupuy in the employment of ether, so as to obtain at one operation a preparation analogous to the denarcotized laudanum mentioned in the text. This formula of Prof. Procter has been adopted, with some slight change, in the present edition of the U. S. Pharmacopœia, under the title of *Tinctura Opii Deodorata*, which will be found in the text.

Since the publication of the eleventh edition of the U. S. Dispensatory, the supposed composition of the nostrum, long noted and much used under the name of *McMunn's Elixir of Opium*, has been published in the *Medical and Surgical Reporter* of this city: the formula having been furnished to that journal as found among the papers of the late Dr. Chilton, of New York, who is supposed to have received it from the proprietor. The following is an abstract of the formula. Five pounds of opium were first exhausted by ether of everything soluble in that menstruum, including the narcotina and the odorous principle. The drug was then introduced into water heated short of the boiling point, which caused a strong ebullition through the escape of the ether remaining in the mass. After the expulsion of the ether, it was macerated to exhaustion with water sufficient to make, when strained, four gallons of infusion; and if the quantity fell short of this, enough boiling water was added to complete the measure. After standing for five or six days in a cool cellar, the clear liquor was removed, and, the residue having been filtered, was mixed with the filtrate. To the four gallons of watery infusion thus prepared five and a half gallons of alcohol were added, and the mixture set aside for a few days, when the clear part was ladled out and the dregs filtered as before. The strength was intended to be the same as that of laudanum. (See *Am. Journ. of Pharm.*, May, 1864, p. 262.)

In the same journal (March, 1860, p. 120) Dr. Squibb published the formula of what he denominates "*Liquor Opii Compositus*," of which the outline is, *first*, the exhaustion of the opium with water; *secondly*, after concentration of the infusion, the addition of alcohol so as to dissolve everything soluble in that liquid; *thirdly*, after concentration of the clear alcoholic solution, the washing of the residue with ether, the ethereal washings being rejected; *fourthly*, the solution of the washed extract in water, with subsequent filtration; *fifthly*, the assaying of the watery solution to ascertain the proportion of morphia; and *lastly*, adding to the solution so much compound spirit of ether (Hoffmann's anodyne) as to make each fluidounce of the resulting compound solution of opium contain four grains of morphia and fifty-six grains of the compound spirit of ether, representing the average morphia strength of the officinal tincture of opium. For particulars the reader is referred to the communication of Dr. Squibb, in the above-mentioned journal. Most of these extra-officinal preparations of opium will probably be superseded by the excellent officinal introduced into the present edition of our Pharmacopœia, under the name of *Tinctura Opii Deodorata.—Note to the twelfth edition.*

was restored, in the edition of 1840, to its officinal rank, but so modified as to ensure a preparation as uniform as is consistent with the variable quality of the opium used. (See *page* 913.) At the same time the formula for the acetated tincture was retained, as affording a useful preparation. It was originally employed by the late Dr. Joseph Hartshorne, of Philadelphia.

The acetated tincture of opium may often be advantageously used in cases in which laudanum or opium itself produces unpleasant effects, such as nausea and vomiting, intense headache, great nervous disorder, &c.; but the introduction of the salts of morphia into use has in a great measure superseded the necessity of this preparation. The dose is ten minims, or about twenty drops, equivalent to a grain of opium. W.

TINCTURA OPII CAMPHORATA. *U. S.* Tinctura Camphoræ cum Opio. *Br. Camphorated Tincture of Opium. Paregoric Elixir.*

"Take of Opium, dried, and in moderately fine powder, Benzoic Acid, each, *sixty grains;* Camphor *forty grains;* Oil of Anise *a fluidrachm;* Clarified Honey *two troyounces;* Diluted Alcohol *two pints.* Macerate for seven days, and filter through paper." *U. S.*

"Take of Opium, in coarse powder, *forty grains;* Benzoic Acid *forty grains;* Camphor *thirty grains;* Oil of Anise *half a fluidrachm;* Proof Spirit *one pint* [Imperial measure]. Macerate for seven days, strain, express, and filter, then add sufficient Proof Spirit to make one pint [Imp. meas.]." *Br.*

This is the well-known *paregoric elixir.* It is a very pleasant anodyne and antispasmodic, much used to allay cough in chronic catarrh, asthma, consumption, pertussis, &c.; to relieve nausea and slight pains in the stomach and bowels; to check diarrhœa; and, in infantile cases, to procure sleep. Half a fluidounce of the U. S. and British tincture contains rather less than a grain of opium. Liquorice, which was directed in a former edition of the U. S. Pharmacopœia, was omitted in that of 1840, in consequence of giving to the preparation the dark colour of laudanum, and thus leading to mistake. The dose for an infant is from five to twenty drops, for an adult from one to two fluidrachms.*

Off. Prep. Mistura Glycyrrhizæ Composita, *U. S.* W.

TINCTURA OPII DEODORATA. *U. S. Deodorized Tincture of Opium.*

"Take of Opium, dried, and in moderately fine powder, *two troyounces and a half;* Ether, Alcohol, each, *half a pint;* Water *a sufficient quantity.* Ma-

* The following formulas have been adopted by the Philadelphia College of Pharmacy for the preparation of the two compound tinctures of opium, so much used under the names of *Bateman's drops* and *Godfrey's cordial.* So long as these nostrums are employed, it is important that they should be prepared in a uniform manner, and of a certain strength; as serious consequences may happen from diversity in the formulas, when so active a substance as opium is the chief ingredient. Such diversity has existed to a very great extent: so much so that in one formula for Bateman's drops the quantity of opium was seven and a half grains to the pint, while in another it exceeded one hundred grains. It was in order to remedy this evil that the College was induced to adopt the formulas here presented.

"*Bateman's pectoral drops.* Take of Diluted Alcohol Cong. iv, Red Saunders, rasped, ℥ij. Digest for twenty-four hours, filter, and add of Opium, in powder, ℥ij, Catechu, in powder, ℥ij, Camphor ℥ij, Oil of Anise f℥iv. Digest for ten days." This preparation is about equal in strength to the camphorated tincture of opium or paregoric elixir of the U. S. Pharmacopœia, containing about two grains of opium to the fluidounce.

"*Godfrey's cordial.* Take of Tincture of Opium Oiss, Molasses (from the sugar refiners) Oxvj, Alcohol Oij, Water Oxxvj, Carbonate of Potassa ℥iiss, Oil of Sassafras f℥iv. Dissolve the Carbonate of Potassa in the Water, add the Molasses, and heat over a gentle fire till they simmer; take off the scum which rises, and add the Laudanum, Alcohol, and Oil of Sassafras, having previously mixed them well together." This preparation contains the strength of rather more than one grain of opium in a fluidounce. (*Journ. of the Phil. Col. of Pharm.*, v. 26 and 27.)

cerate the Opium with half a pint of Water for twenty-four hours, and express; then repeat the operation twice with the same quantity of Water. Mix the expressed liquids, and, having evaporated the mixture to four fluidounces, shake it when cold, in a bottle, repeatedly with the Ether. Pour off the ethereal solution when it has separated by standing, and evaporate the remaining liquid until all traces of ether have disappeared. Mix this with twenty fluidounces of Water, and filter the mixture through paper. When the liquid has ceased to pass, add sufficient Water, through the filter, to make the filtered liquid measure a pint and a half. Lastly, add the Alcohol, and mix them together." *U. S.*

This is an excellent preparation of opium, calculated to supersede various extra-officinal *elixirs* or *solutions*, which have had more or less vogue, based upon the real advantages they afforded, in offering liquid preparations of opium exempt from certain noxious ingredients in the crude drug and in the officinal tinctures, which rendered them so offensive to some constitutions, and in some conditions of disease, as almost to forbid their use. A liquid watery extract is first made, in which are left behind all the ingredients of opium soluble in alcohol and not in water; and this being well shaken with ether, is further deprived of all the principles soluble in this fluid, including narcotina, and the noxious odorous matter, which is probably one of the most offensive and least useful constituents of opium. The ether is then entirely separated, and the residue having been dissolved in water, the solution is filtered, and mixed with enough alcohol to preserve it. The name is, we think, unfortunate, as the preparation is really not a tincture; the alcohol being used in no degree as a menstruum, but only in reference to its preservative influence. We should have preferred *Infusum Opii Deodoratum*, or some other title expressive of the fact that it is effectively a watery solution of an extract of opium, deprived of the odorous and other injurious ingredients of that drug. It may be used in all cases in which laudanum is indicated, but in which it cannot be used in consequence of idiosyncrasy of the patient, or peculiarity in the disease. The dose is the same as that of the officinal tincture of opium. W.

TINCTURA QUASSIÆ. *U. S. Tincture of Quassia.*

"Take of Quassia, in moderately fine powder, *two troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

This tincture has been omitted in the British Pharmacopœia.

In the edition of the U. S. Pharmacopœia of 1840, the proportion of the quassia to the menstruum was very judiciously doubled. A tonic tincture can scarcely contain too large a proportion of the active ingredient. The tincture may be employed as an addition to tonic infusions or mixtures in the dose of one or two fluidrachms. It is a pure and intense bitter. W.

TINCTURA QUINIÆ COMPOSITA. *Br. Compound Tincture of Quinia.*

"Take of Sulphate of Quinia *one hundred and sixty grains;* Tincture of Orange Peel *one pint* [Imperial measure]. Digest for seven days, and strain." *Br.*

A fluidrachm of this preparation, containing a grain of sulphate of quinia, may be given for a dose. W.

TINCTURA RHEI. *U. S., Br. Tincture of Rhubarb.*

"Take of Rhubarb, in moderately coarse powder, *three troyounces;* Cardamom, in moderately fine powder, *half a troyounce;* Diluted Alcohol *a sufficient quantity.* Mix the powder, and, having moistened the mixture with a fluidounce of Diluted Alcohol, pack it moderately in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes of bruised Rhubarb *two avoirdupois ounces;* of bruised Cardamoms, of bruised Coriander, and of Saffron, each, *a quarter of an avoirdupois ounce,* and *one Imperial pint* of Proof Spirit; and with these ingredients proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti,* page 1384.)

TINCTURA RHEI ET ALOES. *U. S.* 1850, *Ed. Tincture of Rhubarb and Aloes.* ELIXIR SACRUM. *Sacred Elixir.*

"Take of Rhubarb, bruised, *ten drachms;* Aloes, in powder, *six drachms;* Cardamom [seeds], bruised, *half an ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper." *U. S.* 1850.

The *Ed. College* took *a troyounce and a half* of Rhubarb, *six drachms* of Socotrine or E. India Aloes, both in moderately fine powder, *five drachms* of bruised Cardamom seeds, and *two Imperial pints* of Proof Spirit, moistened the solid materials with a little of the Spirit, and, having allowed the mass to stand for ten or twelve hours, packed it in a percolator, and poured on the remainder of the Spirit.

TINCTURA RHEI ET GENTIANÆ. *U. S.* 1850, *Ed. Tincture of Rhubarb and Gentian.*

"Take of Rhubarb, bruised, *two* [*troy*]*ounces;* Gentian, bruised, *half a* [*troy*] *ounce;* Diluted Alcohol *two pints.* Macerate for fourteen days, express, and filter through paper." *U. S.* 1850.

The *Ed. College* took *two troyounces* of Rhubarb, in moderately fine powder, *half a troyounce* of Gentian, finely cut or in coarse powder, and *two Imperial pints* of Proof Spirit, and proceeded in the same manner as above indicated for Tincture of Rhubarb and Aloes.

The foregoing tinctures of Rhubarb, of which the first only is now officinal, are all in a greater or less degree purgative, stomachic, and tonic; but, except in low states of the system, or in cases of individuals accustomed to the use of ardent spirits, they are too feebly cathartic in proportion to their stimulant power, to be advantageously employed, unless as adjuvants to other medicines. Combined with the neutral salts or other laxatives, or with tonic and stomachic infusions, mixtures, &c., they serve to render them warmer and more cordial to the stomach, and often prove beneficial in flatulent colic, dyspepsia, the costiveness of cold and irritable habits, diarrhœa, and other analogous complaints. One of them is to be preferred to another, according as its peculiar composition may, in the judgment of the practitioner, appear to adapt it to the circumstances of the case under treatment. In low forms of fever, when the indication is to evacuate the bowels, and at the same time stimulate the patient, the simple tincture (*Tinctura Rhei*) may be advantageously used in doses of two or three fluidrachms, repeated at proper intervals till it operates. The ordinary dose of these tinctures, as purgatives, is from half a fluidounce to a fluidounce; as stomachics, from one to two or three fluidrachms. According to Menière, the tincture of rhubarb yields on standing an abundant greenish precipitate, containing starch,* and consisting of two parts, one soluble and the other insoluble in alcohol, the latter having the form of long needles. (*Journ. de Pharm.*, Avril, 1861, p. 290.) From the statements of De la Rue and Muller it appears that much of the deposit in tincture of rhubarb consists of chrysophanic acid, suggesting the

* How starch should have found its way into the tincture it is difficult to understand. The observations of M. Menière were made with the microscope. He states that the deposits are made generally with extreme slowness. Whenever he noticed starch or gum, these substances were never deposited alone. In the midst of the deposits, he has often found a white pearly matter, uncrystallized, insoluble in water, which he believes to be hydrated silica, and certain salts, such as the sulphate and carbonate of lime, proceeding probably, as well as the silica, from the water used in diluting the alcohol. (*Journ. de Pharm.*, Avril, 1861, p. 288.)

propriety, at least in a pharmaceutical point of view, of increasing the alcoholic strength of the menstruum. W.

TINCTURA RHEI ET SENNÆ. *U. S.* *Tincture of Rhubarb and Senna.*

"Take of Rhubarb, in moderately coarse powder, *a troyounce;* Senna, in moderately coarse powder, Red Saunders, in moderately coarse powder, each, *one hundred and twenty grains;* Coriander, in moderately coarse powder, Fennel, in moderately coarse powder, Liquorice [extract], in moderately coarse powder, each, *thirty grains;* Raisins, deprived of their seeds, *six troyounces;* Diluted Alcohol *three pints.* Macerate for fourteen days, express, and filter through paper." *U. S.*

This is the stomachic so well known, and so much used in this country, under the name of *Warner's gout cordial.* It is a feeble purgative, usually acceptable to the stomach, and well adapted to cases of costiveness, with gastric uneasiness, in persons of a gouty habit, and accustomed to the free use of alcoholic drink. The dose is from half a fluidounce to two fluidounces. W.

TINCTURA SABINÆ. *Br.* *Tincture of Savin.*

The *British Pharmacopœia* directs this Tincture to be prepared from *two and a half avoirdupois ounces* of Savin, dried and bruised, and *one Imperial pint* of Proof Spirit, in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti,* page 1384.)

This is a new officinal of the British Pharmacopœia. It is a convenient form for the exhibition of savin. The dose is from twenty minims to a fluidrachm. W.

TINCTURA SANGUINARIÆ. *U. S.* *Tincture of Bloodroot.*

"Take of Bloodroot, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

This will prove emetic in the dose of three or four fluidrachms; but it is rather intended to act as a stimulant to the stomach, expectorant, or alterative, for which purpose from thirty to sixty drops may be given. W.

TINCTURA SCILLÆ. *U. S., Br.* *Tincture of Squill.*

"Take of Squill, in moderately coarse powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* directs this Tincture to be prepared from *two and a half avoirdupois ounces* of bruised Squill, and *one Imperial pint* of Proof Spirit, in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti,* page 1384.)

This tincture yields a grayish, rose-coloured, very bitter, and acrid deposit, consisting of silky tufts (*Menière*), possesses all the virtues of squill, and may be given for the same purposes, whenever the spirituous menstruum is not objectionable. The dose as an expectorant or diuretic is from ten to twenty minims (twenty to forty drops), and the latter quantity frequently nauseates. W.

TINCTURA SENEGÆ. *Br.* *Tincture of Seneka.*

The *British Pharmacopœia* prepares this Tincture from *two and a half avoirdupois ounces* of bruised Seneka, and *one Imperial pint* of Proof Spirit, in the same manner as directed for Tincture of Aconite Root. (See *Tinctura Aconiti,* page 1384.)

The tincture of senega has been newly introduced into the British Pharmacopœia. It is no doubt an efficient preparation, but hardly needed while recourse

can be had to the extract, syrup, and decoction. The dose is from thirty minims to two fluidrachms. W.

TINCTURA SENNÆ. *Br.* TINCTURA SENNÆ COMPOSITA. *Lond.* *Tincture of Senna. Compound Tincture of Senna.*

"Take of Senna, broken small, *two ounces and a half* [avoirdupois]; Raisins, freed from seeds, *two ounces* [avoird.]; Caraway, Coriander, each, *half an ounce* [avoird.]; Proof Spirit *one pint* [Imperial measure]." With these ingredients the British Pharmacopœia directs the tincture to be prepared in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This tincture is the *elixir salutis* of the old Pharmacopœias. It is a warm cordial purgative, useful in costiveness attended with flatulence, and in atonic gout, especially when occurring in intemperate persons. It is also added to cathartic infusions and mixtures. The dose is from two fluidrachms to a fluidounce or more. Tincture of senna gives a yellow deposit, disposed in plates, containing starch and white crystals of calcareous salts. (*Menière.*) W.

TINCTURA SERPENTARIÆ. *U. S., Br.* *Tincture of Serpentaria. Tincture of Virginia Snakeroot.*

"Take of Serpentaria, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Serpentaria, and *one Imperial pint* of Proof Spirit, and prepares the Tincture in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This tincture possesses the tonic and cordial properties of the root, and may be advantageously added to the infusion of Peruvian bark in low states of the system. The dose is one or two fluidrachms. W.

TINCTURA STRAMONII. *U. S., Br.* *Tincture of Stramonium.*

"Take of Stramonium Seed, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Stramonium Seeds, and *one Imperial pint* of Proof Spirit, and prepares the Tincture as directed for the Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This tincture may be used for all the purposes for which stramonium is given, in the dose of from ten to twenty minims (twenty to forty drops), repeated twice or thrice a day, and gradually increased till it affects the system. W.

TINCTURA TOLUTANA. *U. S., Br.* *Tincture of Tolu.*

"Take of Balsam of Tolu *three troyounces;* Alcohol *two pints.* Macerate the Balsam with the Alcohol until it is dissolved; then filter through paper." *U. S.*

"Take of Balsam of Tolu *two ounces and a half* [avoirdupois]; Rectified Spirit *one pint* [Imperial measure]. Macerate for six hours, or until the Balsam is dissolved, then filter, and add sufficient Rectified Spirit to make one pint [Imp. meas.]." *Br.*

The tincture of tolu has the properties of the balsam, and may be employed as an addition to expectorant mixtures in chronic catarrhal affections; but the proportion of alcohol is too large to allow of its advantageous use in ordinary cases. The dose is one or two fluidrachms. In smaller quantities it is often employed to flavour cough mixtures. It is decomposed by water.

Off. Prep. Syrupus Tolutanus, *U. S.*; Trochisci Acidi Tannici, *Br.*; Trochisci Morphiæ, *Br.*; Trochisci Morphiæ et Ipecacuanhæ, *Br.*; Trochisci Opii, *Br.* W.

TINCTURA VALERIANÆ. *U. S.*, *Br.* *Tincture of Valerian.*

"Take of Valerian, in moderately fine powder, *four troyounces;* Diluted Alcohol *a sufficient quantity.* Moisten the powder with a fluidounce of Diluted Alcohol, pack it in a conical percolator, and gradually pour Diluted Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* takes *two and a half avoirdupois ounces* of bruised Valerian, and *one Imperial pint* of Proof Spirit, and proceeds in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

This tincture possesses the properties of valerian, but cannot be given in ordinary cases, so as to produce the full effects of the root, without stimulating too highly, in consequence of the large proportion of spirit. The dose is from one to four fluidrachms. It deposits on standing a black, very cohesive precipitate, with starch, and a yellow extractive matter. (*Menière.*)

TINCTURA VALERIANÆ AMMONIATA. *U. S.*, *Br.* TINCTURA VALERIANÆ COMPOSITA. *Lond.* *Ammoniated Tincture of Valerian.*

"Take of Valerian, in moderately fine powder, *four troyounces:* Aromatic Spirit of Ammonia *two pints.* Macerate for seven days, express, and filter through paper." *U. S.*

"Take of Valerian, bruised, *two ounces and a half* [avoirdupois]; Aromatic Spirit of Ammonia *one pint* [Imperial measure]. Macerate the Valerian for seven days in a well-closed vessel, then filter, and add sufficient Aromatic Spirit of Ammonia to make one pint [Imp. meas.]." *Br.*

The ammonia in this preparation is thought to assist the solvent powers of the alcohol, while it co-operates with the valerian in medical action. The tincture is employed as an antispasmodic in hysteria and other nervous affections. The dose is from thirty minims to a fluidrachm, and should be given in sweetened water, milk, or some mucilaginous fluid. W.

TINCTURA VERATRI VIRIDIS. *U. S.* *Tincture of American Hellebore.*

"Take of American Hellebore, in moderately fine powder, *sixteen troyounces;* Alcohol *a sufficient quantity.* Moisten the powder with four fluidounces of Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

The U. S. tincture of American hellebore is of the same strength as Dr. Norwood's tincture, which, when prepared by its author, was supposed to be saturated. This may be true of certain ingredients of the root, though probably not in reference to the veratria, or to other active principle or principles which it may contain. The commencing dose should not exceed eight or ten drops. W.

TINCTURA ZINGIBERIS. *U. S*, *Br.* *Tincture of Ginger.*

"Take of Ginger, in fine powder, *eight troyounces;* Alcohol *a sufficient quantity.* Moisten the powder with two fluidounces of Alcohol, pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it until two pints of tincture are obtained." *U. S.*

The *British Pharmacopœia* prepares this Tincture from *two and a half avoirdupois ounces* of bruised Ginger, and *one Imperial pint* of Rectified Spirit, in the manner directed for Tincture of Aconite Root. (See *Tinctura Aconiti*, page 1384.)

The tincture of the British Pharmacopœia, though more than twice as strong as was that of the London and Edinburgh Colleges, is still too weak with ginger to be used advantageously for other purpose than to impart flavour. We greatly

prefer the U. S. process, which yields a preparation in which the virtues of the ginger are not completely swallowed up in the menstruum. In consequence of the mucilaginous matter contained in ginger, the tincture made with diluted alcohol or proof spirit is apt to be turbid. Alcohol or rectified spirit is, therefore, properly preferred. Good Jamaica ginger should be used.

The tincture of ginger is a useful carminative, and may often be beneficially added to tonic and purgative infusions or mixtures, in debilitated states of the alimentary canal. It is, however, in this country, chiefly used for the preparation of syrup of ginger, for which purpose it is necessary to employ the strong tincture of the U. S. Pharmacopœia.

Off. Prep. Syrupus Zingiberis. W.

TROCHISCI.

Troches.

Troches or *lozenges* are small, dry, solid masses, usually of a flattened shape, consisting for the most part of powders incorporated with sugar and mucilage. They are designed to be held in the mouth, and dissolved slowly in the saliva, and are, therefore, adapted for the administration of those medicines only which do not require to be given in large quantities, and are destitute of any very disagreeable flavour. They are much more used, and more skilfully prepared in Europe than in this country. Tragacanth, from the greater tenacity of its mucilage, is better suited for their formation than gum arabic. The following directions for preparing them are taken from the *Dictionnaire des Drogues*. A mucilage of tragacanth is first prepared with cold water and strained. With this the powders, including sugar, are thoroughly mixed by rubbing upon a marble slab, and are thus formed into a paste, which is spread out by means of a roller upon the surface of the marble, previously powdered over with a mixture of sugar and starch. The thickness of the extended mass is rendered uniform by a frame upon which the ends of the roller rest. The upper surface is now covered with a thin layer of sugar and starch, and the mass is divided into small cakes of a particular shape by means of a punch. These cakes are placed upon paper, and, having been exposed to the air for twelve hours, are carried into a drying room moderately heated. When perfectly dry, they are thrown upon a sieve to separate the sugar and starch, and are then enclosed in bottles. In this way lozenges may be prepared from almost any medicine which the physician may deem it advisable to administer in that form. The following formula will serve as a guide. Take of citric acid, in powder, a drachm; refined sugar eight ounces; oil of lemons twelve minims; mucilage of tragacanth a sufficient quantity. Form them in the manner above directed into troches of twelve grains each. A species of lozenge is made by uniting the aromatic essential oils with sugar alone; but their preparation belongs to the confectioner rather than to the apothecary.

The troches, formerly officinal, which are omitted in the present Pharmacopœias, are those of *Tartaric Acid*, *Gum Arabic*, *Lactucarium*, and *Liquorice*, all of the late Ed. Pharmacopœia. W.

TROCHISCI ACIDI TANNICI. *Br. Troches of Tannic Acid. Tannin Lozenges.*

"Take of Tannic Acid *three hundred and sixty grains;* Tincture of Tolu *half a fluidounce;* Refined Sugar, in powder, *twenty-five ounces* [avoirdupois]; Gum Arabic, in powder, *one ounce* [avoird.]; Mucilage of Gum Arabic *two fluidounces;* Boiling Distilled Water *one fluidounce.* Dissolve the Tannic Acid in the Water, add this solution to the Tincture of Tolu, previously mixed with the Mucilage; and with the Gum and the Sugar, also previously well

mixed, form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains half a grain of Tannic Acid." *Br.*

These are useful in relaxation of the uvula, and chronic inflammation of the fauces, being held in the mouth and allowed slowly to dissolve. W.

TROCHISCI BISMUTHI. *Br. Troches of Bismuth. Bismuth Lozenges.*

"Take of White Bismuth [Bismuthi Subnitras, *U.S.*] *fourteen hundred and forty grains;* Carbonate of Magnesia *four ounces* [avoirdupois]; Precipitated Carbonate of Lime *six ounces* [avoird.]; Refined Sugar *thirty ounces* [avoird.]; Gum Arabic, in powder, *one ounce* [avoird.]; Distilled Water *six fluidounces;* Oil of Cinnamon *half a fluidrachm.* Add the dry ingredients to the Water; mix thoroughly, and boil till the mixture is reduced to a proper consistence. Then remove it from the fire, add the Oil of Cinnamon, and again mix thoroughly. Divide the mass into 720 square lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains two grains of White Bismuth." *Br.*

These may be used to obtain the effects of subnitrate of bismuth on the system, two or more being administered for a dose. They may also be found useful in chronic inflammation of the throat and œsophagus, by giving the mucous membrane a coating as the insoluble ingredients pass. W.

TROCHISCI CATECHU. *Br. Troches of Catechu. Catechu Lozenges.*

"Take of Pale Catechu [Gambir], in powder, *two ounces* [avoirdupois]; Refined Sugar, in powder, *one pound* [avoird.]; Gum Arabic, in powder, *one ounce* [avoird.]; Tincture of Capsicum *half a fluidounce;* Distilled Water *a sufficiency.* Add to the Catechu, Sugar, and Gum Arabic, previously mixed, the Tincture of Capsicum, and sufficient Distilled Water to make a proper mass. Mix thoroughly, divide the mass into 720 lozenges, and dry these in a hot-air chamber with a moderate heat." *Br.*

These, like the troches of tannic acid, are useful in prolapsus of the uvula, and other forms of relaxation of the fauces; and may also be used, in the number of three or more at a dose, to obtain the effects of catechu on the primæ viæ and on the system. Each troche contains about 1·2 grains of catechu. W.

TROCHISCI CRETÆ. *U.S. Troches of Chalk.*

"Take of Prepared Chalk *four troyounces;* Gum Arabic, in fine powder, *a troyounce;* Nutmeg, in fine powder, *sixty grains;* Sugar, in fine powder, *six troyounces.* Rub them together until they are thoroughly mixed; then with water form a mass, to be divided into Troches, each weighing ten grains." *U. S.*

These are used as a gently astringent antacid in diarrhœa. W.

TROCHISCI CUBEBÆ. *U.S. Troches of Cubeb.*

"Take of Oleoresin of Cubeb *a fluidounce;* Oil of Sassafras *a fluidrachm;* Liquorice, in fine powder, Gum Arabic, in fine powder, Sugar, in fine powder, each, *three troyounces;* Syrup of Tolu *a sufficient quantity.* Rub the powders together until they are thoroughly mixed; then add the Oleoresin and Oil, and incorporate them with the mixture. Lastly, with Syrup of Tolu form a mass, to be divided into troches, each weighing ten grains." *U. S.*

Each lozenge contains about a drop of the oleoresin of cubeb. The preparation is intended rather for effect upon the fauces and other parts of the upper alimentary passages than on the system; and may be used advantageously in some cases of chronic cough, and in ulceration or chronic inflammation of the fauces, being held in the mouth and allowed slowly to dissolve. W.

TROCHISCI FERRI SUBCARBONATIS. *U.S. Troches of Subcarbonate of Iron.*

"Take of Subcarbonate of Iron *five troyounces;* Vanilla *sixty grains;* Sugar,

in fine powder, *fifteen troyounces;* Mucilage of Tragacanth *a sufficient quantity.* Rub the Vanilla first with a part of the Sugar into a uniform powder, and afterwards with the Subcarbonate of Iron and the remainder of the Sugar until they are thoroughly mixed. Then with Mucilage of Tragacanth form a mass, to be divided into troches, each weighing twenty grains." *U. S.*

Each lozenge contains somewhat less than five grains of the subcarbonate, and from one to six may be given, according to the effects desired. (See *Ferri Subcarbonatis.*) W.

TROCHISCI GLYCYRRHIZÆ ET OPII. *U. S.* Trochisci Opii. *Br. Troches of Liquorice and Opium. Opium Lozenges.*

"Take of Opium, in fine powder, *half a troyounce;* Liquorice, in fine powder, Gum Arabic, in fine powder, Sugar, in fine powder, each, *ten troyounces;* Oil of Anise *a fluidrachm.* Rub the powders together until they are thoroughly mixed; then add the Oil of Anise, and incorporate it with the mixture. Lastly, with water form a mass, to be divided into Troches, each weighing six grains." *U. S.*

"Take of Extract of Opium *seventy-two grains;* Tincture of Tolu *half a fluidounce;* Refined Sugar, in powder, *sixteen ounces* [avoirdupois]; Gum Arabic, in powder, *two ounces* [avoird.]; Extract of Liquorice *six ounces* [avoird.]; Boiling Distilled Water *a sufficiency.* Add the Extract of Opium, first softened by means of a little Water, and the Tincture of Tolu, to the Extract of Liquorice heated in a water-bath. When the mixture is reduced to a proper consistence remove it to a slab, add the Sugar and Gum, previously rubbed together, and mix thoroughly. Divide the mass into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains one-tenth of a grain of Extract of Opium." *Br.*

A preparation equivalent to the above is much used in Philadelphia under the name of *Wistar's cough lozenges.* Sometimes sulphate of morphia is substituted in equivalent proportion for the opium, and occasionally a little tartar emetic is added; but these modifications of the officinal formula are not admissible without a change of title. The British preparation is preferable on one account, that it uses, namely, the extract of opium instead of the crude drug.

These troches are demulcent and anodyne, and useful in allaying cough, when the case admits the employment of opium, of which each of them, prepared according to the U. S. formula, contains about one-tenth of a grain. W.

TROCHISCI IPECACUANHÆ. *U. S. Troches of Ipecacuanha.*

"Take of Ipecacuanha, in fine powder, *half a troyounce;* Arrow-root, in fine powder, *four troyounces;* Sugar, in fine powder, *fourteen troyounces;* Mucilage of Tragacanth *a sufficient quantity.* Rub the powders together until they are thoroughly mixed; then with Mucilage of Tragacanth form a mass, to be divided into Troches, each weighing ten grains." *U. S.*

These are useful expectorant lozenges in catarrhal complaints. Each of them contains about one-quarter of a grain of ipecacuanha. W.

TROCHISCI MAGNESIÆ. *U. S. Troches of Magnesia.*

"Take of Magnesia *four troyounces;* Nutmeg, in fine powder, *sixty grains;* Sugar, in fine powder, *twelve troyounces;* Mucilage of Tragacanth *a sufficient quantity.* Rub the Magnesia and the powders together until they are thoroughly mixed; then with Mucilage of Tragacanth form a mass, to be divided into Troches, each weighing ten grains." *U. S.*

These are useful in acidity of stomach, especially when attended with constipation. W.

TROCHISCI MENTHÆ PIPERITÆ. *U. S. Troches of Peppermint*

"Take of Oil of Peppermint *a fluidrachm;* Sugar, in fine powder, *twelve*

troyounces; Mucilage of Tragacanth *a sufficient quantity.* Rub the Oil of Peppermint with the Sugar until they are thoroughly mixed; then with Mucilage of Tragacanth form a mass, to be divided into Troches, each weighing ten grains." *U. S.*

Useful in slight gastric or intestinal pains, nausea, and flatulence; but employed more for their agreeable flavour than for their medicinal effects. W.

TROCHISCI MORPHIÆ. *Br. Troches of Morphia. Morphia Lozenges.*

"Take of Hydrochlorate of Morphia *twenty grains;* Tincture of Tolu *half a fluidounce;* Refined Sugar, in powder, *twenty-four ounces* [avoirdupois]; Gum Arabic, in powder, *one ounce* [avoird.]; Mucilage of Gum Arabic *two fluidounces*, or *a sufficiency;* Boiling Distilled Water *half a fluidounce.* Dissolve the Hydrochlorate in the Water; add this solution to the Tincture of Tolu, previously mixed with the Mucilage; and, with the Gum and the Sugar, also previously well mixed, form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat. Each lozenge contains one-thirty-sixth of a grain of Hydrochlorate of Morphia." *Br.*

Useful for alleviating cough, and for other purposes which are answered by minute doses of morphia, of the muriate of which each lozenge contains about one-thirty-sixth of a grain. W.

TROCHISCI MORPHIÆ ET IPECACUANHIÆ. *Br. Troches of Morphia and Ipecacuanha. Morphia and Ipecacuan Lozenges.*

"Take of Hydrochlorate of Morphia *twenty grains;* Ipecacuan, in fine powder, *sixty grains;* Tincture of Tolu *half a fluidounce;* Refined Sugar, in powder, *twenty-four ounces* [avoirdupois]; Gum Arabic, in powder, *one ounce* [avoird.]; Mucilage of Gum Arabic *two fluidounces*, or *a sufficiency;* Boiling Distilled Water *half a fluidounce.* Dissolve the Hydrochlorate of Morphia in the Water; add this solution to the Tincture of Tolu, previously mixed with the Mucilage; and, with the Ipecacuan, the Gum, and the Sugar, also previously well mixed, form a proper mass. Divide into 720 lozenges, and dry these in a hot-air chamber with a moderate heat." *Br.*

Expectorant and anodyne, useful especially in allaying cough. Each lozenge contains about one-thirty-sixth of a grain of muriate of morphia, and one-twelfth of a grain of ipecacuanha. W.

TROCHISCI SODÆ BICARBONATIS. *U. S. Troches of Bicarbonate of Soda*

"Take of Bicarbonate of Soda *four troyounces;* Sugar, in fine powder, *twelve troyounces;* Mucilage of Tragacanth *a sufficient quantity.* Rub the Bicarbonate of Soda with the Sugar until they are thoroughly mixed; then with Mucilage of Tragacanth form a mass, to be divided into Troches, each weighing ten grains." *U. S.*

Antacid and antilithic, useful in heartburn and uric acid gravel. W.

TROCHISCI ZINGIBERIS. *U. S. Troches of Ginger.*

"Take of Tincture of Ginger *a fluidounce;* Tragacanth, in fine power, *one hundred and twenty grains;* Sugar, in fine powder, *twelve troyounces;* Syrup of Ginger *a sufficient quantity.* Mix the Tincture of Ginger with the Sugar, and, having exposed the mixture to the air until dry, reduce it to fine powder; to this add the Tragacanth, and mix them thoroughly. Lastly, with Syrup of Ginger form a mass, to be divided into troches, each weighing twenty grains." *U. S.*

Each lozenge contains between one and two minims of the tincture, and they may be taken as required, being especially calculated to relieve gastric pains from flatulence. W.

UNGUENTA.

Ointments.

These are fatty substances, softer than cerates, of a consistence like that of butter, and such that they may be readily applied to the skin by inunction When ointments are prepared by merely mixing medicinal substances with simple ointment or *lard*, care should be taken, if the added substance be a powder that it be brought to the finest possible state of division, before being incorporated with the unctuous matter. If soluble in water or alcohol, it may often be advantageously rubbed with a little of one of these liquids. Gritty matter should not be allowed to enter these preparations. When an extract is added, if not uniformly soft, it should be made so by trituration with a little water or alcohol according to its nature. Many of the ointments become rancid if long kept, and should, therefore, be prepared in small quantities at a time, or only when wanted for use. The tendency to rancidity may be in a considerable degree counteracted by imbuing the unctuous vehicle with benzoin, or with poplar buds, as recommended by M. Deschamps (see *Am. Journ. of Pharm.*, xv. 260); but care should be taken that there be no therapeutical objection to the admixture.* Slippery elm bark is said to have the same effect. (See *page* 779.) According to Dr. Geisler, ten drops of spirit of nitric ether, incorporated with an ounce of ointment, obviates the disagreeable fatty odour of these preparations. (*Pharm. Cent. Blatt*, A.D. 1847, p. 927, from *Arch. der Pharm.*) It has been proposed to substitute glycerin for oils and fats in the preparation of ointments; but, when these are to be applied by inunction, it is altogether unfit for the purpose, as it remains upon the skin, producing a rough sensation of adhesiveness, very different from the softness caused by oleaginous matter under similar circumstances.

The Cerates having been abolished as a class in the British Pharmacopœia, a few of the individual articles have been transferred to the Ointments, making the definition of the latter class of preparations, as given above, not exactly applicable to all the individual substances at present included among them in that Pharmacopœia. We consider no substance as strictly entitled to the name of ointment, which is not of such a consistence as to adapt it to application to the skin by friction or inunction. The ointments formerly officinal, which have been omitted in the present U. S. and Br. Pharmacopœias, are *Adeps Suillus Praparatus*, Dub., *Unguentum Comii*, Lond., *Ung. Cupri Subacetatis*, U. S., Ed., Dub., *Ung. Hydrargyri Iodidi*, Lond., *Ung. Hydrarg. Nitratis Mitius*, Lond., *Ung. Opii*, Lond., *Ung. Picis*, Lond., *Ung. Plumbi Acetatis*, Ed., Dub., *Ung. Plumbi Iodidi*, Lond., Dub., and *Ung. Sulphuris Compositum*, U. S., Lond. W.

UNGUENTUM ACIDI TANNICI. *U. S. Ointment of Tannic Acid.*

"Take of Tannic Acid *thirty grains;* Water *half a fluidrachm;* Lard *a troyounce*. Rub the Acid first with the Water, and then with the Lard, until they are thoroughly mixed, avoiding the use of an iron spatula." *U. S.*

Ointment of tannic acid is an excellent application in many cases of piles and prolapsus ani, and has been highly recommended in inflammation of the vagina

* *Benzinated Lard* M. Emile Mouchon gives the following method of applying to lard the preservative influence of poplar buds and benzoin. Having prepared, by percolation, a *tincture of poplar buds* from one part of the dried buds in powder and four of alcohol, he adds by degrees to 1000 parts of melted lard 60 parts of the tincture, so that all the alcohol may be driven off, then strains, and agitates the mixture till it concretes on cooling. The same method is pursued with the tincture of benzoin, in the same proportions; and the tincture of guaiac will answer the same purpose. Lard thus prepared keeps perfectly well for a very long time. (*Journ. de Pharm.*, xxv. 458.)

Mr T B. Groves has shown that the oil of pimento and balsam of Peru have, in a powerful degree, the same preservative influence on lard. (*Pharm. Journ.*, Nov. 1864, p. 249.)

with purulold discharge, to which it is most conveniently applied spread thickly upon the surface of a tampon of linen. It may be used also in flabby ulcers. W.

UNGUENTUM ACONITIÆ. *Br. Ointment of Aconitia.*

"Take of Aconitia *eight grains;* Rectified Spirit *half a fluidrachm;* Prepared Lard *one ounce* [avoirdupois]. Dissolve the Aconitia in the Spirit, add the Lard, and mix thoroughly." *Br.*

For the uses of this preparation, the reader is referred to the articles on *Aconitum* and *Aconitia.* Care must be taken not to apply it to an abraded or ulcerated surface, lest it might produce serious constitutional effects. W.

UNGUENTUM ADIPIS. *U.S.* UNGUENTUM SIMPLEX. *Br., U.S.* 1850. *Ointment of Lard. Simple Ointment.*

"Take of Lard *eight troyounces;* White Wax *two troyounces.* Melt them together with a moderate heat, and stir the mixture constantly while cooling." *U. S.*

"Take of White Wax *two ounces* [avoirdupois]; Prepared Lard *three ounces* [avoird.]; Almond Oil *three fluidounces.* Melt the Wax and Lard in the Oil on a water-bath; then remove the mixture, and stir until it becomes solid." *Br.*

This is emollient, and is occasionally employed as a mild dressing to blistered or excoriated surfaces, but more frequently as a vehicle for more active substances. It is the basis of several officinal ointments.

Off. Prep. Ceratum Zinci Carbonatis, *U. S.;* Unguentum Antimonii Tartarati, *Br.;* Ung. Creasoti, *Br.;* Ung. Elemi, *Br.;* Ung. Gallæ, *Br.;* Ung. Hydrargyri Ammoniati; Ung. Hydrarg. Iodidi Rubri, *Br.;* Ung. Hydrarg. Oxidi Rubri; Ung. Plumbi Carbonatis; Ung. Resinæ, *Br.;* Ung. Zinci Oxidi, *Br.* W.

UNGUENTUM ANTIMONII. *U.S.* UNGUENTUM ANTIMONII TARTARATI. *Br. Ointment of Antimony. Antimonial Ointment. Tartar Emetic Ointment. Ointment of Tartarated Antimony.*

"Take of Tartrate of Antimony and Potassa, in very fine powder, *one hundred and twenty grains;* Lard *a troyounce.* Rub the powder with a little of the Lard, then add the remainder, and thoroughly mix them." *U.S.*

"Take of Tartarated Antimony, in fine powder, *a quarter of an ounce;* Simple Ointment *one ounce.* Mix thoroughly. This Ointment contains nearly twice as much Tartarated Antimony as Unguentum Antimonii Tartarizati, *Dub.*" *Br.*

This may be most conveniently prepared with *simple ointment,* as lard is too soft to be spread on linen, and simple ointment is sufficiently so to be applied by inunction.

The peculiar eruptive effects of tartar emetic may be procured by means of a strong solution, or of the powder sprinkled upon the surface or incorporated in the substance of some adhesive plaster, or of the ointment as above directed. The last method is, perhaps, the most convenient, and most generally resorted to. The proportion of tartar emetic may vary from one drachm with the ounce of lard to two drachms, as in the U. S. officinal formula, or even to three drachms when a speedy effect is required, or the skin is not very susceptible to its action. A small portion of the ointment may be rubbed twice a day, or more frequently, upon the surface to be affected, or it may be applied spread on a piece of linen. Care should be taken that the cuticle be entire, and that the application be not too long continued; as otherwise severe inflammation, and even gangrenous ulceration, may result. We have, however, in some instances of great urgency, applied the ointment to a surface recently scarified in the operation of cupping; but, under such circumstances, it should be used with much caution. W.

UNGUENTUM AQUÆ ROSÆ. *U.S. Ointment of Rose Water.*

"Take of Oil of Sweet Almonds *three troyounces and a half;* Spermaceti *a troyounce;* White Wax *one hundred and twenty grains;* Rose Water *two*

fluidounces. Melt together, by means of a water-bath, the Oil, Spermaceti, and Wax; then add gradually the Rose Water, and stir the mixture constantly while cooling." *U. S.*

This preparation is much employed under the name of *cold cream.* It is a white, very soft, and elegant unguent, deriving a grateful odour from the rose water, which remains incorporated with the other constituents if kept enclosed in glazed vessels. It is a pleasant, cooling application to irritated and excoriated surfaces; and may be used with great advantage for chapped lips and hands, so frequent in cold weather. As the ointment is liable to become rancid when long kept, and the water to separate upon exposure, Mr. Joseph Laidley has proposed the substitution for the rose water of oil of roses and glycerin, the former in the proportion of two drops, the latter in that of four fluidrachms, the quantity of spermaceti being increased by two drachms. (*Am. Journ. of Pharm.*, xii. 119.) For some purposes the substitution is useful; but the officinal preparation is preferable for chapped hands, as the glycerin, not being absorbed, leaves an unpleasant sensation of stickiness on the skin. W.

UNGUENTUM ATROPIÆ. *Br. Ointment of Atropia.*

"Take of Atropia *eight grains;* Rectified Spirit *half a fluidrachm;* Prepared Lard *one ounce* [avoirdupois]. Dissolve the Atropia in the Spirit, add the Lard, and mix thoroughly." *Br.*

For the uses of this ointment, see *Belladonna* and *Atropia.* Great caution must be observed that the ointment shall not come in contact with abraded, ulcerated, or wounded surfaces; and that the cuticle of the part to which it may be applied shall be entire. W.

UNGUENTUM BELLADONNÆ. *U. S., Br. Ointment of Belladonna.*

"Take of Extract of Belladonna *sixty grains;* Water *half a fluidrachm;* Lard *a troyounce.* Rub the Extract first with the Water, until rendered uniformly soft, then with the Lard, and thoroughly mix them." *U. S.*

"Take of Extract of Belladonna *eighty grains;* Prepared Lard *one ounce* [avoirdupois]. Rub the Extract smooth with a few drops of distilled water, then add the Lard, and mix thoroughly." *Br.*

This is a convenient form for the external application of the extract of belladonna. Care must be taken in preparing it that the extract employed have the due consistence; and, if dry and lumpy, it may be restored to the proper state by rubbing it with a little water in a heated mortar. W.

UNGUENTUM BENZOINI. *U. S. Ointment of Benzoin.*

"Take of Benzoin, in moderately coarse powder, *a troyounce;* Lard *sixteen troyounces.* Heat them together, by means of a water bath, for two hours, with occasional stirring; then strain without pressure, and stir the product constantly while cooling." *U. S.*

Benzoin has the property of obviating the rancidity to which lard and other unctuous substances are liable. Hence, the ointment under consideration is peculiarly useful as the vehicle of medicines used in this form; and may often be substituted for pure lard in the preparation of other unguents, of which lard is an ingredient, when it is desired to preserve them from change. It is recommended, moreover, by its agreeable odour; while there are very few ointments or cerates with the uses of which it would interfere. Balsam of Peru, rubbed with an ointment in the proportion of five drops to a fluidounce, will have the same effect. W.

UNGUENTUM CALOMELANOS. *Br. Ointment of Calomel.*

"Take of Calomel *eighty grains;* Prepared Lard *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

There is little occasion for such a preparation as this. Calomel is much infe-

rior for affecting the system by inunction to the mercurial ointment; and as an application to ulcerated surfaces the form of cerate would be better. It may, however, be useful in certain cutaneous eruptions by being rubbed upon the part. W.

UNGUENTUM CANTHARIDIS. *Br.* *Ointment of Cantharides. Ointment of Spanish Flies.*

"Take of Cantharides, Yellow Wax, each, *one ounce* [avoirdupois]; Olive Oil *six fluidounces.* Digest the Cantharides in the Oil, in a covered vessel, for twelve hours, then place the vessel in a water-bath at 212° for fifteen minutes, strain through muslin with strong pressure, add the product to the Wax previously melted, and stir constantly until the mixture solidifies." *Br.*

In the former officinal processes the virtues of the flies were extracted by boiling them with water; but olive oil is a good solvent of their active principle, and has been very properly substituted in the present British formula.

By this process, the active matter of the flies is more uniformly diffused through the ointment than when they are directly incorporated, in the state of powder, with the other ingredients. The preparation is thus better calculated to meet the end proposed of maintaining the discharge from blistered surfaces, without producing undue irritation. It has been said that the virtues of the flies are impaired by boiling; but the contrary has been proved to be the case; the cantharidin being neither altered nor volatilized at 212°. (See *Cantharis.*) It should be recollected that this ointment is intended as a dressing for blisters, not to produce vesication. We regret its omission in the present U. S. Pharmacopœia, as there is no preparation capable of answering the purpose for which it was intended so well on the whole as this. *Dupuytren's ointment*, employed as a local application to prevent the loss of hair, was made by macerating a drachm of flies in a fluidounce of alcohol, and incorporating one part of the tincture thus formed with nine parts of lard. W.

UNGUENTUM CETACEI. *Br.* *Spermaceti Ointment.*

"Take of Spermaceti *five ounces* [avoirdupois]; White Wax *two ounces* [avoird.]; Almond Oil *one pint* [Imperial measure], or *a sufficiency.* Melt together with a gentle heat, remove the mixture, and stir constantly until it solidifies." *Br.*

This ointment is employed as a mild dressing for blisters, wounds, and excoriated surfaces. It should be made in small quantities at a time, as it is apt to become rancid when long kept. W.

UNGUENTUM COCCULI. *Br.* *Ointment of Cocculus.*

"Take of the Seeds of Cocculus Indicus *eighty grains;* Prepared Lard *one ounce* [avoirdupois]. Beat the Seeds well in a mortar, and rub them with the Prepared Lard." *Br.*

This ointment is used for the destruction of vermin, and in the cure of scabies and ringworm of the scalp. In the latter complaint it was found very useful by the late Dr. Hamilton, sen., of Edinburgh. W.

UNGUENTUM CREASOTI. *U. S., Br.* *Ointment of Creasote.*

"Take of Creasote *half a fluidrachm;* Lard *a troyounce.* Mix them." *U. S.*

"Take of Creasote *one fluidrachm;* Simple Ointment *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

The British ointment is more than twice as strong as ours; but this is hardly a recommendation.

For the use of this ointment, see *Creasotum.* It may sometimes be advantageously diluted with lard when found to irritate. W.

UNGUENTUM ELEMI. *Br.* *Ointment of Elemi.*

"Take of Elemi *a quarter of an ounce;* Simple Ointment *one ounce.* Melt, strain through flannel, and stir constantly until the Ointment solidifies." *Br.*

This ointment is applied as a gentle stimulant to weak ulcers, and may be used for maintaining the discharge of issues and setons. It is the *linimentum arcæi* of the older pharmacy. W.

UNGUENTUM GALLÆ. *U. S., Br. Ointment of Nutgall. Ointment of Galls.*

"Take of Nutgall, in very fine powder, *a troyounce;* Lard *seven troyounces.* Mix them." *U. S.*

"Take of Galls, in very fine powder, *eighty grains;* Simple Ointment *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

This is used chiefly in piles and prolapsus ani, though it may also be advantageously applied to flabby and indolent ulcers. W.

UNGUENTUM GALLÆ CUM OPIO. *Br. Ointment of Galls and Opium.*

"Take of Ointment of Galls *one ounce* [avoirdupois]; Opium, in powder, *thirty-two grains.* Mix thoroughly" *Br.*

This combination of galls and opium is sometimes employed, preferably to the simple ointment of galls, in cases of irritable piles. From half a drachm to a drachm of camphor is sometimes added to the London ointment. W.

UNGUENTUM HYDRARGYRI. *U. S., Br. Mercurial Ointment.*

"Take of Mercury *twenty four troyounces;* Lard, Suet, each, *twelve troyounces.* Rub the Mercury with a troyounce of the Suet and a small portion of the Lard until the globules cease to be visible; then add the remainder of the Lard and of the Suet softened with a gentle heat, and thoroughly mix them." *U. S.*

"Take of Mercury, Prepared Lard, each, *one pound* [avoirdupois]; Prepared Suet *one ounce* [avoird.]. Rub them together until metallic globules cease to be visible." *Br.*

The Pharmacopœias unite at present in recognising but one mercurial ointment, which contains equal weights of mercury and fatty matter. When the physician wishes a weaker preparation, he may direct the ointment to be diluted with such a proportion of lard as may answer his purposes.

In the preparation of mercurial ointment, care is requisite that the mercury should be completely extinguished. The trituration is best performed in a marble mortar; as it is difficult to keep iron so clean as not to impart more or less oxide to the ointment. The mercury is known to be extinguished, when a portion of the mass, rubbed upon paper or the back of the hand, exhibits no metallic globules under a magnifying glass of four powers. The operation cannot be considered as satisfactorily accomplished when the globules are invisible merely to the naked eye. To facilitate the process, which is very tedious, the addition of various substances has been proposed, calculated to hasten the disappearance of the metal. Turpentine and sulphur have been employed, but are inadmissible; the former because it renders the ointment too irritating, the latter because it forms with the mercury an inactive sulphuret. Their presence in the ointment may be detected by the peculiar odour which they respectively emit when exposed to heat. Sulphur, moreover, gives the ointment a darker colour than it has when pure. The addition of a little sulphuric ether, at intervals, during the trituration, is said greatly to abbreviate the process. (*Am. Journ. of Pharm.*, xvii. 80.) Rancidity in the lard employed facilitates the extinguishment of the mercury, but is liable to the same objection as turpentine, though in a much less degree. M. Fossembras found that the addition of rancid fat was required in the proportion of only ten drachms to a pound of the ointment, in order to enable eight pounds to be prepared in an hour. (*Journ. de Pharm., 3e sér.*, v. 75.) M. Guibourt recommends the addition of one-sixteenth of old mercurial

ointment.* M. Simonin proposes the use of lard which has been exposed in thin layers to a damp air for fifteen days. This facilitates the extinguishment of the metal, but it probably renders the preparation more irritant by the chemical alteration of the lard. The following plan of preparing the ointment was proposed by M. Chevallier. A pound of mercury, and half a pound of fresh lard previously melted, are introduced into a stone or glass bottle, shaken till the mixture acquires the consistency of very thick syrup, then poured into a mortar, and incorporated by constant stirring with an additional half pound of lard. In this manner, according to Chevallier, a perfect ointment may be made in half an hour. When prepared with lard alone, the ointment is apt, in hot weather, to become so soft as to allow the metal to separate. Hence the addition of suet in the processes of the U. S. and British Pharmacopœias; and even a larger proportion might be employed, when the ointment is prepared for use in the summer season.

Upon the whole, it may be considered doubtful whether any of the expedients for saving labour and time in the preparation of the ointment are wholly unobjectionable. Dr. Christison states that the better plan is not to complete the process by a continuous trituration, but to operate for a short time every day, and allow the ointment in the mean time to be exposed to the air. But so much labour is required in the process, that the ointment is preferably made by machinery on the large scale. The fatty matters, kept in the fluid state by a heat of about 100°, are triturated with the metal by means of two iron balls, which are driven rapidly round in a circular iron trough by steam power. The extinguishment of the mercury is thus effected in about twelve hours.

A new method of preparing mercurial ointment, proposed by Orosi, is to precipitate metallic mercury, in the pulverulent form, from a solution of corrosive sublimate, by an excess of protochloride of tin, with the addition of muriatic acid; and, having poured off the supernatant fluid, washed the precipitate with warm water, and dried it between bibulous paper, to incorporate it with the prescribed proportion of lard. To prevent the precipitated mercury from running into globules, it is recommended to cover with fat the interior of the vessel in which the precipitation takes place.

Mercurial ointment has when newly prepared a bluish colour, which becomes darker by age. It has been thought to contain the mercury in the state of protoxide; but most of the metal can be separated by methods not calculated to reduce the oxide; and it is now generally admitted that by far the greater part of it exists in a state of minute division, not of chemical combination. It has been shown, however, that the metal is slightly oxidized; and the change of colour which the ointment undergoes with age is attributable to further oxidation. If the ointment be kept long melted in a narrow vessel, metallic mercury subsides, and an oily liquid floats upon the surface. After this has been filtered so as to separate everything undissolved, it is blackened by sulphuretted hydrogen, and yields oxide of mercury to acetic acid. Dr. Christison states that he has examined various samples of the ointment, and never failed to detect oxide of mercury; and he has inferred from his observations that the oxide amounts

* It appears that Mr. J. Higginbottom made known, so long ago as the year 1814, this mode of extinguishing mercury. He recommends that equal weights of the old ointment and of mercury should be rubbed together, till the globules quite disappear, and the requisite proportion of lard then added. It is not necessary that the mercurial ointment should be rancid. (*Pharm. Journ.*, xvi. 215.) For a process recommended by Mr. J. M. Maisch, of which the peculiarity is the use of mercury passed through chamois leather, so as to be sprinkled in minute division over the fat, see the *Am. Journ. of Pharm.* (xxviii. 107); and for another by Mr. E. H. Hance, in which melted spermaceti is employed as the extinguishing material, and which is said to answer well for small quantities, see the same journal (xxix. 15). M. E. Mouchon uses wax or stearin to facilitate extinguishment, and recommends benzinated lard as the vehicle. (*Journ. de Chim. Méd.*, Nov. 1856, p. 652.)—*Note to the eleventh edition.*

to rather more than 1 per cent. (*Christison's Dispensatory.*) But the proportion is variable, according to the age and mode of preparation of the ointment It scarcely admits of a doubt, that the oxide of mercury formed enters into chemical combination with the lard, or one of its oily acids. Mr. Donovan advanced the idea, that the medicinal activity of the ointment depended exclusively on this compound of the lard with the mercurial oxide. An ointment made by merely mixing lard and black oxide of mercury has not the same effect; because there is no chemical union between the ingredients. But, upon exposing such a mixture to a temperature of 350°, and continually agitating it for two hours, he found that every ounce of lard dissolved and combined with twenty-one grains of oxide, and the resulting compound was proved to be equally effectual with the common ointment, and capable of being introduced into the system in one-third of the time. It has been proposed to substitute an ointment thus prepared for that made according to the officinal directions, as being more manageable, and of more uniform strength. Care, however, would be required in preparing it to avoid a temperature either too high or too low; as the former might decompose the oxide, and the latter would be insufficient to effect its union with the lard. There would be danger, also, that the lard might be rendered irritant by the influence of the heat. Dr. F. Von Bærensprung has rendered it extremely probable that metallic mercury, no matter in what state of division it may be, is unable to enter the blood-vessels, and that whatever effects on the system are produced by the ointment, or any similar preparation, or even by the vapours of mercury, are owing to the previous oxidation of the metal. (See *Chem. Gaz.*, Sept. 1, 1850, p. 321.)

From experiments by a committee of the College of Pharmacy, of New York, it appears that the ointment, contained in jars, becomes somewhat unequal in consequence of the settling of the metallic ingredient. The inference is that, after long standing, the contents of the jar should be triturated so as to restore an equable strength before being dispensed. (*Am. Journ. of Pharm.*, xvi. 2.)

Medical Uses. Mercurial ointment, when rubbed upon the surface of the body, produces, in consequence of its absorption, the general effects of mercury upon the system. It is resorted to either alone, when circumstances prevent or discourage the internal use of mercury, or conjointly with the internal use of the medicine, to produce a more speedy or powerful effect in urgent cases. It may also be advantageously employed as a resolvent in local affections; as in the case of venereal buboes, and of chronic glandular swellings, upon which it may be made to operate directly by being applied in the course of the absorbents passing through the enlarged glands. The proper quantity to be employed at one time, with a view to salivation, is about a drachm, which should be applied night and morning, by means of friction, to the inner surface of the thighs, legs, or arms, and continued till the system is affected.

In urgent cases, or in local affections, it may also be rubbed on other parts of the body, or applied to blistered surfaces. The friction should on each occasion be continued till the whole of the ointment is absorbed. When frequently rubbed upon the same part, it is apt to produce a disagreeable eruption, which interferes with its continued application. Camphor is sometimes added, in order to render it more easy of absorption; but, without producing this effect, it increases the liability of the ointment to irritate the skin, and is of no other advantage than to soften its consistence when too firm from a large proportion of suet. Mercurial ointment has been employed, with some success, to prevent the maturation of the smallpox pustule, and the consequent pitting. For this purpose it may be applied to the face or other part, thickly spread on patent lint or muslin, care being taken to prevent the access of the air to the covered part. To be successful it must be applied before the third or fourth day of the eruption. The ointment has been recommended also in erysipelas and chilblains.

Iodide of potassium, rubbed with mercurial ointment, is said to promote the separation of the mercury in the form of globules (*Journ. de Pharm.*, 3*e sér.*, x. 356); but the effect does not take place if the iodide is thoroughly dried and well powdered, and the ointment added to it by small portions at a time. (*Ibid.*, x. 421.) The ointment, diluted with twice or three times its weight of lard, is sometimes applied to ulcers, and to certain cutaneous eruptions.

Off. Prep. Linimentum Hydrargyri, *Br.* W.

UNGUENTUM HYDRARGYRI AMMONIATI. *U. S.*, *Br.* Unguentum Præcipitati Albi. *Br.* *Ointment of Ammoniated Mercury. Ointment of White Precipitate.*

"Take of Ammoniated Mercury, in very fine powder, *forty grains;* Ointment of Lard *a troyounce.* Mix them." *U. S.*

"Take of Ammoniated Mercury *sixty-four grains;* Simple Ointment *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

This ointment is employed chiefly in cutaneous eruptions, such as psora, porrigo, and herpes. W.

UNGUENTUM HYDRARGYRI IODIDI RUBRI. *Br.* *Ointment of Red Iodide of Mercury.*

"Take of Red Iodide of Mercury, in very fine powder, *sixteen grains;* Simple Ointment *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

This ointment contains only one-fourth as much of the red iodide as the ointment of the Dublin College, which it supersedes. It is employed as a dressing to scrofulous ulcers, especially when they are very indolent. W.

UNGUENTUM HYDRARGYRI NITRATIS. *U. S.*, *Br.* Unguentum Citrinum. *Ed.* *Ointment of Nitrate of Mercury. Citrine Ointment.*

"Take of Mercury *a troyounce and a half;* Nitric Acid *three troyounces and a half;* Neats-foot Oil *twelve troyounces;* Lard *four troyounces and a half.* Dissolve the Mercury in the Acid; then heat together the Oil and Lard in an earthen vessel, and, when the temperature reaches 200°, remove the mixture from the fire. To this add the mercurial solution, and with a wooden spatula stir constantly, so long as effervescence continues, and afterwards occasionally until the ointment stiffens." *U. S.*

"Take of Mercury *four ounces* [avoirdupois]; Nitric Acid *eight fluidounces;* Prepared Lard *fifteen ounces* [avoird.]; Olive Oil *thirty-two fluidounces.* Dissolve the Mercury in the Nitric Acid with the aid of a gentle heat; melt the Lard in the Oil, by a steam or water bath, in a porcelain vessel capable of holding six times the quantity; and, while the mixture is hot, add the Solution of Mercury, also hot, mixing them thoroughly. If the mixture do not froth up, increase the heat till this occurs." *Br.*

The chemical changes which take place in the preparation of this ointment are not precisely known. They differ somewhat according to the circumstances under which the operation is performed; for example, according to the proportion and strength of the acid, the nature of the fatty matter, and the degree of heat employed. The mercury, in the first step of the process, is oxidized at the expense of a portion of the acid, nitrous fumes escape, and the undecomposed acid unites with the oxidized metal, forming binitrate of deutoxide of mercury if heat be employed, and a mixture of this with nitrate of the protoxide, if the process be conducted at a low temperature. When the mercurial solution is added to the fatty matter, a reaction takes place, which probably results in the production of the yellow subnitrate of the deutoxide of mercury, of one or more of the fatty acids, as the oleic, margaric, and stearic, and of elaïdin or elaïdic acid, or both. (See *page* 568.) It is also highly probable that portions of these fatty acids combine with the oxide of mercury. But the degree to which these

changes take place is influenced greatly by the temperature to which the mixture is exposed. If this be low, there is little or no escape of gas; if elevated, there is a copious evolution of nitrous fumes. In the former case the changes are obviously less considerable than in the latter.

As formerly prepared, this ointment, though at first beautifully yellow and of the proper consistence, soon began to change, acquiring in time a dirty greenish and mottled colour, and becoming so hard and friable as to be unfit for use unless mixed with lard. These results were ascribed to various causes, and as many different modifications of the process were proposed in order to obviate them. The U. S. process is based upon the fact, that the olive oil of the former British processes is hardened by nitrous acid or the nitrate of mercury, while the same effect is not produced upon neats-foot oil. As at first published, the process was defective in the direction to add the mercurial solution to the mixed oleaginous fluid when it begins to stiffen on cooling. When this direction was complied with, at least with the acid of the ordinary strength, the preparation had a brown colour and semi-liquid consistence; but, with some modifications such as were introduced into the revised formula of the Pharmacopœia of 1850, the process yields an excellent ointment, which, though it sometimes assumes a greenish colour on exposure, retains permanently a soft unctuous consistence. We have had specimens of the ointment in our possession for several years, which have retained a uniform yellowish colour, and a perfectly good unctuous consistence. It is said that the three ounces of lard of this formula may be advantageously replaced by the same quantity of neats-foot oil. (*Am. Journ. of Pharm.*, iv. 197.) It is probable that other animal oils will answer the same purpose; and it is asserted that a good preparation may be made with lard or butter alone. The drying vegetable oils do not appear, like olive oil, to be converted by nitrous acid or the nitrate of mercury into elaïdin; and it was a fair inference that they might be employed advantageously in the preparation of citrine ointment. Accordingly, Dr. Fessenden, of North Carolina, states, in his inaugural essay, that he substituted linseed oil for the neats-foot oil of the U. S. process, and succeeded in obtaining a perfectly good and durable ointment. It is now stated that the failure of many operators who have followed the former British officinal processes, has been owing not so much to the character of the particular oil employed, as to deficiency of strength in the nitric acid, and the want of a due degree of heat. Mr. Alsop asserts that, if the nitric acid be of the sp. gr. 1 5, or if the quantity of a weaker acid be increased so as to compensate for its deficiency in strength, and if the fatty matters be mixed with the mercurial solution at an elevated temperature, a permanently soft and golden-coloured ointment will result. (*Pharm. Transact.*, Sept. 1841.) It is probable that the discoloration which is so apt to take place in the preparation is owing to the deoxidizing influence of the fatty matter upon the mercurial oxide. Now if, by a sufficient excess of acid and an elevated temperature, the fats be well oxidized during the process, they will have less affinity for oxygen afterwards, and consequently less ability to take it from the oxide of mercury. That they are oxidized at the expense of the nitric acid, when heat is used, is proved by the abundant extrication of nitrous fumes during the operation.

But, when the fatty matter and mercurial solution are mixed, care must be taken that the heat applied be not too great. Gas is extricated at 180°, and at 212° escapes so abundantly that the mixture boils over unless the vessel is very large. (*Alsop.*) Besides, if the heat is too great, a portion of the mercury is reduced, and the colour of the ointment impaired. When large quantities of materials are operated upon, the reaction which occurs produces of itself a sufficient heat; but in ordinary cases the temperature should be kept at about 190° by means of a water-bath, and if it exceed 205° should be reduced. It should always be sufficient to produce a copious extrication of gas. The ointment should be pre-

pared in a glass, porcelain, or well-glazed earthen vessel; and a glass rod or wooden spatula should be employed for stirring the mixture.

In the present U. S. and British formulas, the provision in relation to the application of heat is incorporated; and either of them will yield a good ointment with due care in the manipulations. For some useful practical hints upon this point, the reader is referred to a communication by Mr. Joseph Laidlaw in the *Am. Journ. of Pharm.* (xxii. 119). It is due to Mr. Duncan, a chemist and druggist of Edinburgh, to state that he appears to have been the first to ascertain the value of heat in the preparation of this ointment.

Medical Uses. This ointment is much and very advantageously employed, as a stimulant and alterative application, in porrigo or tinea capitis, impetigo larvalis or crusta lactea, psoriasis and pityriasis, certain forms of chronic eczema, psorophthalmia and inflammation of the eye and eyelids connected with porrigo of the face or scalp, and various other ulcerative and eruptive affections. It should be diluted with lard, unless in cases which require a very stimulant application. Some care is requisite in its use, to avoid the risk of salivation. When hard and friable, it must be rubbed up with fresh lard before it can be applied.

An ointment prepared with lard and nitric acid, called *Alyon's ointment*, after the person who first prepared it, was formerly much used in cases similar to those in which the citrine ointment is now employed. The *ointment of nitric acid* of the former Edinburgh and Dublin Pharmacopœias, discarded in the last edition of those works, was of this character. W.

UNGUENTUM HYDRARGYRI OXIDI RUBRI. *U. S.*, *Br. Ointment of Red Oxide of Mercury.*

"Take of Red Oxide of Mercury, in very fine powder, *sixty grains:* Ointment of Lard *a troyounce.* Add the Oxide of Mercury to the Ointment previously softened with a gentle heat, and thoroughly mix them." *U. S.*

"Take of Red Oxide of Mercury, in very fine powder, *sixty four grains;* Simple Ointment *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

The red oxide of mercury here referred to is that prepared from the nitrate, and usually called *red precipitate.* It is important that the oxide should be thoroughly pulverized before being mixed with the lard; as otherwise it might prove injurious in cases of ophthalmia, in which it is sometimes used.

This ointment loses its fine red colour when long kept, probably in consequence of the conversion of the red oxide into the black, or its reduction to the metallic state. It is best to prepare it only in small quantities at a time. We have been informed that, if the preparation be made by mixing the red oxide with poplar-bud ointment, it will keep a long time without change. According to R. H. Stabler, of Alexandria, Va., an equally effectual method is to mix two drops of Liquor Potassæ with each ounce of the ointment when prepared. (*Am. Journ. of Pharm.*, xxiii. 123.) It is a highly useful stimulating ointment, much employed in indolent and foul ulcers, in porrigo of the scalp, psorophthalmia, and chronic conjunctival ophthalmia, especially when attended with thickening of the inner membrane of the eyelids, or with specks upon the cornea. It may be diluted with lard if found too stimulating. W.

UNGUENTUM IODINII. *U. S. Ointment of Iodine.*

"Take of Iodine *twenty grains;* Iodide of Potassium *four grains:* Water *six minims;* Lard *a troyounce.* Rub the Iodine and Iodide of Potassium first with the Water, and then with the Lard until they are thoroughly mixed." *U. S.*

The object of the iodide of potassium and water is simply to bring the iodine into a state in which it may be thoroughly and equably incorporated with the lard. They have been found to answer better in practice than the alcohol formerly used.

This ointment, when rubbed upon the skin, imparts to it an orange colour,

which, however, slowly disappears with the evaporation of the iodine. It is useful as a local application in goitre, scrofulous swellings of the glands and other chronic tumefactions, internal or external, operating probably through the medium of absorption. When continued for some time it occasionally produces a pustular eruption upon the portion of skin to which it is applied. Dr. Cerchi ari strongly recommends it in cases of enlarged tonsils, after the disappearance of inflammation. It should be applied to the tonsils morning and evening by means of a camel's hair pencil. In two months, according to the author, the enlargement disappears. (*Am. Journ. of Pharm.*, viii. 83.) It has also been recommended in chilblains. The ointment should be prepared only when wanted for use; for it undergoes change if kept, losing its deep orange-brown colour, and becoming pale upon the surface. W.

UNGUENTUM IODINII COMPOSITUM. *U. S.* Unguentum Iodi Compositum. *Br.* *Compound Ointment of Iodine.*

"Take of Iodine *fifteen grains;* Iodide of Potassium *thirty grains;* Water *thirty minims;* Lard *a troyounce.* Rub the Iodine and Iodide of Potassium first with the Water, and then with the Lard until they are thoroughly mixed." *U. S.*

"Take of Iodine, Iodide of Potassium, each, *thirty-two grains;* Proof Spirit *one fluidrachm;* Prepared Lard *two ounces* [avoirdupois]. Rub the Iodine and the Iodide of Potassium well together, with the Spirit, in a glass or porcelain mortar, add the Lard gradually, and mix thoroughly." *Br.*

This preparation is employed for the same purposes as the preceding, from which it differs chiefly in being somewhat stronger with iodine; as the iodide of potassium is probably not peculiar in its effects, and the spirit is employed only to facilitate the admixture. W.

UNGUENTUM MEZEREI. *U. S.* 1850. *Ointment of Mezereon.*

"Take of Mezereon, sliced transversely, *four* [*troy*]*ounces;* Lard *fourteen* [*troy*]*ounces;* White Wax *two* [*troy*]*ounces.* Moisten the Mezereon with a little Alcohol, and beat it in an iron mortar until reduced to a fibrous mass; then digest it, by means of a salt-water bath, with the Lard and Wax previously melted together, for twelve hours; strain with strong expression, and allow the strained liquid to cool slowly, so that any undissolved matters may subside. From these separate the medicated ointment." *U. S.*

Though discarded from the Pharmacopœia at the recent revision of that work, we retain the formula, because the ointment is, in our estimation, valuable for the purposes for which it was intended. It is equivalent to the *pommade épispastique au garou* of the French Codex, which is prepared from the bark of *Daphne Gnidium.* The ointment may also be made, as proposed by Guibourt, by mixing two drachms of the alcoholic extract of mezereon with nine ounces of lard and one of wax. It is used as a stimulating application to blistered surfaces in order to maintain the discharge, and to obstinate, ill-conditioned, and indolent ulcers. W.

UNGUENTUM PICIS LIQUIDÆ. *U. S.* *Tar Ointment.*

"Take of Tar, Suet, each, *twelve troyounces.* Mix the Tar with the Suet previously melted with a moderate heat, and, having strained the mixture through muslin, stir it constantly while cooling." *U. S.*

This ointment is highly useful as a stimulant application in various scaly and scabby eruptions, particularly in psoriasis and lepra, and in that form of porrigo usually called tinea capitis, or scald-head. In the last-mentioned affection, it should be applied night and morning; and in bad cases the patient should constantly wear a cap, thickly coated internally with the ointment. W.

UNGUENTUM PLUMBI CARBONATIS. *U. S.*, *Br.* *Ointment of Carbonate of Lead.*

"Take of Carbonate of Lead, in very fine powder, *eighty grains;* Ointment of Lard *a troyounce.* Add the Carbonate of Lead to the Ointment previously softened with a gentle heat, and thoroughly mix them." *U. S.*

"Take of Carbonate of Lead, in fine powder, *sixty-four grains;* Simple Ointment *one ounce* [avoirdupois]. Mix thoroughly." *Br.*

This ointment is used as a dressing to blistered or excoriated surfaces, burns, &c. W.

UNGUENTUM PLUMBI SUBACETATIS. *Br.* *Ointment of Subacetate of Lead.*

See CERATUM PLUMBI SUBACETATIS.

UNGUENTUM POTASSII IODIDI. *U. S.*, *Br.* *Ointment of Iodide of Potassium.*

"Take of Iodide of Potassium, in fine powder, *sixty grains;* Water *a fluidrachm;* Lard *a troyounce.* Dissolve the Iodide of Potassium in the Water, and mix the solution with the Lard." *U. S.*

"Take of Iodide of Potassium *sixty-four grains;* Distilled Water *one fluidrachm;* Prepared Lard *one ounce* [avoirdupois]. Dissolve the Iodide of Potassium in the Water, and mix thoroughly with the Lard." *Br.*

The preparation is apt to become discoloured by time in consequence of the liberation of iodine. It is said that this may be prevented by mixing two drops of *Liquor Potassæ* with each ounce of the freshly prepared ointment. (*Am. Journ. of Pharm.*, xxiii. 123.)

This ointment is employed for the discussion of goitres, scrofulous tumours, and other indolent swellings; and is sometimes preferred to the ointment of iodine, as it does not, like that, discolour the skin.* W.

UNGUENTUM RESINÆ. *Br.* *Ointment of Resin.*

See CERATUM RESINÆ.

UNGUENTUM SABINÆ. *Br.* *Ointment of Savin.*

See CERATUM SABINÆ.

UNGUENTUM STRAMONII. *U. S.* *Ointment of Stramonium.*

"Take of Extract of Stramonium *sixty grains;* Water *half a fluidrachm;* Lard *a troyounce.* Rub the Extract first with the Water until rendered uniformly soft, then with the Lard, and thoroughly mix them." *U. S.*

This is a more certain preparation than that of the former editions of the U. S. Pharmacopœia, which was made by boiling the fresh leaves in lard. For remarks by Mr. A. P. Sharp, of Baltimore, on the preparation of this ointment, see the *American Journal of Pharmacy* (xxvii. 391).

The ointment of Stramonium is a useful anodyne application in irritable ulcers, painful hemorrhoids, and in some cutaneous eruptions. W.

* *Elder Ointment.* UNGUENTUM SAMBUCI, *Lond.* Though omitted in the British Pharmacopœia, we retain this preparation in its present position from its long popularity. The following was the London formula. "Take of Elder [flowers], Lard, each, *two pounds.* Boil the Elder in the Lard till it becomes crisp; then express through linen." Elder flowers impart odour to lard without adding to its virtues. An ointment, prepared in like manner from the leaves, has a green colour, and is popularly employed as a cooling application in England. Mr. Joseph Ince says of the ointment prepared according to the official directions, that it is apt to be somewhat brownish, and to become hard and rancid; but if, after the straining through linen, it be set aside for a few days, and, after deposition and concretion, be filtered through a funnel kept hot with steam, these disadvantages will be obviated. (*Pharm. Journ.*, xiv. 489.)

UNGUENTUM SULPHURIS. *U. S., Br. Ointment of Sulphur.*

"Take of Sublimed Sulphur *a troyounce;* Lard *two troyounces.* Mix them." *U. S.*

"Take of Sublimed Sulphur *one ounce;* Prepared Lard *four ounces.* Mix thoroughly." *Br.*

The U. S. ointment is twice as strong as the British. Sulphur ointment is a specific for the itch. It should be applied every night till the complaint is cured; and it is recommended that only one-fourth of the body should be covered at a time. We have usually directed it to be applied over the whole surface, and have found no inconvenience to result. Four applications are generally sufficient to effect a cure. It is thought by some that powdered roll sulphur is more efficacious than the sublimed. Sulphur ointment, applied freely over the variolous eruption, in its early stage, is said to prevent the maturation of the pustules and consequent pitting. The disagreeable odour of the ointment may be in some measure concealed by a little oil of lemons, or oil of bergamot. W.

UNGUENTUM SULPHURIS IODIDI. *U. S. Ointment of Iodide of Sulphur.*

"Take of Iodide of Sulphur *thirty grains;* Lard *a troyounce.* Rub the Iodide of Sulphur, first reduced to a fine powder, with a little of the Lard, then add the remainder, and thoroughly mix them." *U. S.*

This is admirably adapted, as a local remedy, to the treatment of chronic cutaneous eruptions, unattended with inflammation; and is especially useful in psoriasis, lepra, porrigo, and the very advanced stages of eczema and impetigo, when they have become dry. W.

UNGUENTUM TABACI. *U. S. Ointment of Tobacco.*

"Take of Tobacco, in fine powder, *half a troyounce;* Lard *eight troyounces;* Water *a sufficient quantity.* Moisten the Tobacco with a little Water, introduce it into a conical glass percolator, and, having pressed it firmly, pour Water upon it until four fluidounces of filtered liquid have passed. Evaporate this to the consistence of a soft extract, and mix it thoroughly with the Lard." *U. S.*

In the first edition of the U. S. Pharmacopœia, this ointment, under the name of "Tobacco Liniment," was directed to be prepared by boiling together lard and common dried tobacco; but in this condition the leaves do not yield their virtues to lard. The error was corrected in the second edition, in which fresh tobacco was directed. Though the tobacco plant is not an object of general culture in the Northern States, it may readily be produced in gardens, in quantities sufficient to supply any demand for the fresh leaves.

Fresh narcotic vegetables yield their active principles, and chlorophyll or green colouring matter to oleaginous substances, when heated with them; and ointments have long been prepared in this manner. In the pharmacy of the continent of Europe, olive oil is frequently employed as the solvent, and the resulting preparations are called *olea infusa.* Several of these are ordered by the French Codex, as the oils of henbane, stramonium, tobacco, &c. Lard is preferred in British and American pharmacy, as affording preparations of a more convenient consistence. The boiling takes place at a lower temperature than that necessary for the evaporation of the lard or oil, and is owing to the escape of the watery parts of the plants. It should be continued till all the water is driven off; as this, if allowed to remain, would render the ointment more liable to spontaneous decomposition; and, besides, the colouring matter of the narcotic is not freely extracted till after the dissipation of the water. In the recent revision, however, of the Pharmacopœia, it was thought expedient to discard this method of preparing the ointment altogether, and to substitute a concentrated infusion of the dried leaves mixed with lard. The new preparation is probably quite as efficient as the old, if not more so, while pharmaceutically it is much neater.

Tobacco ointment is useful in irritable ulcers, and various cutaneous eruptions, particularly *tinea capitis;* but great care must be taken, especially in children, not to employ it in such quantities as to endanger the production of the constitutional effects of the narcotic. W.

UNGUENTUM TEREBINTHINÆ. *Br. Ointment of Turpentine.*

"Take of Oil of Turpentine *one fluidounce;* Resin, in coarse powder, *sixty grains;* Yellow Wax, Prepared Lard, each, *half an ounce* [avoirdupois]. Mix the ingredients together by the heat of a steam or water bath. When they are melted, remove the vessel, and stir until the mixture becomes solid." *Br.*

This is a somewhat stronger preparation than the British *Linimentum Terebinthinæ,* but is probably intended for the same purpose, as a dressing, namely, for burns, for which it is sometimes more convenient by its firmer consistence. W.

UNGUENTUM VERATRIÆ. *U. S., Br. Ointment of Veratria.*

"Take of Veratria *twenty grains;* Lard *a troyounce.* Rub the Veratria with a little of the Lard; then add the remainder, and thoroughly mix them." *U. S.*

"Take of Veratria *eight grains;* Prepared Lard *one ounce* [avoirdupois]; Olive Oil *half a fluidrachm.* Rub the Veratria and the Oil together; then mix them thoroughly with the Lard." *Br.*

This ointment has been substituted for the Ointment of White Hellebore of the former edition of the U. S. Pharmacopœia, which was made by rubbing together two ounces of the powdered root, twenty minims of the Oil of Lemons, and eight ounces of Lard, and which has sometimes been employed with advantage in the itch. It is less disagreeable, but also less certain than the sulphur ointment. For the uses of veratria ointment see the article on *Veratria.* It should be noticed that the U. S. ointment is more than twice as strong as the British. It should be employed with caution in children. W.

UNGUENTUM ZINCI OXIDI. *U. S., Br. Ointment of Oxide of Zinc.*

"Take of Oxide of Zinc *eighty grains;* Lard *a troyounce.* Mix them." *U. S.*

"Take of Oxide of Zinc, in very fine powder, *eighty grains;* Simple Ointment *one ounce* [avoirdupois]. Add the Oxide to the Ointment, previously melted with a gentle heat, and stir the mixture constantly until it becomes cold." *Br.*

This is employed as a mild astringent application in chronic ophthalmia with a relaxed state of the vessels, in cutaneous eruptions, and in sore nipples and other instances of excoriation or ulceration. It has taken the place of the discarded *unguentum tutiæ,* or *tutty ointment,* prepared from tutty or the impure oxide of zinc, by mixing it with five parts of simple ointment. W.

VERATRIA.

Veratria.

VERATRIA. *U. S., Br. Veratria.*

"Take of Cevadilla, in moderately fine powder, *twenty-four troyounces;* Alcohol, Sulphuric Acid, Magnesia, Water of Ammonia, Purified Animal Charcoal, Water, each, *a sufficient quantity.* Digest the Cevadilla with eight pints of Alcohol for four hours, in a distillatory apparatus, with a heat approaching to boiling, and pour off the liquid. To the residue add eight pints more of Alcohol, mixed with the portion distilled, and having digested for an hour, pour off the liquid as before. Digest for a third time with the same quantity of Alcohol, together with the portion last distilled, and again pour off. Press the remains of the Cevadilla, mix and strain the liquids, and, by means of a water-bath, distil off the Alcohol. Boil the residue three or four times in Water acidulated with Sulphuric Acid, mix and strain the liquids, and evaporate to the consistence of

syrup. Add Magnesia in slight excess, shake the mixture frequently, then express, and wash what remains. Repeat the expression and washing two or three times, and, having dried the residue, digest it with a gentle heat several times in Alcohol, and strain after each digestion. Distil off the Alcohol from the mixed liquids, boil the residue for fifteen minutes in water mixed with a little Sulphuric Acid and Purified Animal Charcoal, and strain. Having thoroughly washed what remains, mix the washings with the strained liquid, evaporate with a moderate heat to the consistence of thin syrup, and drop in sufficient Water of Ammonia to precipitate the Veratria. Lastly, wash the alkaloid with Water, and dry it with a gentle heat." *U. S.*

"Take of Cevadilla *two pounds* [avoirdupois]; Distilled Water, Rectified Spirit, Solution of Ammonia, Hydrochloric Acid, each, *a sufficiency;* Purified Animal Charcoal *sixty grains.* Macerate the Cevadilla with half its weight of boiling Distilled Water, in a covered vessel, for twenty-four hours. Remove the Cevadilla, squeeze it, and dry it thoroughly with a gentle heat. Beat it now in a mortar, and separate the seeds from the capsules by brisk agitation in a deep narrow vessel, or by winnowing it gently on a table with a sheet of paper. Grind the seeds in a coffee mill, and form them into a thick paste with Rectified Spirit. Pack this firmly in a percolator, and pass Rectified Spirit through it till the Spirit ceases to be coloured. Concentrate the spirituous solution by distillation, so long as no deposit forms; and pour the residue, while hot, into twelve times its volume of cold Distilled Water. Filter through calico, and wash the residue on the filter with Distilled Water, till the fluid ceases to precipitate with Ammonia. To the united filtered liquids add the Ammonia in slight excess, let the precipitate completely subside, pour off the supernatant fluid, collect the precipitate on a filter, and wash it with Distilled Water till the fluid passes colourless. Diffuse the moist precipitate through twelve fluidounces of Distilled Water, and add gradually with diligent stirring sufficient Hydrochloric Acid to make the fluid feebly but persistently acid. Then add the Animal Charcoal; digest at a gentle heat for twenty minutes, filter, and allow the liquid to cool. Add Ammonia in slight excess, and, when the precipitate has completely subsided, pour off the supernatant liquid, collect the precipitate on a filter, and wash it with cold Distilled Water till the washings cease to be affected by nitrate of silver acidulated with nitric acid. Lastly, dry the precipitate first by imbibition with filtering paper, and then on the steam bath." *Br.*

In the U. S. process the first step is to obtain a tincture of cevadilla. In the British process, which is mainly that of the late Edinburgh Pharmacopœia, the use of alcohol is preceded by measures calculated to bring the seeds into a proper state for its action. This is not satisfactorily effected by mere bruising. The seeds are not thus separated from the capsules; and, on account of their elasticity, they cannot be conveniently comminuted in a mortar. The mode of proceeding given in the British Pharmacopœia was suggested by Christison, and is said by him to answer the purpose. In the U. S. process, the tincture, when made, is evaporated to the consistence of an extract. This contains the veratria combined with a vegetable acid, probably the gallic, as it exists in the seeds. From the extract the alkaloid is dissolved by the acidulated water, which at the same time converts it in great measure into a sulphate, a small portion possibly remaining in the solution combined with an excess of the native acid. The magnesia combines with the acids and throws down the veratria, which is then taken up by alcohol, and again yielded in a purer state by evaporation. To purify it still further, it is redissolved in water by the agency of sulphuric acid, is submitted to the action of animal charcoal, and is finally precipitated by ammonia. In the British process, the tincture is concentrated until it begins to let fall a precipitate, and is then poured into water, which throws down the resin and oil with a portion of the colouring matter, and retains the salt of veratria. This is then

decomposed by ammonia, and the precipitated veratria is slightly washed with cold water to free it from adhering impurities. If much water is employed in the washing, a considerable portion of the veratria is lost, in consequence of being in some degree soluble in that menstruum in its ordinary impure state. The remaining steps of the British process consist in the purification of the veratria by forming a muriate in solution, decolorizing this by animal charcoal, and again precipitating by ammonia.*

* Mr. James Beatson, manufacturing chemist of the U. S. Naval Laboratory at New York, recommends the following method of preparing veratria as less complicated and troublesome than the officinal, and quite satisfactory in its results. Take 73 pounds (avoirdupois) of cevadilla, rub it upon a coarse wire sieve so as to separate the seeds from the capsules, and reduce the former to a coarse powder by a Swift's drug mill. Pass the capsules also through the mill, separate the finer portion, and mix it with the ground seeds. Moisten the mixture with alcohol, and allow it to stand 12 hours; then introduce it into a displacement apparatus, and pour upon it 30 gallons of alcohol. When a convenient quantity of the liquid has passed, submit it to distillation, and return the distilled alcohol to the displacement apparatus; and proceed in the same way until the cevadilla is thoroughly exhausted. Collect all the alcoholic liquor from the exhausted seeds, and continue the distillation until the tincture has a syrupy consistence. Pour this while hot into eight times its volume of cold water, throw the whole on a calico filter, and wash until the washings cease to indicate the presence of veratria. Mix the washings with what first passed through the filter, and add aqua ammoniæ in excess (about 4 pounds). Wash the precipitated veratria with cold water, and dry it with a very gentle heat. Mr. Beatson obtained by this process eleven and a quarter ounces of pure veratria, but faintly tinged with colouring matter. (*Am. Journ. of Pharm.*, xxvi. 5.)—*Note to the tenth edition.*

M. Auguste Delondre, in a paper upon veratria in the *Journ. de Pharm.* for June, 1855 (p. 417), having stated that he had found the veratria of commerce to contain only from 75 to 85 per cent. of the pure alkaloid; that in the ordinary modes of obtaining it with the aid of heat, much is lost in consequence of its extreme facility of volatilization; and that the operator is from the same cause exposed to excessive irritation of the air-passages, eyes, &c., from its vapours; proposes the following plan of preparing it as the result of many experiments and long attention to the subject.

The powdered cevadilla is treated, by means of percolation, with cold water slightly acidulated with muriatic acid until the liquid which passes strongly reddens litmus paper, when the percolation is finished with pure water. It is known that the cevadilla has been exhausted, when the last liquid which passes gives no precipitate with ammonia. The liquid thus obtained is precipitated by a slight excess of the ammoniacal solution; the grayish precipitate formed is drained and washed; and the washings as well as the decanted liquid are set aside. The precipitate, having been carefully dried and powdered, is treated, in a well-closed bottle, with twice its weight of ether for four hours, with occasional agitation; and the ethereal solution is filtered upon shallow porcelain vessels, and allowed to evaporate. A second treatment with half the quantity of ether serves to extract all the alkaloid. The veratria is allowed to dry, and is then carefully detached from the plates so as to avoid unpleasant consequences to the operator, and kept for use. M. Delondre considers his process more productive, cheaper, and less inconvenient than the one generally employed; as the injurious effects of heat are avoided, and there are less frequent solutions.

The alkaloid, *veratrin*, being insoluble in ether, is left behind after the operation of that liquid. It is extracted by alcohol, which, on evaporation, yields a brown resinous matter, from which the veratrin may be obtained by heating it with water acidulated with sulphuric acid, and precipitating by ammonia. It exists, however, in very minute proportion, and is difficult to obtain pure. Its effects have not been determined; but its powder produces sneezing, though much less violently than veratria.

The washings and decanted fluid, which had been set aside, yield on evaporation an extract, which, when dried, and treated with ether, gives a little additional veratria: the sabadillin and resini-gum of M. Couerbe remaining behind. If the residue be dissolved in cold water, and the solution filtered and slowly evaporated, a mixture of crystals of sabadillin and resini-gum is obtained, which it is very difficult to separate.

Commercial veratria may be purified with great facility by means of ether, which dissolves the pure alkaloid, leaving the impurities. — *Note to the eleventh edition.*

Dr. Murray Thomson, of Edinburgh, operates in a similar manner with M. Delondre in exhausting the seeds with water, acidulated with muriatic acid, and in precipitating with ammonia; but, instead of exhausting the precipitate with ether, he uses hot alcohol for the purpose, and then proceeds by evaporating the tincture, treating the residue with

The U. S. process is essentially that of M. Couerbe. The veratria obtained by it, though not pure, is sufficiently so for medical use. A drachm of it, in this state, may be procured from a pound of cevadilla. Besides veratria, M. Couerbe states that principles, which he calls respectively *sabadillin* (*sabadillia*) and *veratrin*, are also contained in this product. These are separated in the following manner. Into the solution of impure sulphate of veratria obtained in the above process, nitric acid is to be introduced by drops. This occasions an abundant precipitate, from which the clear liquor is to be decanted. A weak solution of potassa is then to be added to the liquor, and the precipitate which it produces is to be washed with cold water, and treated with boiling alcohol. The substance obtained by evaporating the alcohol yields the *sabadillia* to boiling water, which deposits it upon cooling; a substance, called by M. Couerbe *resini-gum* of sabadilla, remaining in solution. If the residue of the substance, treated as just mentioned with boiling water, be submitted to the action of ether, it yields to this liquid the proper *veratria*, which may be obtained entirely pure by the spontaneous evaporation of the ether. The matter remaining undissolved is the resinous substance which M. Couerbe called *veratrin*. *Sabadillia* is white, crystallizable, insupportably acrid, fusible by heat, readily soluble in hot water, which deposits it upon cooling, very soluble in alcohol, and wholly insoluble in ether. It is capable of saturating the acids. (*Journ. de Pharm.*, xix. 527.) According to Simon, sabadillia is a compound of resinate of soda and resinate of veratria. Fr. Hübschmann confirms the views of Couerbe as to the separate existence of sabadillia. He obtained it by treating the matter considered as veratria with ether, which removed the pure veratria, and left the sabadillia. The latter does not irritate the nostrils like veratria. (*Am. Journ. of Pharm.*, xxv. 133.)

Properties, &c. In the impure state in which it is obtained by either of the above officinal processes, veratria is a grayish or brownish-white powder, without odour, and of a bitter, acrid taste, producing a sense of tingling or numbness in the tongue, and exciting violent sneezing and coryza, when admitted into the nostrils. When pure, it is white, pulverulent, inodorous, extremely acrid, fusible by heat, inflammable, scarcely soluble in cold water, soluble in a thousand parts of boiling water which it renders sensibly acrid, in eleven parts of alcohol of 0·847, and in six parts of ether (Delondre, *Journ. de Pharm.*, xxvii. 421), and capable of neutralizing acids, with several of which, particularly the sulphuric and muriatic, it forms crystallizable salts. As commonly obtained, it is uncrystallizable; but G. Merck, by dissolving it in highly rectified alcohol, and allowing the solution to evaporate spontaneously, obtained fine crystals in the form of rhombic prisms. The quantity obtained in crystals was but a small proportion of the veratria used, which Merck considered to be a mixture of resin with the pure alkaloid, and on this account to be uncrystallizable. (See *Am. Journ. of Pharm.*, xxviii. 134.) The composition of veratria is expressed, according to Couerbe, by the formula $C_{34}H_{22}NO_6$; but Merck, who obtained it crystallized, and therefore pure, gives the formula $C_{64}H_{52}N_2O_{16}$. (*Ibid.*, p. 135.) It may be recognised by its sensible properties, incapacity of crystallization as ordinarily procured, combustibility, fusibility, peculiar solubilities, alkaline reaction, the intense red colour it assumes upon contact with concentrated sulphuric acid, the yellow solution it forms with nitric acid, and the white precipitates which its solution in dilute acetic acid yields with ammonia and the infusion of galls. Chlorine at first colours a solution of its salts

acidulated water, decolorizing with a little animal charcoal, and precipitating with ammonia. The alkaloid thus obtained may be rendered purer by again dissolving and precipitating as before. Dr. Thomson has thus obtained veratria in the proportion of 20 grains to an avoirdupois ounce of the seeds. (*Pharm. Journ.*, May, 1861, p. 548.) It is, however, obvious, from what is said in the preceding note, that the veratria of Dr. Thomson contains veratrin. —*Note to the twelfth edition.*

yellow, and afterwards produces a white precipitate. (*Cent. Blatt*, June 28, 1856, p. 454.) Compound solution of iodine causes a reddish-brown precipitate, soluble in alcohol. (Fairthorne, *Am. Journ. of Pharm.*, xviii. 212.) According to Trapp, of St. Petersburg, the smallest trace of veratria, if dissolved in highly concentrated muriatic acid, gives a solution which, though colourless at first, becomes red by boiling, and intensely red like permanganate of potassa if the boiling be long continued. (See *Am. Journ. of Pharm.*, Nov. 1863, p. 556.) It is entirely dissipated by a red heat. It is said sometimes to be sophisticated with lime, which is easily detected by incineration, and may be separated by dissolving the powder in diluted alcohol, precipitating by sulphuric acid, filtering, evaporating the alcohol, and precipitating the veratria by ammonia. (*Chem. Gaz*, Feb. 1845, p. 73.) Mr. John E. Carter, of Philadelphia, found a specimen which he examined to contain 38 per cent. of magnesia. (*Am. Journ. of Pharm.*, Jan. 1858, p. 16.) It may be used either in the uncombined state, or united with acids; as in both forms it produces essentially the same effects.

Medical Properties and Uses. Veratria is locally irritant, and exercises a peculiar influence on the nervous system. Rubbed upon the skin it excites a sensation of warmth and a peculiar tingling. Sometimes an evanescent blush is produced, and still more rarely an eruption upon the skin; but, in general, no decided signs of inflammation are evinced. Upon the denuded cutis, however, veratria and its salts are powerfully irritating; in the mouth and fauces produce an almost insupportable sense of acrimony; and snuffed up the nostrils excite violent sneezing. Magendie states that, when taken internally in the dose of a quarter of a grain, they promptly produce abundant alvine evacuations, and in larger doses provoke more or less violent vomiting. Other experimenters have observed similar effects. Dr. Turnbull, on the contrary, says that he has very seldom found them to purge, even when largely administered. According to this author, their first effect, when given in moderate doses, is a feeling of warmth in the stomach, gradually extending itself over the abdomen and lower part of the chest, and ultimately to the head and extremities. If the medicine is continued, this feeling of warmth is followed by a sense of tingling, similar to that produced by the external use of the medicine, which manifests itself in different parts of the body, and sometimes over the whole surface, and is frequently accompanied by perspiration and some feeling of oppression. Occasionally also diuresis is produced. A still further continuance of the medicine, or the use of large doses, excites nausea and vomiting. It occasions no narcotic effects. In overdoses it is a violent poison. Dr. J. L. Van Praag has experimented with veratria on the lower animals, and gives as the result of his observations, that it lowers the circulation and respiration, diminishes the irritability of many of the nerves, especially the cutaneous, and produces muscular relaxation; while, at the same time, it frequently vomits, and in large doses purges. The secretion of saliva is much increased, but that of urine little affected. In poisonous doses, before producing the depressing effects above referred to, it accelerates the pulse and respiration, occasions tonic and clonic spasms of the muscles, and exalts the nervous irritability generally. Tetanic stiffening of the limbs, followed by a dancing movement, is a characteristic symptom of poisoning with this alkaloid. Death seems to result from paralysis of the spinal cord. (*B. and F. Medico-Chirurg. Rev.*, July, 1855, Am. ed., p. 185, from *Virchow's Archiv.*)

The diseases in which veratria has been employed are chiefly gout, rheumatism, and neuralgia. M. Piedagnel has used it with great supposed advantage in acute articular rheumatism, which he has found generally to get well under its use in seven or eight days. (See *Am. Journ. of Med. Sci.*, N. S., xxvi. 496.) Dr. Turnbull has found it useful also in dropsy, and in diseases of the heart, particularly those of a functional character. He thinks he has also seen it do good in structural diseases of that organ, but chiefly by acting as a diuretic, and

thereby removing effusion in the pericardium. Prof. Vogt, of Berne, employs it in pneumonia, giving 5 milligrammes (about the thirteenth of a grain) every two hours, and five or six times that amount during the day, increased in insusceptible persons to ten or twelve times the quantity; the dose being continued or increased till vomiting and reduction of the pulse are produced. (See *Am. Journ. of Pharm.*, May, 1860, p. 222.) Veratria has also been employed in dysmenorrhœa, and in various nervous affections, as paralysis, hooping-cough, epilepsy, hysteria, and disorders dependent upon spinal irritation. From one-twelfth to one-sixth of a grain may be given in the form of pill, and repeated every three hours till the effects of the medicine are experienced. Some prefer the salts for internal use. Dr. Turnbull states that the tartrate is least disposed to irritate the stomach. The sulphate or acetate, however, may be used. Any one of these salts may be prepared by treating veratria with water acidulated with the acid to perfect neutralization, and then carefully evaporating to dryness.

But veratria is much more employed externally than by the stomach, and is applicable in this way to all the complaints already mentioned. It has been highly praised as a local application in chronic swellings, stiffening, and induration of the joints, whether from rheumatism, scrofula, or simply from local injuries, as sprains. It may be used either dissolved in alcohol, or rubbed up with lard or other unctuous substance, in the proportion of from five to twenty grains to the ounce. It is advisable that the alkaloid should be dissolved in a little alcohol before being mixed with the lard. Of the ointment thus prepared, a portion of the size of a filbert may be rubbed upon the skin over the part affected, night and morning, from five to fifteen minutes, or until the more urgent symptoms are relieved. Veratria may be used in this way to the amount of from four to eight grains in the day. Care must be taken that the cuticle is sound over the parts to which it is applied. When the skin is irritable, smaller quantities than those above mentioned must be used.

Off. Prep. Unguentum Veratriæ. W

VINA MEDICATA.

Medicated Wines.

The advantages of wine as a pharmaceutic menstruum are that, in consequence of the alcohol it contains, it dissolves substances insoluble in water, and, to a certain extent, resists their tendency to spontaneous change; while, at the same time, it is less stimulant than rectified or proof spirit, both from its smaller proportion of alcohol, and from the modified state in which this fluid exists in its composition. The acid which it usually contains serves in some instances to increase its solvent power. But most wines, particularly the light varieties, are liable to undergo decomposition; and even the strongest acquire such a liability from the principles which they extract from vegetable substances; so that medicated wines, though they keep much better than infusions or decoctions, are inferior in this respect to the tinctures. The proportion of alcohol, moreover, is not constant; and the preparations, therefore, made with them, are of unequal strength. From these causes, few medicated wines are at present retained. In the choice of wine, the purest and most generous should be selected. Sherry, as directed by the U. S. and British Pharmacopœias, Teneriffe, or Madeira should be preferred. The medicated wines, in consequence of their liability to change, should be prepared in small quantities, without heat, and should be kept in well-stopped bottles in a cool place.

The Wines, formerly officinal, which have been omitted in the present Pharmacopœias, are *Vinum Gentianæ*, Ed., and *Vinum Veratri Albi*, U. S., Lond. W

VINUM ALOES. *U. S., Br. Wine of Aloes.*

"Take of Socotrine Aloes, in fine powder, *a troyounce;* Cardamom [seeds], in moderately fine powder, Ginger, in moderately fine powder, each, *sixty grains;* Sherry Wine *a pint.* Macerate for seven days, with occasional agitation, and filter through paper." *U. S.*

"Take of Socotrine Aloes *one ounce and a half* [avoirdupois]; Cardamoms, ground, Ginger, in coarse powder, of each, *eighty grains;* Sherry *two pints* [Imperial measure]. Digest for seven days, and strain through calico." *Br.*

The wine of aloes is a warm stomachic purgative, useful in constipation dependent on a want of due irritability of the alimentary canal, and in complaints connected with this state of the bowels. It has long been used in chlorosis, amenorrhœa, dyspepsia, gout, paralysis, &c. It is said to leave behind it a more lax condition of the bowels than most other cathartics. The dose as a stomachic is one or two fluidrachms, as a purgative from half a fluidounce to a fluidounce. W.

VINUM ANTIMONII. *U. S.* VINUM ANTIMONIALE. *Br. Antimonial Wine. Wine of Antimony.*

"Take of Tartrate of Antimony and Potassa *thirty-two grains;* Boiling Distilled Water *a fluidounce;* Sherry Wine *a sufficient quantity.* Dissolve the Salt in the Distilled Water, and, while the solution is hot, add sufficient Sherry Wine to make it measure a pint." *U. S.*

"Take of Tartarated Antimony *forty grains;* Sherry *one pint* [Imperial measure]. Dissolve." *Br.*

In the first edition of the United States Pharmacopœia, the proportion of tartar emetic was four grains to the fluidounce of wine. In the revision of 1830, the quantity was reduced to two grains, and, as this was very nearly the proportion directed by the British Colleges, the highly important object was accomplished, of uniformity in the strength of this very popular preparation. The seeming discrepancy between the British formula, and that of the U. S. Pharmacopœia will disappear, when it is considered that the Imperial pint, employed in the former, contains twenty fluidounces, each very nearly equal to the fluidounce of the ordinary apothecaries' measure. The U. S. officinal name was adopted as most convenient, sufficiently expressive, and in accordance with the nomenclature of several other metallic preparations, such as *Emplastrum Ferri, Mistura Ferri Composita, &c.*

Difficulty is often experienced in effecting a solution of tartar emetic in wine; and precipitation is apt to occur after the solution has been effected. These results are attributable either to impurity in the antimonial salt, which frequently contains bitartrate of potassa and various insoluble substances, or to inferiority in the character of the wine, which holds in solution vegetable principles that form insoluble compounds with the teroxide of antimony. Dr. Paris states that he has seen the decomposition of the tartar emetic so complete, that no traces of the salt could be detected in the supernatant liquid. The difficulty is not avoided by the plan adopted in the U. S. Pharmacopœia, of first dissolving the antimonial in water, and then adding the wine; for, even allowing that the solution may be accomplished, the same ingredients are present, and their mutual reaction must ultimately result in the same effects. The proper course is to select perfectly pure crystallized tartar emetic, and sound Sherry or Teneriffe wine, which make a permanent solution. To obviate the risk of decomposition, the Dublin College directed water and rectified spirit in about the proportion in which these exist in the wines just mentioned. The only objection to this menstruum is the want of colour, which renders the preparation liable to be confounded with less active liquids.

The advantages of antimonial wine are, that it affords the means of adminis-

tering minute doses of tartar emetic, and is more permanent than an aqueous solution of that salt, which is liable to spontaneous decomposition. It is usually administered in small doses as a diaphoretic or expectorant, or as an emetic in infantile cases. When a considerable quantity of tartar emetic is requisite, it should always be given in extemporaneous aqueous solution. The dose of the wine, as an expectorant or diaphoretic, is from ten to thirty drops, given frequently; as an emetic for children, from thirty drops to a fluidrachm, repeated every fifteen minutes till it operates.

Off. Prep. Mistura Glycyrrhizæ Composita, *U. S.* W.

VINUM COLCHICI RADICIS. *U. S.* Vinum Colchici. *Br.* *Wine of Colchicum Root.*

"Take of Colchicum Root, in moderately fine powder, *twelve troyounces;* Sherry Wine *a sufficient quantity.* Moisten the powder with four fluidounces of Sherry Wine, pack it firmly in a conical percolator, and gradually pour Sherry Wine upon it until two pints of filtered liquid are obtained." *U. S.*

"Take of Colchicum Corm, dried and sliced, *four ounces* [avoirdupois]; Sherry *one pint* [Imperial measure]. Macerate the Colchicum in the Wine for seven days, press and strain through calico; pour on the marc sufficient Sherry to make up one pint [Imp. meas.], and, having pressed and strained as before, mix the fluids." *Br.*

This is intended to be a saturated vinous tincture of colchicum. As the colchicum bulb imported into the United States is of variable strength, the only method by which an active preparation can be ensured, is to employ a large quantity of it in proportion to that of the menstruum. If the former should happen to be in excess, no other injury could result than a slight pecuniary loss; while a deficiency in the strength of the preparation would frequently be of serious detriment in urgent cases of disease. A wine made from the fresh bulb is occasionally imported from England, and is thought by some to be more efficacious than our officinal preparation; but we have seldom been disappointed in obtaining the effects of colchicum from the wine prepared according to the directions of the U. S. Pharmacopœia. The dose of the officinal wine is from ten minims to a fluidrachm, repeated three or four times a day, or more frequently in severe cases, till its effects are experienced. In gout it is frequently given in connection with magnesia and its sulphate; and in neuralgic cases we have found much advantage from combining it with the solution of sulphate of morphia, especially when we have desired to give it a direction rather to the skin than the bowels. It has been employed externally with asserted advantage in rheumatism. In overdoses it may produce fatal effects. Death is said to have occurred in one instance from two drachms and a half of the wine; but much more would probably in general be requisite to produce this result. W.

VINUM COLCHICI SEMINIS. *U. S.* *Wine of Colchicum Seed.*

"Take of Colchicum Seed, in moderately coarse powder, *four troyounces;* Sherry Wine *two pints.* Macerate for fourteen days, with occasional agitation; then express, and filter through paper." *U. S.*

As the seeds of colchicum are less liable to injury than the bulb, and are, therefore, of more uniform strength, there is not the same necessity for preparing a saturated tincture. Dr. Williams, who introduced the seeds into use, supposed that their active properties resided in their coating, and that it was, therefore, not advisable to bruise them in preparing the wine or tincture. But this has been shown to be an error by the experiments of Mr. Bonnewyn, who found a larger proportion of colchicia in a tincture of the bruised than in one of the unbruised seeds. (See *Am. Journ. of Pharm.*, xxvi. 120.) In order that the seeds may be properly comminuted, Mr. Maisch recommends that they should be macerated for two or three days in a portion of the wine, before being bruised.

(*Ibid.*, xxviii. 514.) The dose is from thirty minims to two fluidrachms. Two fluidounces have proved fatal. W.

VINUM ERGOTÆ *U. S. Wine of Ergot.*

"Take of Ergot, in moderately fine powder, *four troyounces;* Sherry Wine *a sufficient quantity.* Moisten the powder with half a fluidounce of Sherry Wine, pack it in a conical percolator, and gradually pour Sherry Wine upon it until two pints of filtered liquid are obtained." *U. S.*

In a certain number of copies of the existing edition of the U. S. Pharmacopœia first issued from the press, *two* troyounces of the ergot were, no doubt inadvertently, directed instead of *four;* the intention being that the Wine should continue to have the same strength as that of 1850, in the preparation of which two ounces were directed; but the fact being overlooked that the quantity of the menstruum was only one pint, while in the present formula it is two pints. The error, however, was corrected; and in the copies now issued four ounces are ordered, as above stated. The large proportion of fixed oil in ergot interferes with the solvent action of the menstruum, unless the grains are finely powdered. It is, therefore, best to employ the ergot in this process well powdered, instead of merely bruised, as was formerly officinally directed.

The dose of this wine is for a woman in labour two or three fluidrachms; for other purposes, one or two fluidrachms, to be repeated several times a day, and gradually increased if necessary. W.

VINUM FERRI. *Br. Wine of Iron.*

"Take of Tartarated Iron *one hundred and sixty grains;* Sherry *one pint* [Imperial measure]. Dissolve." *Br.*

This is simply a vinous solution of tartrate of iron and potassa, and is the most convenient form of this preparation. It is in fact this salt which is formed when wine is made to react on metallic iron; the metal being oxidized and then uniting with the excess of acid of the bitartrate, which is the characteristic salt of wines. The dose of the wine of iron is one or two fluidounces. W.

VINUM IPECACUANHÆ. *U. S., Br. Wine of Ipecacuanha.*

"Take of Ipecacuanha, in moderately fine powder, *two troyounces;* Sherry Wine *a sufficient quantity.* Moisten the powder with half a fluidounce of Sherry Wine, pack it moderately in a conical percolator, and gradually pour Sherry Wine upon it until two pints of filtered liquid are obtained." *U. S.*

"Take of Ipecacuan, bruised, *one ounce* [avoirdupois]; Sherry *one pint* [Imperial measure]. Macerate for seven days, with occasional agitation, express and filter." *Br.*

The preparations of the two Pharmacopœias are not of the same strength; the U. S. wine containing the virtue of 30 grains, the British of only somewhat more than 20 grains in a fluidounce. In the preparation of the British Pharmacopœia, the strength of this wine was reduced almost one-third. Wine of ipecacuanha possesses all the medical properties of the root, and may be used as a substitute when it is desirable to administer the medicine in the liquid form. As it is milder, without being less efficacious than antimonial wine, it is in some instances preferable as an emetic for infants, especially when the antimonial, as not unfrequently happens, is disposed to irritate the bowels. It is much used as an expectorant and diaphoretic; and the effects of the Dover's powder may be obtained by combining it with laudanum, or other liquid preparation of opium. The dose as an emetic for an adult is a fluidounce; as an expectorant and diaphoretic, from ten to thirty minims. A fluidrachm may be given as an emetic to a child one or two years old, and repeated every fifteen minutes till it operates. W.

VINUM OPII. *U. S., Br. Wine of Opium. Sydenham's Laudanum*

"Take of Opium, dried, and in moderately fine powder, *two troyounces;* Cin

namon, in moderately fine powder, Cloves, in moderately fine powder, each, *sixty grains;* Sherry Wine *a sufficient quantity.* Mix the powders with fifteen fluidounces of Sherry Wine, and macerate for seven days, with occasional agitation; then transfer the mixture to a conical percolator, and, when the liquid has passed the surface, gradually pour on Sherry Wine until a pint of filtered liquid is obtained." *U. S.*

"Take of Opium, in powder, *one ounce and a half* [avoirdupois]; Sherry *one pint* [Imperial measure]. Macerate for seven days, strain, express and filter; then add sufficient Sherry to make one pint [Imp. meas.]." *Br.*

The wine made according to the directions of the U. S. Pharmacopœia is a saturated vinous tincture of opium. It contains about the same proportions of the ingredients as the *laudanum of Sydenham,* from which it differs only in wanting a drachm of saffron. The aromatic additions are thought to adapt it to certain states of the stomach or system, in which laudanum is found to produce unpleasant effects. On being long kept it deposits insoluble matter, a sample of which M. Bihot, of Malines, has shown to consist mainly of narcotina, with possibly a little codeia, without any discoverable trace of morphia. (*Journ. de Pharm.*, xxx. 200.) Mr. Ware recommended it as a local application to the eye, in the latter stages of ophthalmia, when the vessels of the conjunctiva still remain turgid with blood. Two or three drops are introduced into the eye every morning till the redness disappears. The dose of the wine of opium is the same as that of the tincture.* W.

VINUM RHEI. *U. S. Wine of Rhubarb.*

"Take of Rhubarb, in moderately coarse powder, *two troyounces;* Canella, in moderately fine powder, *sixty grains;* Sherry Wine *fourteen fluidounces:* Diluted Alcohol *a sufficient quantity.* Mix two fluidounces of Diluted Alcohol with the Sherry Wine, and moisten the powders, previously rubbed together, with half a fluidounce of the mixture; then transfer them to a conical percolator, and gradually pour upon them the remainder of the mixture, and afterwards Diluted Alcohol until a pint of filtered liquid is obtained." *U. S.*

This is a warm cordial laxative, applicable to debilitated conditions of the system or alimentary canal requiring evacuation of the bowels. The dose is from one to four fluidrachms or more, according to the amount of effect required, and the condition of the patient. W.

VINUM TABACI. *U. S. Wine of Tobacco.*

"Take of Tobacco, in moderately fine powder, *a troyounce;* Sherry Wine *a pint.* Macerate for seven days, with occasional agitation; then express, and filter through paper." *U. S.*

The dose of the wine of tobacco, as a diuretic, is from ten to thirty minims. It is very seldom used. W.

ZINCUM.

Preparations of Zinc.

Of the officinal Preparations of Zinc formerly treated of under this head, *Sulphate of Zinc* has been transferred to the Materia Medica, and *Prepared*

* *Rousseau's laudanum* is a tincture of opium made with very weak alcohol, which may be classed with propriety along with the above preparation. It is made according to the following formula. "Take of white honey *twelve ounces;* warm water *three pounds.* Having dissolved the honey, set the solution aside in a warm place; and, as soon as fermentation begins, add of selected opium *four ounces,* previously dissolved in *twelve ounces* of water. Allow the mixture to stand for a month at the temperature of 24° Reaumur (86° F.); then strain, filter, and evaporate to *ten ounces;* finally strain, and add *four ounces and a half* of alcohol of 20° B. Seven drops contain about a grain of opium." (*Pharmacop. Univers.*, ii. 265.)

Calamine, U. S., Lond., Ed., and *Solution of Chloride of Zinc*, Dub., have been omitted in the present Pharmacopœias.

ZINCI ACETAS. *U. S.*, *Br.* *Acetate of Zinc.*

"Take of Acetate of Lead *twelve troyounces;* Zinc, granulated, nine *troyounces;* Distilled Water *a sufficient quantity.* Dissolve the Acetate of Lead in three pints of Distilled Water, and filter. Then add the Zinc to the solution, and agitate the mixture occasionally, in a stopped bottle, for five or six hours, or until the liquid yields no precipitate with a solution of iodide of potassium. Filter the liquid, evaporate it with a moderate heat to one-fifth, acidulate it slightly with acetic acid, and set it aside to crystallize. Pour off the liquid, and dry the crystals on bibulous paper. Should the crystals be coloured, dissolve them in a pint and a half of Distilled Water, and, having heated the solution to ebullition, drop into it, while boiling, recently precipitated carbonate of zinc, in successive portions, until a small quantity of the liquid, being filtered, passes colourless. Then filter the liquid, acidulate it slightly with acetic acid, and evaporate that crystals may form." *U. S.*

"Take of Carbonate of Zinc *two ounces* [avoirdupois]; Acetic Acid *five fluidounces*, or *a sufficiency;* Distilled Water *six fluidounces.* Add the Carbonate of Zinc in successive portions to three [fluid]ounces of the Acetic Acid, previously mixed with the Water in a flask; heat gently, add by degrees the remainder of the Acid till the carbonate is dissolved; boil for a few minutes, filter while hot, and set it aside for two days to crystallize. Decant the mother-liquor; evaporate to one-half, and again set it aside for two days to crystallize. Place the united crystals in a funnel to drain, then spread them on filtering paper on a porous brick, and dry them by exposure to the air at ordinary temperatures." *Br.*

In the *U. S.* process the lead is wholly precipitated by the zinc, which forms with the acetic acid the acetate of zinc in solution. In order to be sure that the solution is entirely free from lead, it is tested with iodide of potassium, which will produce a yellow precipitate if any of the lead remain unprecipitated. The crystals of acetate of zinc, as first obtained, are apt to be coloured with iron. Should this be the case, a boiling solution of them in distilled water is to be treated by the addition of successive portions of precipitated carbonate of zinc, until a small quantity of the liquid, being filtered, passes colourless. The zinc of the carbonate of zinc precipitates the iron, and takes its place in the solution; and the iron is known to be all removed, when a portion of the solution is found, upon trial, to filter colourless. This mode of purifying the acetate of zinc from iron was suggested by Professor Procter, and was adopted in the U. S. Pharmacopœia of 1850, in place of the mode by means of a solution of chlorinated lime, which he found to separate the iron imperfectly. The necessary carbonate of zinc may be obtained extemporaneously, by converting one-thirtieth of the coloured solution of the acetate into carbonate by precipitating it with carbonate of potassa in slight excess, as originally proposed by Prof. Procter. The precipitated carbonate, first washed from acetate of potassa, is added in the state of magma to the coloured solution, boiling hot. During the evaporation of the solution of the acetate of zinc, a small portion of the acetic acid is lost; and hence the necessity of acidulating with a few drops of acetic acid before crystallizing. In the *British* process, there is simply a decomposition of the carbonate of zinc by acetic acid, with the formation of acetate of zinc in solution, and the escape of carbonic acid. Though not an economical process, it has the recommendation of being easily performed, and of yielding a pure product. In relation to the acetate of zinc, see a paper by Mr. Ambrose Smith, contained in the *Amer. Journ. of Pharm.* (vii. 14).

Properties, &c. Acetate of zinc, when carefully crystallized, is in colourless hexagonal plates, which effloresce in a dry air. As found in the shops it is in

white micaceous crystals. It is very soluble in water, moderately so in rectified spirit, and has an astringent, metallic taste. The solution yields white precipitates with ferrocyanide of potassium and hydrosulphuret of ammonia. The precipitate thrown down by ammonia from the pure salt is entirely redissolved by an excess of the precipitant; but, if sesquioxide of iron be present, it will be left undissolved. Acetate of zinc is decomposed by the mineral acids, with the escape of acetous vapours. It consists of one eq. of acetic acid 51, one of protoxide of zinc 40·3, and two of water 18 = 109·3 ($ZnO,C_4H_3O_3 + 2HO$).

Medical Properties. Acetate of zinc is used almost exclusively as a local remedy. It is employed principally as an astringent collyrium in ophthalmia, and as an injection in gonorrhœa, after the acute stage in these affections has passed. The strength of the solution, usually prescribed, is one or two grains to a fluidounce of distilled water. B.

ZINCI CARBONAS PRÆCIPITATA. *U. S.* Zinci Carbonas. *Br.* *Precipitated Carbonate of Zinc. Carbonate of Zinc.*

"Take of Sulphate of Zinc, Carbonate of Soda, each, *twelve troyounces;* Water *eight pints.* Dissolve the salts separately, with the aid of heat, each in four pints of the Water. Then mix the solutions, and, having stirred the mixture, set it by that the powder may subside. Lastly, having poured off the supernatant liquid, wash the precipitate with hot water until the washings are nearly tasteless, and dry it with a gentle heat." *U. S.*

"Take of Sulphate of Zinc *ten ounces* [avoirdupois]; Carbonate of Soda *ten ounces and a half* [avoird.]; Boiling Distilled Water *a sufficiency.* Dissolve the Carbonate of Soda with a pint [Imperial measure] of the Water in a capacious porcelain vessel, and pour into it the Sulphate of Zinc also dissolved in a pint [Imp. meas.] of the Water, stirring diligently. Boil for fifteen minutes after effervescence has ceased; and let the precipitate subside. Decant the supernatant liquor, pour on the precipitate three pints of boiling Distilled Water, agitating briskly; let the precipitate again subside; and repeat the processes of affusion of hot Distilled Water and subsidence, till the washings are no longer precipitated by chloride of barium. Collect the precipitate on calico, let it drain, and dry it with a gentle heat." *Br.*

In view of the impurities and frequent falsification of the native carbonate of zinc, the revisers of the U. S. Pharmacopœia conceived that it would be best to discard altogether the old preparation, which in the edition of 1850 was still retained under the changed name of *Calamina*, and to recognise exclusively the new one first adopted in 1850. In the U. S. formula a double decomposition takes place between the salts employed, resulting in the formation of sulphate of soda in solution, and carbonate of zinc which precipitates. Carbonate of soda is preferable to carbonate of potassa for decomposing the sulphate; since the former gives rise to sulphate of soda, which is more easily washed away than sulphate of potassa, derived from the latter. Boiling water is properly used in the process, in order to obtain a pulverulent precipitate, which is readily washed. If cold solutions are used, a gelatinous precipitate is formed, which is washed with difficulty. The present *British* formula is essentially the same with that of the U. S. Pharm., having superseded the Dublin process, in which the reacting salts were chloride of zinc and carbonate of soda.

Properties, &c. Precipitated carbonate of zinc is in the form of a very soft, loose, white powder, resembling magnesia alba. It dissolves in dilute sulphuric acid with effervescence, forming a solution having the characters of a solution of sulphate of zinc. If adulterated with chalk, it will be only partly soluble in this acid. Precipitated carbonate of zinc is often sold under the incorrect name of flowers of zinc, a name which properly belongs only to the oxide, as obtained by combustion. When obtained from boiling solutions of sulphate of zinc and carbonate of soda, it has the composition, according to Schindler and Lefort,

$8ZnO,3CO_2 + 6HO$. (*Journ. de Pharm.*, *3e sér.*, xi. 329.) According to the Br. Pharmacopœia, it consists, as thus prepared, of one eq. of carbonate and two eqs. of oxide of zinc, with three eqs. of water $(ZnO,CO_2 + HO) + 2(ZnO.HO)$. The basic character of the salt is explained by the fact that effervescence of carbonic acid takes place on mixing the solutions. It is employed for the same purposes as prepared calamine, and is gradually superseding the spurious article usually sold under that name. The U. S. Pharmacopœia orders a cerate made from it as a substitute for calamine cerate. (See *Ceratum Zinci Carbonatis.*)

Off. Prep. Zinci Acetas, *Br.;* Ceratum Zinci Carbonatis, *U. S.;* Zinci Chloridum, *Br.;* Zinci Oxidum; Zinci Sulphas, *Br.* B.

ZINCI CHLORIDUM. *U. S.*, *Br. Chloride of Zinc. Butter of Zinc.*

"Take of Zinc, in small pieces, *two troyounces and a half;* Nitric Acid, Prepared Chalk, each, *sixty grains;* Muriatic Acid, Water, each, *a sufficient quantity.* To the Zinc, in a glass or porcelain vessel, add gradually sufficient Muriatic Acid to dissolve it; then strain the solution, add the Nitric Acid, and evaporate to dryness. Dissolve the dry mass in five fluidounces of the Water, add the Chalk, and allow the mixture to stand for twenty-four hours. Then filter into an evaporating basin, and again evaporate to dryness. Lastly, fuse the dry mass in the basin, pour out the liquid on a flat stone, and, when it has congealed, break the mass in pieces, and keep the fragments in a well-stopped bottle." *U. S.*

"Take of Granulated Zinc *sixteen ounces* [avoirdupois]; Hydrochloric Acid *forty-four fluidounces* [Imperial measure]; Solution of Chlorine *a sufficiency;* Carbonate of Zinc *half an ounce* [avoird.], or *a sufficiency;* Distilled Water *one pint* [Imp. meas.]. Put the Zinc into a porcelain basin, add by degrees the Hydrochloric Acid previously mixed with the Water, and aid the action by gently warming it on a sand-bath until gas is no longer evolved. Boil for half an hour, supplying the water lost by evaporation, and allow it to stand on a cool part of a sand-bath for twenty-four hours, stirring frequently. Filter the product into a gallon bottle, and pour in the Solution of Chlorine by degrees, with frequent agitation, until the fluid acquires a permanent odour of chlorine. Add the Carbonate of Zinc, in small quantities at a time, and with renewed agitation, until a brown sediment appears. Filter through paper into a porcelain basin, and evaporate until a portion of the liquid, withdrawn on the end of a glass rod and cooled, forms an opaque white solid. Pour it out now into proper moulds, and when the salt has solidified, but before it has cooled, place it in closely stoppered bottles." *Br.*

In the U. S. process the chloride of zinc is first formed in solution by dissolving zinc in muriatic acid. The nitric acid added sesquioxidizes any iron which may have existed as an impurity in the zinc. By evaporating to dryness and redissolving in water, most of the sesquioxide of iron is left behind. Lastly, in order to remove any remains of iron, a small portion of chalk is added, which precipitates it as a sesquioxide; and the mixture, after standing, is filtered and evaporated to dryness. This process is the same as that of the French Codex. The British agrees with the U. S. process in first preparing the chloride of zinc in solution; but differs in the mode of getting rid of the iron. Instead of nitric acid it uses chlorine, which combines with the iron to form a chloride; and, carbonate of zinc being then added, the zinc combines with the chlorine to increase the product of chloride of zinc, while the oxygen of the oxide of zinc, the carbonic acid, and the iron unite as the carbonate of iron, which is deposited. As this preparation is used chiefly as a caustic, it is melted and cast into moulds as the last step in both processes. In relation to this chloride, the reader is referred to a paper by Mr. B. J. Crew in the *Am. Journ. of Pharm.*, May, 1853, p. 203.

M. Rhighini prepares this chloride by double decomposition between solutions of chloride of barium and sulphate of zinc. Sulphate of baryta is precipi-

tated, and chloride of zinc remains in solution, from which it is obtained in white flaky crystals by due evaporation.

Properties. Chloride of zinc is a grayish-white, translucent, deliquescent substance having the softness of wax. When pure, it is wholly soluble in water alcohol, and ether; but, as prepared by the U. S. formula, it contains some oxychloride, which is left undissolved by water. According to M. Lassaigne, commercial chloride of zinc sometimes contains as much as 12 per cent. of arseniate of zinc, which, being insoluble in solution of chloride of zinc will be left undissolved, when the chloride is treated with water. (*Phillips's Trans. of the Lond. Pharm.*, 1851, p. 375.) Its solution yields with nitrate of silver a white precipitate (chloride of silver) insoluble in nitric acid; and with ammonia and potassa a white precipitate, soluble in those reagents when added in excess. The carbonates of potassa and soda also throw down a white precipitate, which is not dissolved by an excess of the precipitants. When exposed to heat chloride of zinc first melts and then sublimes. When pure it gives white precipitates with ferrocyanide of potassium and hydrosulphuret of ammonia. A blue precipitate with the former test would indicate iron, a black one with the latter, lead. It consists of one eq. of zinc 32·3, and one of chlorine 35·5 = 67·8.

Medical Properties and Uses. This chloride was introduced into medicine by Dr. Papenguth, of St. Petersburg, and subsequently recommended by Prof. Hancke, of Breslau, and Dr. Canquoin, of Paris. Internally it has been given as an alterative and antispasmodic in scrofula, epilepsy, chorea, and, combined with hydrocyanic acid, in facial neuralgia. Its chief use, however, has been as an escharotic, applied to cancerous affections, and to ulcers of an anomalous and intractable character. When thus used, it not only destroys the diseased structure, but excites a new action in the surrounding parts. As a caustic it has the advantage of not causing constitutional disorder from absorption, an effect which is sometimes produced by the arsenical preparations.

Dr. Canquoin prepares the chloride of zinc, as an escharotic, by thoroughly and quickly mixing it with wheat flour and water into a paste of four different strengths, containing severally an ounce of the chloride, incorporated with two, three, four, and five ounces of flour; fifteen drops of water being added for every ounce of flour, or sufficient to form the paste. It is applied in cakes from a twelfth to a third of an inch in thickness, and produces an eschar more or less deep (from a line to an inch and a half), according to the thickness of the paste, the length of the application, and the nature of the part acted on. The strongest paste is applied to lardaceous and fibro-cartilaginous structures; the second to carcinomatous tumours, and very painful cancers which have not much thickness, and the third to cancerous affections in persons who have a dread of the use of the knife. These preparations, applied to the skin denuded of its cuticle by means of a blister, excite in a few minutes a sensation of heat, and afterwards violent burning pain. The eschar, which is white, thick, and very hard, falls off, with the aid of an emollient poultice, between the eighth and twelfth days. To destroy thick cancerous tumours, having an uneven surface, and situated in fleshy parts, Dr. Canquoin uses a caustic formed of one part of chloride of zinc, half a part of chloride of antimony, and two and a half parts of flour, made into a paste with water. In all cases, the caustic is to be reapplied, after the falling off of the eschar, until the whole morbid structure is destroyed. When the skin is unbroken, it is now usual to destroy, not merely the cuticle, but the true skin also, by means of the acid nitrate of mercury, to the extent desired for the chloride to operate. This is applied, spread on lint, and the dressing is covered with a portion of cotton wadding, to absorb any discharge, and to preserve a uniform temperature. The surrounding skin should be protected from the caustic by a thickly spread dressing of simple cerate, containing as much chloroform as it will take up, as recommended by Dr. E. S. Haviland, of London. M. Bonnet

has applied the paste of chloride of zinc to the treatment of aneurism. He has reported the complete cure of one case of subclavian aneurism from a penetrating wound, by a continued series of applications of the paste. Every two or three days, the superficial layers of the slough were removed by a bistoury. At the end of the second month, the eschar began to detach itself without any hemorrhage, and the clot came away with the eschar. Chloride of zinc has also been used successfully by MM. Bonnet and Gensoul in the treatment of aneurism by anastomosis. (*Med. Times and Gaz.*, July 23, 1853.) Instead of flour, Dr. Alex. Ure, of Glasgow, mixes the chloride with pure anhydrous sulphate of lime in impalpable powder. He states that this has the advantages of furnishing a porous medium from which the escharotic gradually exudes into the morbid structure, and of forming afterwards, by acquiring a firmer consistence, an impervious case for the eschar. Mr. Cock, of Guy's Hospital, has imitated this mode of preparing the chloride, so as to form a caustic which may be limited in its action, and does not run. It may be prepared as a caustic seton, by thickly covering a waxed cotton wick with Dr. Canquoin's caustic paste, and then rolling it out in the form of a cylinder, according to the plan of M. Ancrénis, of Lyons. A thread is wound spirally round the cylinder to give it firmness. Mr. Calloway, of Guy's Hospital, has employed the chloride of zinc with considerable success in the treatment of nævi materni. He rubs it, at intervals, on the part until the skin becomes slightly discoloured. The late Mr. Guthrie used it with advantage for penetrating the hard case of new bone which forms over a sequestrum, in order to expose the latter, and permit its convenient extraction.

Chloride of zinc is an ingredient in the complex caustic formed of chlorides, employed by Prof. Landolfi, of Naples, in the treatment of cancer. For his formula, see *page* 173. This treatment was reported on unfavourably, in 1856, by a committee of the French Academy of Medicine, headed by M. Broca. (See *Ranking's Abstract*, No. 24, p. 100.) The cancer caustic of Dr. J. W. Fell consists of chloride of zinc, mixed with bloodroot, and made into a paste with flour and water. It is not supposed that the bloodroot has any decided caustic effect; so that the local treatment of cancer by Dr. Fell is virtually the same as that recommended in certain cases by Dr. Canquoin.

Chloride of zinc, with a view to its escharotic effect, may be formed extemporaneously by means of *galvanism*, on the plan recommended by an English physician, Dr. Thomas Smith. A simple galvanic circle is formed by riveting a disc of zinc, of the size of the eschar desired, to a disc of silver of equal size; the pair being excited by a piece of spongio-piline, placed on the silver, and moistened with a solution of common salt. The little battery is then fixed upon the skin by means of strips of adhesive plaster. Once in twelve hours it must be removed, and washed in salt and water, and then reapplied. By the electrolysis of the common salt chlorine is liberated, which, combining with the zinc, converts it to a certain extent into the chloride. This, acting on the skin, exercises its caustic effect; and at the end of twelve days a white eschar is formed. This mode of forming an issue has, according to Dr. Smith, the advantage of being less painful than those usually employed.

According to M. E. Robiquet, chloride of zinc may be made into a very malleable, pliable caustic, susceptible of taking any shape desired by the surgeon, by melting it with an equal weight of gutta percha. (See *page* 433.)

For internal exhibition, the most convenient form is a solution in the spirit of ether, in the proportion of half an ounce to three fluidounces. Of this from four to eight drops may be given twice a day. Dr. Lloyd, of London, has found chloride of zinc useful as an injection in the acute stage of gonorrhœa, made of the strength of about two grains to three fluidounces of distilled water, and employed once in five or six hours. A solution of one grain to the fluidounce is used by Mr. Critchett, of the Royal Ophthalmic Hospital, London, as a colly-

rium in cases of vascular and thickened conjunctiva, forming a sort of gleet of the eye.

In overdoses chloride of zinc acts as a corrosive poison, producing burning pain in the gullet and stomach, nausea and vomiting, cold sweats, depression of the pulse, and cramps of the legs. According to Dr. T. Stratton, surgeon R. N., who treated two cases of poisoning with this chloride at Montreal, the best antidotes are the carbonated alkalies, which act by converting the poison into carbonate of zinc. Should the alkalies not be at hand, a solution of common soap should be immediately and freely given. (*Med. Exam.*, Feb. 1849, from the *Brit. Am. Journ. of Med. and Phys. Sci.*) Dr. Letheby reports a fatal case of poisoning by this chloride occurring in a child. The form of chloride swallowed was Burnett's disinfecting fluid. (See the next article.) Its local effect was that of a corrosive on the lips, mouth, and fauces. Among the constitutional effects were paralysis of the voluntary muscles, coldness of the surface dilated pupil, and coma.* B.

* *Solution of Chloride of Zinc. Zinci Chloridi Liquor.* This was officinal in the late Dublin Pharmacopœia, with the following formula.

"Take of Sheet Zinc *one pound* [avoirdupois]; Muriatic Acid of Commerce, Water, of each, *two pints and a half* [Imperial measure], or *as much as may be sufficient;* Solution of Chlorinated Lime *one fluidounce* [Imp. meas.]: Prepared Chalk *one ounce* [avoird.]. To the Zinc, introduced into a porcelain capsule, gradually add the Muriatic Acid, applying heat until the metal is dissolved. Filter the liquid through calico, and, having added to it the Solution of Chlorinated Lime, concentrate at a boiling temperature, until it occupies the bulk of one pint [Imp. meas.]. Permit the solution now to cool down to the temperature of the air, place it in a bottle with the Chalk, and, having first added Distilled Water, so that the bulk of the whole may be a quart [two pints, Imp. meas.], shake the mixture occasionally for twenty-four hours. Finally, filter, and preserve the product in a well-stopped bottle. The specific gravity of this liquor is 1·593." *Dub.*

The chloride of zinc is made, in the usual way, by dissolving zinc in muriatic acid. The chlorinated lime is added in order to convert any iron present into sesquichloride, from which it is afterwards precipitated by the chalk. The use of this precipitant introduces into the preparation a little chloride of calcium, which is of no consequence. The two pints and a half of water, ordered in the formula, are not used in the process. They were probably intended to be added to the muriatic acid, which acts better on the zinc when diluted. The preparation is completed by bringing it to a certain bulk by the addition of distilled water, and by filtration to separate the precipitated iron and any excess of chalk.

Solution of chloride of zinc is a dense, colourless liquid, having a burning, nauseous taste even when dilute. It contains 175 grains of zinc in the Imp. fluidounce, and has the sp. gr. 1·593. This solution is equivalent to Burnett's disinfecting fluid noticed below. It is a powerful disinfectant, and, when applied, duly diluted with water, to cancerous and other offensive ulcers, destroys their fetor so long as the dressings are kept moist with it. The solution is recommended by M. Gaudriot in gonorrhœa in both sexes, as having remarkable remedial powers. For men he uses an injection, composed of from twenty-four to thirty-six drops in four fluidounces of water. A small quantity only is injected about an inch up the urethra, two or three times a day. For women he employs a vaginal suppository, formed of five drops of the solution, half a grain of sulphate of morphia, and three drachms of a paste consisting of a drachm and a half of starch, a drachm of mucilage of tragacanth, and half a drachm of sugar. The suppository is introduced every day, or every second day.

Burnett's disinfecting fluid, like the Dublin officinal solution, is an aqueous solution of chloride of zinc. It contains 200 grains of zinc in each Imperial fluidounce, and has the sp. gr. 2. It is, therefore, considerably stronger than the Dublin solution. It is so called after Sir William Burnett, who introduced it into use, in 1840, as a powerful deodorizing and disinfecting agent in neutralizing noxious effluvia, and in arresting animal and vegetable decomposition. Diluted with water it forms Sir William's patent preservative against the dry rot The concurrent testimony of a number of observers shows that it acts as an excellent disinfectant for ships, hospitals, dissecting rooms, water-closets, privies, &c. (See Extracts from the *British Navy Reports* on chloride of zinc as a disinfectant, in the *Lond. Med. Times and Gaz.*, Oct. 1853, p. 341.) Injected into the blood-vessels, it preserves bodies for dissection, without impairing their texture, and is said not to injure the knives employed; but the accuracy of the latter statement is doubtful. The advantage is claimed for it, that, while it destroys putrid odours, it has no smell of its own. For preserving

ZINCI OXIDUM. *U.S., Br. Oxide of Zinc.*

"Take of Precipitated Carbonate of Zinc *twelve troyounces*. Expose it, in a shallow vessel, to a low-red heat until the water and carbonic acid are wholly expelled." *U. S.*

"Take of Carbonate of Zinc *six ounces*. Place the Carbonate of Zinc in a loosely covered Hessian crucible, and expose it to a dull red heat until a portion, taken from the centre of the contents of the crucible and cooled, no longer effervesces when dropped into dilute sulphuric acid. Let the crucible cool, and transfer the product to stoppered bottles." *Br.*

Both the Pharmacopœias prepare the oxide of zinc from the carbonate already formed. By referring to the article on precipitated carbonate of zinc, *page* 1439, it will be found that it is obtained in the U. S. and Br. processes from sulphate of zinc, by the decomposing influence of carbonate of soda. Other methods of obtaining the carbonate of zinc are by the mutual decomposition of the chloride and carbonate of soda and of the sulphate and carbonate of ammonia; but the officinal plan is to be preferred. M. Lefort found it to furnish a carbonate which is washed with facility, and is convertible by calcination into a pure oxide, readily reduced to an impalpable and very light powder. (*Journ. de Pharm.*, 3e sér., xi. 329.) It is, besides, more economical. The carbonate of zinc, in whatever way obtained, is exposed to heat to drive off the carbonic acid and water, in order to obtain the oxide. According to Mohr, a full red heat is not necessary; a temperature between 536° and 572° being sufficient. It is probable that an unnecessarily high heat injures the oxide as a therapeutic agent.

Oxide of zinc may be obtained by the combustion of the metal; and in this way it was formerly prepared by the Dublin College. Zinc melts at 773°, and immediately becomes covered with a film of gray oxide. When the temperature reaches nearly to redness, it takes fire and burns with an intense white light, generating the oxide in the form of very light and white flocculi, resembling carded wool, which quickly fill the crucible, and are in part driven into the atmosphere by the current of air. The late Mr. G. D. Midgely, of London, several years ago, called attention to the production of oxide of zinc by combustion, and gave a description of the apparatus, by which he was enabled to prepare from one to two hundred weight of the oxide at one operation. It consisted of a large muffle, heated to redness in a suitable furnace, and supplied with zinc from time to time as the combustion proceeded. The necessary draught of air was conveyed from the muffle by a tube, passing through the top of the furnace, and terminating in a vessel of water, in which the portion of oxide carried up by the current was retained. The resulting oxide was freed from particles of metallic zinc by being passed through a sieve.

Properties. The officinal oxide of zinc is an inodorous, tasteless, yellowish-white powder, insoluble in water and alcohol, and anhydrous. As obtained by combustion it is perfectly white. It dissolves readily in acids without effervescence; and in potassa and soda, but not in their carbonates. Being anhydrous, it is insoluble in ammonia; but the impure oxide found in the shops, being generally hydrated, is soluble in that alkali. At a low white heat it fuses, and at full whiteness sublimes. When prepared by combustion it was formerly called *pompholix, nihil album, lana philosophica*, and *flowers of zinc*. Its neutral solution in acids should give a white precipitate with ferrocyanide of potassium and hydrosulphuret of ammonia. If the precipitate with the former test is bluish-white, iron is indicated; if black with the latter, lead is shown. Prepared by the old officinal process, namely, by precipitating sulphate of zinc with am-

anatomical subjects, one part of the disinfecting fluid to eighteen of water will form a solution of the proper strength. For disinfecting operations on a large scale, a pint of the fluid may be mixed with four gallons of water.

monia, it contains the subsulphate, the acid of which may be detected by dissolving the oxide in nitric acid, and precipitating by nitrate of baryta. Sometimes it is obtained by precipitating chloride of zinc with ammonia, in which case the oxide contains subchloride, easily detected by nitrate of silver. If it contain white lead or chalk, it will not be entirely soluble in dilute sulphuric acid, but an insoluble sulphate of lead or of lime will be left. If iron be present, brownish-red flocks of sesquioxide of iron will remain undissolved, when the muriatic solution of the oxide is treated with ammonia in excess. Oxide of zinc consists of one eq. of zinc 32·3, and one of oxygen 8 = 40·3.

The powder sold in the shops as oxide of zinc is often very impure. Sometimes the carbonate is substituted for it, showing that the exposure to a red heat has been omitted. In this case the preparation will effervesce with acids. Most samples contain a large proportion of subsulphate, showing that the discarded but productive process of precipitating the sulphate of zinc solution by ammonia has been employed. Again, other samples contain subchloride. These spurious oxides are pointed out by Mr. Redwood, of London, as occurring in the English market, and, no doubt, are sold in the shops of the United States. (See *Pharm. Journ.*, Jan. 1855, p. 301.) Unfortunately, a white oxide is preferred by purchasers, though whiteness is generally a sign of impurity; the officinal oxide being yellowish-white.

Medical Properties and Uses. This oxide is tonic and antispasmodic. It has been given in chorea, epilepsy, hooping-cough, spasm of the stomach dependent on dyspepsia, and other similar affections. Externally it is employed as an exsiccant to excoriated surfaces, sometimes by sprinkling it on the affected part, but generally in the form of ointment. (See *Unguentum Zinci Oxidi.*) The dose is from two to eight grains or more, repeated several times a day, and given in the form of pill.

Oxide of zinc, prepared by combustion, is extensively used in painting as a substitute for white lead, over which it has the advantage of not being discoloured by sulphuretted hydrogen. It has, moreover, the merit of not producing injurious effects on the workmen at all comparable to those caused by white lead. The oxide thus prepared, even though pure, should not be substituted for the officinal, as its state of aggregation is probably different.

Off. Prep. Unguentum Zinci Oxidi. B.

ZINCI VALERIANAS. *U. S.*, *Br. Valerianate of Zinc.*

"Take of Valerianate of Soda *two troyounces and a half;* Sulphate of Zinc *two troyounces* and *four hundred and twenty grains;* Distilled Water *a sufficient quantity.* Dissolve the salts separately, each in twenty fluidounces of Distilled Water, and, having heated the solutions to 212°, mix them, and set the mixture aside to crystallize. Decant the mother-water from the crystals, and put them upon a filter in a funnel to drain. Mix the mother-water and the drainings, evaporate at a heat not exceeding 200° to four fluidounces, and again set aside to crystallize. Add the crystals, thus obtained, to those in the funnel, wash the whole with a little distilled Water, and, having removed them with the filter, spread them on bibulous paper, and dry them with a heat not exceeding 200°." *U. S.*

"Take of Sulphate of Zinc *five ounces and three-quarters* [avoirdupois]; Valerianate of Soda *five ounces* [avoird.]; Distilled Water *a sufficiency.* Dissolve the Sulphate of Zinc and the Valerianate of Soda, each in two pints [Imperial measure] of the Water; raise both solutions to near the boiling point, mix them, cool, and skim off the crystals which are produced. Evaporate the mother-liquor at a heat not exceeding 200°, till it is reduced to four [fluid] ounces; cool again, remove the crystals which have formed, and add them to those which have been already obtained. Drain the crystals on a paper filter, and wash them with a small quantity of cold Distilled Water, till the washings

give but a very feeble precipitate with Chloride of Barium. Let them now be again drained, and dried on filtering paper at ordinary temperatures." *Br.*

These formulas are essentially the same as that of the late Dublin Pharmacopœia. In the formation of the salt a double decomposition takes place between the reacting salts, resulting in the production of valerianate of zinc and sulphate of soda. Upon mixing the hot solutions, crystals of the sparingly soluble valerianate of zinc form on the surface of the liquid; and, during the progress of its concentration to one-tenth, more of them are successively produced. These are then washed with cold distilled water to separate adhering sulphate of soda, drained on a filter, and dried.

Properties. This salt is in white, pearly scales, having a faint odour of valerianic acid, and a metallic, styptic taste. It dissolves in 160 parts of cold water, and in 60 of alcohol of 0·833. The solutions, which have an acid reaction, become turbid on the application of heat, but clear again on cooling. The salt, as obtained by the officinal formulas, is anhydrous; but, when formed by exactly saturating carbonate of zinc, made into a paste with water, with valerianic acid, it contains twelve eqs. of water, and, when dried at 122°, perfectly resembles the anhydrous salt. (*G. C. Wittstein.*) Sometimes acetate of zinc, impregnated with oil of valerian, is fraudulently substituted for this salt. The butyrate of zinc has been sold in Paris for the valerianate, and is so similar to it as not to be distinguished by its physical properties. The two salts, however, may be discriminated, by adding a concentrated solution of the acid of the suspected salt, obtained by distillation with sulphuric acid, to a concentrated solution of acetate of copper. If the acid is the butyric, its addition to the solution of the acetate disturbs the transparency of the latter, by the formation of a bluish-white precipitate; while, if the valerianic, no change is produced. (Larocque and Huraut, *Journ. de Pharm.*, 3*e sér.*, ix. 430.)
